SIR,—Dr. A. F. Hurst, in the instalment of his address on the constitutional factor in disease published on May 7th, raises some interesting points in connexion with the family incidence of nephritis, and also with regard to the possible prevention of recurrences in persons who have previously suffered from the disease. It is perhaps not generally recognized that the family incidence of nephritis is comparatively high. In a series of 69 cases of all types seen recently in which this question was carefully investigated, a history of the disease occurring in other members of the family was obtained in 19 instances, or 27.55 per cent. In a further series of 180 cases admitted to the wards of Guy's Hospital during the years 1921 to 1924 inclusive, a "positive" family history was obtained in 20 cases, or 11 per cent. In this series the point was probably not specifically asked for when writing up the case history in the majority of instances. In one family of 13 members of three generations 6, and possibly 7, persons had nephritis. The family quoted by Dr. Hurst must, however, be unique in the large number of members affected. Instances of acute nephritis occurring in more than one person in a family at the same time are occasionally seen, and are generally influenzal or streptococcal in origin.

Dr. Hurst also inquires whether the liability to develop nephritis in certain families depends upon a familial tendency to excessive acidity of the urine. This question is at present being investigated. There is some evidence to suggest that some such factor is present, but the problem is very complicated, and further work is needed.

Lastly, Dr. Hurst suggests that all individuals who have once had nephritis, but who have recovered therefrom, should take alkalis constantly in order to prevent recurrences. The work quoted by Dr. Hurst on *scarlatinal nephritis* indicates that such a procedure may be of use. It will be necessary, however, to do something more than render the urine permanently alkaline. The term "alkaline" is too vague. Dr. H. Carter and I found that by maintaining the urine (early morning specimen) at a *p*H of 7.7 throughout the illness in a large series of scarlet fever cases the incidence of nephritis and albuminuria was reduced from 5.5 per cent. in the controls to 0.6 per cent. If the alkalinity of the urine had been maintained at a higher point would the incidence of these complications have been still further reduced? At present we can only say that acute nephritis developing in a person whose urine is made more alkaline than normal by the ingestion of alkaline salts is usually of a very mild type, and clears up very rapidly. The same applies to acute exacerbations in chronic cases.—I am, etc.,

London, May 9th. A. ARNOLD OSMAN.

GOITRE PREVENTION.

SIR,—In the JOURNAL of January 15th (p. 94) is an article by Lieut.-Colonel McCarrison on an experiment in goitre prevention. It is extremely interesting to me that at last somebody has come forward and given evidence that the so-called lack of iodine had very little to do with goitre, its cause or treatment. That it has a certain action there is no doubt, but the fact remains that its role is only a minor one. For some years past I have been trying to emphasize the importance that infection has in goitre. In the issue of the *New York Medical Journal* for April 5th, 1922, and at the Medical Congress held in Melbourne in March, 1924, I have stressed this point. Repeatedly at the clinical meeting at hospital have I shown cases which have been cured by the removal of infections.

For a good many years I have been treating cases of exophthalmic goitre with success without any iodine, and in every instance I have not failed to bring about a cure where the focal infection could be completely eradicated. In the course of the last five years I have only found it necessary to resort to operation in one or two cases where adenoma was present. Even now, when men are turning their attention to focal infections, they are overlooking the nasal ones.

I sincerely hope that due notice will be taken of McCarrison's article and more attention paid to the infective factor in goitre than to the iodine question. If the infection is removed it will be found that there will be very little use for extra iodine.

We are all agreed that the thyroid is called into activity in the presence of infection, and under such conditions extra iodine is needed. If there should be a local deficiency all those with infections will be the first to show enlargement. Of all the work done in America, New Zealand, and other places there has been very little with regard to cure of goitre by the administration of iodine to school children. This alone should be quite sufficient evidence to show the small part it plays in the production of the disease.—I am, etc.,

SYDNEY PERN, M.R.C.S., L.R.C.P.Eng.

Melbourne, Feb. 24th.

POST-MORTEM EXAMINATIONS IN GENERAL PRACTICE.

SIR,—May I draw the attention of the profession to a matter of great moment both to it and to the public—namely, *post-mortem* examinations in general practice.

To the average general practitioner a necropsy is a nightmare and a thing to be avoided if possible.

If I may be pardoned for my presumption, I do not think the average general practitioner is experienced enough in *post-mortem* work to give a reliable opinion in many cases, and my belief is that he would be the first to welcome assistance. Am I going too far when I say that death certificates are sometimes given somewhat inaccurately, or without sufficient reason for the diagnosis, because the general practitioner knows that his refusal to certify would mean a *post-mortem* examination, which he would have to undertake? It is at least conceivable that crime goes undetected in this way.

Again, if we as general practitioners are compelled to undertake this work, and "toil all night and find nothing," how many of us are strong enough to go into the witness-box and confess our failure?

A short time ago an eminent pathologist in the witness-box said that, although he had conducted a *post-mortem* examination, he could not give an opinion as to the cause of death; but I am afraid this stand could only be expected from the eminent man, with whom the opinion of the masses as to his competence did not weigh.

Would it not be possible for the Government to formulate a scheme whereby each county or other division of the country would be provided with the services of a consulting pathologist, to whom all cases of doubt could be referred, possibly after consultation with the coroner, and who would be responsible for the *post-mortem* examination?

In my humble opinion this would take a load off the shoulders of the general practitioner and would be a safeguard to the public.—I am, etc.,

Bedworth, Warwickshire, May 7th. LIONEL E. ORTON.

*** Dr. Orton's opinion may be compared with that quoted from a letter by Dr. Cyril Helm in an annotation published on April 23rd (p. 769).

GENERAL MEDICAL PRACTICE AND THE MEDICAL CURRICULUM.

SIR,—Dr. Munro Kerr's address (May 14th, p. 870) contains matter of great importance. His main contention—that the student's syllabus is overloaded by surgery and midwifery at the expense of medicine—is true; and the dangers resulting from such overloading ar us.

The young general practitioner has al consult with the physician-teacher on an conceivable surgical aspect. So little time ha teacher to present his subject that it appear little more than a collection of gener principles, and he is apt to conclude tha and treatment of many obscure cases be laparotomy. If he is not fortunate enough intern he carries these ideas into practice physician-teacher, losing the double incent and practice, is too apt to hand over gr subject properly his own to the surgeon. surgeon is an operator, too often to the e ambition to be a doctor.

In a minor aspect the effect of the sy student, reinforced by the stimulating of by the majestic ritual of surgery, is to dri operative branch of the profession. Th become crowded. There is too much opera of it is bad and unnecessary. Surgeons are

Now, we are at that thrilling mome history when we find that many of the fou structure will have to be rebuilt. The mas this hard and inspiriting task are many of t the frontage defacing good stonework und that they are sculptors. The rest, ha most of the elements of their craft, are a efforts from the pavement.—I am, etc.,

Glasgow, May 15th.

STATISTICS OF TUBERCULO

SIR,—Dr. Ashforth (April 30th, p. 81 contradicted when he says that "statistics thing"; but when he goes on to say that of so-called cases of tuberculosis in the not tuberculosis," he is obviously grossly average population of the sanatorium. If the presence of tubercle bacilli in the sput evidence of tuberculosis—and that is not a will find that there are very few sanatorium where there are more than 30 per cent. of t no sputum or with a negative sputum. I with him as to the value of statistics, bu sceptical mind will find something suggestiv of the Registrar-General. These figures death rate from tuberculosis is half of wha more than a generation ago. As he is believer in sanatorium treatment, one wo him what type of cases have been sent b toriums in the past. The practitioner who in the sanatorium is usually the one who in the last stages of the disease, when eve been tried and has failed. But, if the s tried first, I have no doubt there would converts among the unbelievers.—I am, et

Grampian Sanatorium, Kingussie, May 16th.

TRAUMA AS A CAUSE OF AUR FIBRILLATION.

SIR,—My friend Sir James Barr has cas but I do not intend to rise. He asks me discussion as to the essential mechanism in of auricular fibrillation. This is outside t paper, which dealt only with the question—v strain might not on occasion be responsibl tion of fibrillation.

It is good to hear that Sir James Barr's system is still in such excellent fettle; a understand that, to him, fibrillation is dive its terrors, if, as he says, "it can be ar five minutes by the induction of the c contraction."—I am, etc.,

Liverpool, May 16th.

Medico-Legal.

LIBEL ON MEDICAL OFFICERS OF HEALTH.

BARNES AND FITZGERALD *v.* BURCHILL AND OTHERS.

At the Lancashire Easter sitting of the King's Bench Division, held at Liverpool on May 4th before Mr. Justice Roche, the terms of settlement were announced by counsel in the action brought by Drs. G. C. Barnes and W. Fitzgerald, respectively medical officer of health and deputy medical officer of health for Southport, against the proprietors of the *Liverpool Evening Express*. Mr. Rice Jones, on behalf of the plaintiffs, in informing his Lordship that the action had been settled, said that one of the terms of settlement was that each side should make a statement. Mr. Rice Jones then, by permission, read the following statement:

Counsel's Statement on Settlement of Action.

"In January last there was an outbreak of small-pox in Southport and the plaintiffs, in the course of their duty as medical officers of health for the borough, had to send persons suffering from small-pox to the Liverpool Isolation Hospital. During the prevalence of this epidemic the defendants printed and published on two occasions in their newspaper, the *Liverpool Evening Express*, paragraphs of a libellous nature affecting the plaintiffs as medical officers of health and as physicians. Furthermore, the defendants drew particular attention to these statements by means of a printed poster of the type ordinarily used by them for the purpose of advertising their newspaper. In view of these publications the plaintiffs claim damages for libel.

"The first of these paragraphs appeared on January 19th and read as follows:

"NOT SMALL-POX AFTER ALL.

"*Some Southport Cases Breathe Again.*

"The relief felt in Southport that the spread of small-pox in the town is abating is increased to-day by the news that out of 20 supposed sufferers sent to the Isolation Hospital a number have been returned suffering only from chicken-pox. Another child notified as suffering from a mild attack of small-pox was sent from Southport to the Isolation Hospital last night. The number of genuine cases of small-pox is now about 13.

"'There is every hope now that the epidemic is dying out,' said a Southport doctor to an *Evening Express* representative to-day. 'Chicken-pox unfortunately is prevalent in the town at the same time, and no doubt through over-anxiety to stamp out the epidemic sufferers from chicken-pox have been sent away as suspects. It is as well to be on the safe side. Chicken-pox is easily distinguishable from small-pox, but the nature of this epidemic has been a mild attack of the disease.'

"This was followed on January 22nd by a second paragraph in these words:

"SOUTHPORT SMALL-POX.

"*Four Fresh Cases sent into Hospital.*

"A further outbreak of small-pox has occurred in Southport. The Southport health authorities report that four fresh cases were removed to an isolation hospital in Liverpool last night. Three are children, two boys and a girl, and the fourth is an aged man. This brings the total number of cases to 18, a number of suspected cases who had been previously sent away being brought back, chicken-pox having been diagnosed. The fresh cases diagnosed are reported to be of a mild character.

"These statements made an unfortunate impression in Southport at the time, and had they been true they would tend to imply that the plaintiffs had made wrong diagnoses and exposed persons suffering only from chicken-pox to the risk of infection with small-pox. In fact, the statements were totally untrue and without the slightest foundation. All the cases sent to the Isolation Hospital at the date of the publications were cases of small-pox and were retained there as such, and in no instance was a case of chicken-pox diagnosed as small-pox. The effect of these untrue statements was to hinder the plaintiffs in their very anxious duty as medical officers of health, and it is of the utmost importance not only to themselves, but to the public generally, that the true facts of this matter should now be made known.

"The defendants have admitted that the publications complained of were untrue, and with the view of alleviating to some extent the continuing damage resulting from the prevalence of these false rumours, they caused an apology to be published in their newspaper on January 28th."

Counsel read the text of the apology, and stated that the defendants had also paid into court a nominal sum of £100 as damages, and they had agreed to pay the plaintiffs' costs as between solicitor and client. He added that although the plaintiffs had suffered considerable damage and inconvenience, it was not their desire to profit pecuniarily by the proceedings which they had felt themselves compelled to institute, their only wish being to vindicate their professional reputations. Accordingly, in view of the defendants' explanation that the statements were published by mistake, the plaintiffs were prepared to accept their apology, together with the nominal sum paid into court, and intended to hand over the £100 to some charitable institution.

Mr. Sellers (counsel for the defendants) said that on their behalf he could add nothing to the apology, expression of regret, and unreserved withdrawal which they had made at the earliest opportunity after their attention was drawn to the words complained of and to the possible construction which might be put upon them; but the defendants readily availed themselves of the publicity which a statement in court gave to repeat that apology and to say that the statements were not intended to reflect in the slightest degree upon the plaintiffs. The defendants withdrew unreservedly any imputations against the plaintiffs' characters which the statements might be construed to contain, and expressed again their regret for any inconvenience or annoyance occasioned to them by the publication.

Mr. Rice Jones then asked his lordship for judgement on terms endorsed on counsels' briefs, and an order that the £100 paid into court should be paid out to the plaintiffs, and Mr. Justice Roche, in consenting, said that this was a very proper ending to the matter.

ACTION IN RESPECT OF TONSILLECTOMY.

On May 9th an action was heard before Mr. Justice Brown and a special jury against Mr. Isaac A. Davidson, M.D., B.Ch., assistant surgeon to the Benn Ulster Eye, Ear, and Throat Hospital. A girl, aged 6, had been attending the corporation school clinic, and her parents had been advised to have the tonsils removed; she was brought to the above-mentioned hospital for further advice and operation. Mr. Davidson removed the one tonsil, but in trying to remove the other he found that it was adherent and could not get it away; he then observed that in his efforts to remove the second tonsil he had removed a bit of the uvula. It was alleged that after the child was brought home she was unwell and complained of her throat; when she took water it came back through the nostrils; when tired she talked with a nasal tone; and that she could not take solid food. Dr. Lee, who attended the child, said that she was not delicate; he found one tonsil efficiently removed, the other not removed and the uvula gone.

Mr. Davidson, in giving evidence, said that he had been connected with the Benn Hospital for more than twenty years, and had performed the same operation perhaps 10,000 times. This operation he performed on November 13th, 1926; the right tonsil was adherent, and on the following morning he noticed that part of the uvula had been removed; the patient progressed in the usual way; the operation was successful and the results were quite good; he had removed the uvula in singers and speakers, and the loss would cause no harm to the little girl; he did not believe that the child could not drink properly.

Mr. W. M. Killen, M.D., M.Ch., senior surgeon to the Benn Ulster Eye, Ear, and Throat Hospital, said that the operation was substantially the same as that which he practised himself; there was no method of ascertaining whether the tonsil was adherent or not before operation; he had never heard or read of any harm coming from the removal of the uvula; the child was in delicate health before the operation, as the mother said that she postponed coming for it till the child should get stronger.

Mr. J. A. Craig, F.R.C.S.Eng., senior surgeon to the Eye, Ear, and Throat Department of the Royal Victoria Hospital, Belfast, and lecturer on these subjects in the Queen's University, said the method adopted by Mr. Davidson was that generally adopted at the present day; the removal of the uvula would not, in his opinion, retard the recovery of the child.

The action was brought by the child's father, and heavy damages were claimed. The jury found that the defendant had exercised reasonable care and skill in performing the operation, and judgement was entered for him accordingly.

AN OSTEOPATH'S FEES.

THE decision given by the Marylebone county court judge that an osteopath could not recover fees for treatment undertaken by him—reported in the BRITISH MEDICAL JOURNAL of March 5th (p. 448)—was appealed against before Acton and Talbot, JJ., sitting as a divisional court in the King's Bench Division on May 16th.

Their lordships ordered a new trial on the ground that they were bound by the decision of Horridge and Shearman, JJ., sitting as a divisional court, on appeal from a county court judge's decision, in the case Hall *v.* Trotter, that an osteopath was entitled to recover fees for treatment rendered. Leave to appeal was given.

The plaintiff, Mr. E. L. Macnaughten, of Weymouth Street, London, claimed £30 9s. for osteopathic treatment for nervous disability and facial neuralgia rendered by him to the wife of the defendant, Mr. C. H. Douglas. The defendant relied upon the provisions of Section 32 of the Medical Act, 1858:

"*No person shall be entitled to recover any charge* in any court of law for any medical or surgical advice, attendance, or for the performance of any operation, or for any medicine which he shall have both prescribed and applied, unless he shall prove upon the trial that he is registered under this Act."

The county court judge held that as the plaintiff was not a registered medical practitioner he could not recover fees for treatment, and entered judgement for the defendant, with costs. The plaintiff appealed to the divisional court.

Mr. A. C. Jackson, counsel for the appellant, said Mr. Macnaughten was a graduate of Trinity College, Dublin, in subjects other than medicine, but he also possessed an American degree of Doctor of Osteopathy, a profession recognized in America. The claim was for manual treatment and not for advice given, as the defendant's wife was perfectly well acquainted with the nature of osteopathic treatment when she first came to him for treatment. In Hall *v.* Trotter it had been held that in almost exactly similar circumstances an osteopath was entitled to recover fees for treatment rendered, and, therefore, the Marylebone county court judge was wrong here in holding that Section 32 of the Medical Act, 1858, applied to treatment of this kind.

Mr. L. Payne, for the respondent, urged that the plaintiff was not entitled to recover fees for treatment which usurped the functions of a medical man. The plaintiff's occupation was analogous to that of a masseur, who might be able to recover for

treatment in certain circumstances, but not in a case where he had been called upon to give advice.

In his judgement Acton, J., said the question was undoubtedly one of some importance and one which at first sight might appear to present some little difficulty. The very question, however, had been raised before and decided by a divisional court in Hall *v.* Trotter, where the plaintiff had a diploma from an American college of osteopathy, but was not registered as a medical practitioner in this country. It was to be regretted that the facts in Hall *v.* Trotter were not fully set out in the report, as it would have been useful to know whether the plaintiff there undertook any diagnosis, or gave any advice, as distinct from actual manual, or manipulative, treatment; and, if so, how far his claim was based upon the former. In that case the county court judge had held, and the divisional court had confirmed his decision, that osteopathy was treatment that did not fall within Section 32 of the Medical Act, 1858. However, from the report it appeared that arguments similar in substance to those relied upon in the present case had been addressed to the court. One of the judges, Horridge, J., had said: "In his view of the findings of the county court judge the plaintiff did not give an advice. She gave certain treatment to the bodies of these three persons. He declined to be led into definitions. He was satisfied that the case did not fall within the Act." The other judge, Shearman, J., had agreed: "The plaintiff applied her knowledge of anatomy to help her to determine the part of the body to which she should apply the treatment she had been specifically called in to give . . . he thought the county court judge here was right, but he was far from saying that anyone who chose to call himself an osteopath could charge for any service which he chose to render." His lordship said it might be that if the plaintiff's charges were analysed, and if it were proved that any part of those charges was for advice given, the plaintiff would not be able to recover in respect of that portion. The plaintiff's claim, however, had been wholly barred by the county court judge. In view of Hall *v.* Trotter, it was not open to that court to do other than follow that case, and, therefore, they would order a new trial, but he (his lordship) would express no opinion whether the plaintiff's claim could be divided into charges for manual treatment and charges for advice.

Talbot, J., in concurring, said a very strong argument in support of the county court judge's judgement might have been urged but for the decision of a divisional court in Hall *v.* Trotter, which he regarded as a binding one.

Obituary.

JAMES DUNCAN MACLAREN, M.D., F.R.F.P.S.G.;

Formerly Physician to the Royal Infirmary, Glasgow.

THE death occurred on May 10th, at his residence, Dunreggan, Elie, Fifeshire, of Dr. J. D. Maclaren. He was in his 95th year, and had been a fellow resident of Lord Lister in Edinburgh Royal Infirmary. He was born in Stirlingshire and studied both at Glasgow and Edinburgh Universities; at the latter he graduated M.D. in 1854 with a thesis on the nutritive process. In the winter session 1854-55 he acted as house-physician in Edinburgh Royal Infirmary to the professors of clinical medicine. These were Alison, Christison, Hughes Bennett, and Simpson, of whom he had many memories and anecdotes. His fellow residents included Dr. J. Beddoe, Dr. (later Sir John) Kirk, Joseph (later Lord) Lister, Dr. David Christison, and Dr. (later Sir Patrick Heron) Watson. Immediately after his term of office as a resident, Dr. Maclaren went to the Crimea, where the troops were at that time greatly in need of medical assistance. He served both at Scutari and as assistant physician to the civil hospital at Renkioi in the Dardanelles. For a period he also acted as company commander to troops, since there was a shortage of officers. On his return to this country after the Crimean war Dr. Maclaren settled in practice in Glasgow, where he ultimately became physician to the Royal Infirmary. He took up the practice of the late Professor Harry Rainy, the father of Principal Rainy, and practised medicine at Glasgow during half a century. Dr. Maclaren was the senior member of the Faculty of Physicians and Surgeons in Glasgow, which in 1924 elected him an honorary Fellow. He had taken the licentiateship of the Royal College of Surgeons of Edinburgh in 1854, and had become an ordinary Fellow of the Royal Faculty of Physicians and Surgeons of Glasgow in 1866.

Both in Glasgow and after his retirement Dr. Maclaren took a great interest in the affairs of the United Free Church. In 1858 he had been appointed session clerk of Claremont Church, Glasgow, of which his brother was the minister, and after his retirement, when he went to reside in Elie, Dr. Maclaren was session clerk of Elie United Free Church. This office he held till his 89th year, when increasing blindness compelled him to resign; two or three years ago he attended regularly the general assembly of the United Free Church. Dr. retired from active practice some twenty-two y he travelled extensively and twice went round t He was a man of wide culture and interests, and reader. His interest in every recent work on biography, or politics as it appeared was continu after increasing failure of vision necessitated the a reader, and his keenness of intellect and remained to the end of his life. He continued a of the British Medical Association until last Sep when he resigned. His vitality was surprising for of his years. Living at Elie, he was a member Golf House Club for over twenty years. He playe regularly, and could beat many younger men, unt ago of 85. Some three years ago he underwent a s operation for calculus, but made an uninterrupted rec Dr. Maclaren had been a widower for many years; h a family of five daughters, of whom three survive The interment took place at Tillicoultry on May 13th.

THE LATE PROFESSOR E. H. STARLING.

SIR WILLIAM HALE-WHITE writes: The admirable acco of the late Professor Starling in your last issue pron me to add something to what Dr. C. J. Martin says ab his clinical work. At the end of his studentship at Gu Hospital Starling obtained the Treasurer's Gold Medal Clinical Medicine and was *proxime accessit* for that Clinical Surgery. He became my house-physician in 188 and I never had a better. He had a marvellous flair, n only for the science, but also for the art of clinical medicin If he had chosen medicine for his life's work he woul have become one of the chief among the really grea physicians. He never lost his clinical aptitude. Whe war broke out he came, saying that he proposed to g round the wards with me to furbish up his medicine. Although he had done no clinical work for twenty-four years, he picked it up at once; in a fortnight he was as good at it as when he finished his house-physiciancy, and he went forthwith to take charge of patients at the Herbert Hospital. His interest in medicine remained throughout his life, for he would always discuss with enthusiasm how his physiological work helped the elucidation of medical problems. It has been my happiness to have known him and to have seen much of him during the past forty years. There was no greater pleasure than that of talking to him—he was so alert, so interested in everything. He could not be dull; in a few words he got to the root of the matter and illuminated the whole subject, whatever it might be.

The following well known foreign medical men have recently died: Dr. SCHICKELE, professor of clinical gynaecology at Strasbourg University; Professor PAUL REGNARD, director of the Oceanographic Institute founded by the Prince of Monaco and member of the Académie de Médecine; Professor EUGENIO PIRONDINI of Parma, one of the founders of the Italian Society of Urology; Professor GAVELLO, an otologist of Turin; Dr. SALVADOR CARDENAL, honorary professor of surgery in the University of Barcelona, aged 74; Dr. J. DE BRUIN, professor of clinical pediatrics at Amsterdam; Dr. JULES BOECKEL, honorary professor of the Strasbourg faculty of medicine and Commander of the Legion of Honour, aged 78; Dr. MARCEL BRIAND, a leading Paris alienist and for nearly thirty years medical superintendent of the Villejuif Asylum; Dr. JULIUS POHL, formerly professor of pharmacology at Breslau; Dr. M. HOFMEYER, formerly professor of pharmacology at Würzburg; Professor ALEXANDER TIETZE, a leading Breslau surgeon; Professor UHTHOFF, formerly director of the ophthalmological clinic at Breslau, aged 74; Dr. BARFURTH, formerly professor of anatomy at Rostock, aged 78; Dr. PERETTI, formerly professor of psychiatry at Düsseldorf, aged 75; Dr. HERMANN VON TAPPEINER, professor of pharmacology at Munich; and Professor GEORGE SUMMER HUNTINGTON, professor of anatomy at Columbia College and joint editor of the *Journal of Anatomy and Physiology*.

Medical Notes in Parliament.

[FROM OUR PARLIAMENTARY CORRESPONDENT.]

THE House of Commons has been engaged this week in further discussion of the Trade Disputes and Trade Unions Bill and on the second reading of the Finance Bill. In the House of Lords Lord Arnold opened a debate on the use of white lead paint, but no new declaration of policy resulted. Arrangements were made for Lord Dawson to address an open meeting of members on May 19th regarding the use of animals in medical research.

Optical Practitioners' Registration.

IN the House of Commons on May 13th Mr. West Russell moved the second reading of the Optical Practitioners (Registration) Bill. He said this was the only country in the world with no legislation on the registration of opticians. There was such legislation in Australia and in every State of the U.S.A. At present in this country more spectacles were worn by adults and children than were worn a few years ago. This was largely due to the voluntary efforts of the opticians. The principle of State registration had been accepted and was in operation with success in some other professions. It was said on good authority that something like 15,000,000 people in this country had defective eyesight. In industry at present were some 4,000,000 suffering from short sight or some defect of eye construction. Something like 24.8 per cent. of school children suffered from defective sight. The Council of the British Optical Association and the Council of the Spectaclemakers Company formed the Joint Council of Optical Practitioners, and this had registered something like 3,500 opticians of whose qualifications some guarantee was given. The Council's course of training and preparing entrants enabled opticians not only to test the eye and to provide the spectacles which were necessary, but also to equip them with a knowledge of the construction of the eye and of the matters pertaining to it. The training of this useful body of men to deal with the problem of defective eyesight was being carried on by these voluntary associations. The Joint Council of Qualified Opticians had been founded because, in 1923, when ophthalmic benefit was first provided under the National Insurance Act, there had been no body to administer it. That benefit was now administered by the Joint Council of Qualified Opticians. Under the second valuation £2,000,000 would be distributed in five years for ophthalmic benefit, yet no authority was established by law to control and direct that sum. There was nothing in the bill to hinder anyone who was carrying on the work of an optician from doing so. The bill would merely enable the public to distinguish men of whose qualifications some guarantee was given by a responsible body. It would tend to eliminate quacks and mere sellers of spectacles. Mr. Russell remarked that, as one might expect, the most serious opposition to the bill came from the medical authorities, who, he understood, objected that it would give a status suggesting to the public that the registered optician was capable and qualified to deal with all matters concerning the eyes. But of defective eyesight 95 per cent. was due entirely to error of refraction and only 5 per cent. was due to disease or other cause. While it was true that an optician might not be able to diagnose the disease of the eye or to discover the source of the eye trouble, his training would enable him to detect the cases which were not to be dealt with merely by spectacles, but passed on to some medical authority. At the present moment most of this detection was done by opticians and not by medical practitioners. In health insurance it was necessary for the panel doctor to give a letter authorizing the provision of medical benefit. In the vast majority of cases the letter simply authorized a person to go to an optician to have his eyes tested and glasses provided. It was doubtful whether, comparing the general knowledge of the medical practitioner with the specialized knowledge of the optician, he was better fitted to deal with these cases.

Mr. Roy Bird seconded. He said that during the war the British Optical Association, at the request of the War Office, formed centres at home and on all the fronts, where qualified opticians not only dealt with spectacles and with sight, but in many cases administered drugs without medical supervision. The registered members of the Joint Council of Optical Practitioners numbered 3,000, but only 700 men appeared on the register of the British Medical Association as ophthalmic surgeons. Fifty per cent. of those on that list did not specialize in the eyes and diseases of the eye, but at some time had held an appointment or possibly had written a paper dealing with the eyes. Another 25 per cent. had no special qualification which was shown in the *Medical Register*. The medical profession said that 700 men could deal with the whole eyesight in this country, but in 358 towns only 397 qualified ophthalmic surgeons were practising. Ophthalmic surgeons were congregated either in the West End of London or in the big provincial towns and famous health resorts. The medical profession were claiming a physical impossibility in asking that qualified ophthalmic surgeons should look after the [illegible] Bird said he would have been happier [illegible]ich prohibited the sale of glasses or [illegible]uacks. The bill did provide for the [illegible] and a subsection provided for the [illegible] who had been engaged in the practice of optometry for five years before the commencement of the Act and who also passed a practical examination in optometry. A right of appeal to the High Court was provided, which he commended to the notice of the medical profession. The Board was to be nominated by the Ministry of Health and to represent not only the opticians, but also the Ministry of Health, the General Medical Council, the Scottish Board of Health, and the Board of Education.

Dr. Vernon Davies moved an amendment asking the House to decline to give a second reading to the bill as its subject matter was being investigated by a departmental committee. He said that members associated with him felt they must point out that the bill was *sub judice* and that two members of Parliament were sitting on the inquiry. In the opinion of his friends the bill was bad and impossible to work. Within recent years there had been an epidemic of applications for registration by societies of practitioners. The Joint Council of Qualified Opticians consisted of a little over 3,000 members, yet 30,000 persons in the United Kingdom obtained the whole or part of their living from practice as oculists. The Institute of Chemist Opticians, 5,000 in number, said the Joint Council of Qualified Opticians had no right to speak for the rest of the profession, and that they themselves were alone qualified by statute. An ophthalmic surgeon of very long experience said he never knew any patient to go into a spectacle shop and come out without spectacles. The medical profession adopted a very definite attitude. It said that training for the treatment of eye diseases called for special and prolonged study. Mr. H. Williams, intervening, asked how long the ordinary medical student devoted to the study of the eye. Dr. Davies said he undertook a course of lectures and made practical attendances at hospital. Practically all the ophthalmic surgeons in the country had extended post-graduate training as house-surgeons in eye hospitals. If a bill were introduced setting out the qualifications and training of opticians it would have a claim on the attention of the House, but this bill was vague and impracticable. He questioned whether the training which opticians got was sufficient to enable them to detect all kinds of eye diseases. The great difficulty had been the shortage of ophthalmic surgeons and the very high fees that were charged. Opticians did treat such cases as inflammation of the eye, chemist-opticians particularly.

Sir George Berry seconded the amendment. He agreed that the public should be enabled to discriminate between the skilled optician and the less skilled. At present the different societies examined their members who got the right to put letters after their names indicating that they had undergone a test according to the requirements of the society. This ought to suffice in the public interest. Many opticians contended that unless there were suitable correction of optical defects, serious damage would be done to the eyes. In his experience he had never known spectacles, however unsuitable, do any damage at all. Discomfort could be caused, but to say there was actual danger to the eye was an exaggeration. The positive effects of getting suitable spectacles were good and justified having the services of opticians, but they did not justify this bill, which was calculated to arouse in the public a mistaken sense of security. The skilled optician was perfectly competent to undertake the correction of optical defects, and his skill could be acquired in a few weeks or months. The optician might discriminate between defects due to diseases of the eye and optical defects, but not without being liable to make many mistakes, unless he had the full training of a medical man. Owing to the complexity of the eye the medical curriculum required the student to take up diseases of the eye only in the last six months of the time devoted to his studies. Mr. Barnes supported the amendment on the ground that Parliament should review the post-war tendency of a number of professions to seek privileges which would make them close corporations. Mr. Meller, in supporting the bill, said that Dr. Davies and Sir George Berry had spoken with great fairness. He declared that the instruction which the ordinary medical practitioner received in treatment of the eye was considerably less than that given by institutes now training opticians. The bill proposed to do what was done under the Dentists Act. The Board of Examiners under the bill was to include ophthalmic surgeons. He himself had to deal with thousands of applications for medical benefit, and after testing the advice given by medical practitioners he confidently supported the bill.

Mr. Rhys Davies supported the amendment. He said the British Medical Association took the usual attitude towards the problem, the attitude of malignant opposition to progress of any kind. The members of the British Medical Association did great service to the community, but when any other organization proposed to touch its preserves it at once became the mightiest and most influential trade union in the country. The doctors had taught the lesson that when funds were in hand they must be dipped into by someone. In 1912 they declared a strike, even in breach of contract. If Dr. V. Davies would induce the British Medical Association to join the Trade Union Congress then they would all work together. Mr. H. Williams pointed out that Mr. Rhys Davies was a member of the Departmental Committee now considering the registration of opticians. Sir Kingsley Wood said it was impossible to give an exact estimate of the number of persons suffering from defective eyesight, but among school children the figure was fairly constant at 10 per cent., though last year a slight improvement had been reported. On that basis it might be calculated that about 8,000,000 persons in the country required some aid by glasses. It was true that in an appreciable number of cases great harm might be done by an optician qualified in his own work but lacking medical knowledge, but how far that argument was valid could only be ascertained by full inquiry. Impartial inquiry was the more important as the sum allocated for ophthalmic treatment and optical appliances under the National Insurance Act was now £420,000 a year. He asked the promoters of the bill not to proceed with the second reading. Mr. Russell asked leave to withdraw the bill. Dr. Davies asked leave to withdraw the amendment. Sir Richard Barnett said that Sir George Berry's assertion that no kind of spectacles could injure a man's sight was amazing and had been at once challenged by the House. Mr. Tom Shaw said that if the bill passed the price of spectacles would probably increase, but every man or woman who went to a

skilled optician would have a chance of knowing whether there were anything seriously wrong with the eyes. Mr. A. V. Alexander spoke of the desire of the co-operative societies to retain the right to maintain optical departments.

The motion for the second reading of the bill was then negatived.

Shop Acts, 1920 and 1921.

The Departmental Committee which is inquiring into the working of the Shop Acts, 1920 and 1921, met at the Home Office on May 11th and 12th.

Mr. J. Hallsworth (Industrial General Secretary of the National Union of Distributive and Allied Workers) said that it was impossible, without the compelling force of a generally applicable early closing law, to protect and safeguard the health and comfort of those engaged in retail distribution.

Witnesses for the National Federation of Retail Fruiterers urged a general closing order for all trades of 8 o'clock on week nights and 9 on Saturdays, without exemptions. They said that, thanks to the medical and other scientific advice, fruit was no longer considered a special luxury. It was becoming a regular daily article of diet. In 1926 £2,000,000 worth or more of fruit was consumed.

Mr. E. D. Roberts, one of the witnesses, said that his experience was that girls who came into the fruiterer's trade weakly and anaemic became strong and healthy.

Small-pox.

Sir Kingsley Wood, answering Mr. Thurtle, said that up to May 11th 28 cases of small-pox in England and Wales had this year ended fatally. Of these, 21 were unvaccinated at the time of infection; 7 had been vaccinated in infancy. Of these latter the ages at the time of attack were 22, 23, 44, 50, 54, 58, and 62. He had no reason to doubt that all the cases were small-pox. Dr. Watts asked whether the types of cases in the last few months had been more virulent than for some time. Sir Kingsley Wood said he had seen a statement to that effect. Answering Mr. Harrison, Mr. Chamberlain said that in the fifty-two weeks ended April 2nd, 1927, 12,922 small-pox cases were notified in England and Wales. In the year ended March 31st, 1927, 32 deaths were classified as due to small-pox, and in another case small-pox was one of the causes of death. Mr. Harris asked whether some of the cases were not supposed to be chicken-pox. Mr. Chamberlain said some people would believe a case of small-pox to be anything but that. He added that he was obtaining full information on the number of local authorities in England and Wales who had no permanent buildings which could be used for dealing with an outbreak of small-pox. In due course this information would be published. Mr. Groves asked whether, as the small-pox cases removed from Hendon and Golders Green were originally reported as very mild, the Minister could throw light on the fatal result of half of them. Mr. Chamberlain did not know of such reports. He said the first case was relatively mild, but most of the others were severe. Mr. Groves asked whether the regional medical inspectors, when called in to diagnose cases of suspected small-pox, received a fee. Mr. Chamberlain replied that the question did not arise, as it was no part of the duties of regional medical officers of the Ministry to assist in such diagnoses.

On May 17th Sir Kingsley Wood stated that twenty persons contracted small-pox in the county of Durham in 1924. In 1925 there were 1,138 cases, and in 1926, 6,645. In reply to further questions, he said he could not state how many of the cases were children, how many had not been vaccinated, nor in how many instances the disease was originally contracted abroad.

Sickness in the Royal Navy.—Answering Sir Bertram Falle, Mr. Bridgeman said that in 1924 five cases were invalided from the navy for nephritis and one for stone in the kidney. Particulars of subsequent cases were not available. There had been an inquiry to determine whether distilled water was detrimental to health, but no evidence was available that it was a factor in the causation of disease. Distilled water produced in ships underwent considerable aeration before it was consumed. In a further answer to Sir B. Falle, Mr. Bridgeman said in 1924 20 boys, Royal Navy, were admitted to sick quarters and hospital for "rheumatism" and kindred complaints; in 1925 11, and in 1926 13. Such cases were kept under observation, and the figures did not show there was any increase. The medical department were diligent in the matter, and he understood it to be satisfied that there were no unusual circumstances causing this disability. Dr. Vernon Davies asked how many of these cases were invalided out with heart disease. Mr. Bridgeman asked for notice of the question. Mr. Groves asked the Minister of Health whether, in cases of infectious disease where there was uncertainty regarding the complaint and the medical officer was called in to decide, the patient's doctor or the medical officer received the notification fee. Mr. Chamberlain said that in such a case the medical officer of health would not be entitled to a notification fee, but if the patient's doctor notified the case he would receive the usual fee.

The University of London Site.—On May 17th the Financial Secretary to the Treasury stated that the University of London had arranged to purchase the Bloomsbury site from the Duke of Bedford, but he was informed that no contract had yet been signed. The Chancellor of the Exchequer had informed the House on November 9th last that he promised, in June, 1926, on behalf of His Majesty's Government, that they would be prepared, within certain financial limits, to ask Parliament to make provision for improved accommodation for the University, subject to the Treasury approval of plans to be form Senate. No official intimation had yet reached He could only say that the amount which Parliar asked to provide towards the improved accomm University would be approximately half the pric Government for the Bloomsbury site, which was £

M.B.—H. L. Wilson.

UNIVERSITY OF LONDON.

UNIVERSITY COLLEGE CENTENARY CELEBRA

THE celebration of the centenary of University Col will be inaugurated by the King and Queen, who College on the afternoon of Thursday, June 23rd; on of the following day the Great Hall will be dedica Arthur of Connaught, who will receive the delegate whom addresses will be presented. On Saturday the be occupied by lectures and demonstrations, and in t there will be a garden party at Perivale, where are th sports ground of the College. On Monday evenin a conversazione will be held, and on the followi afternoon there will be a special thanksgiving ser minster Abbey; in the evening of the same day the H. A. L. Fisher, who was President of the Board when the Bloomsbury site was originally offered to t and is now Warden of New College, Oxford, will give t Oration. On Friday, July 1st, the Master and Wa Worshipful Company of Drapers will give a luncheon A centenary play will be given on three evenings, and July 2nd, there will be a dance in the Great Ha morning, with the exception of Thursday and Saturd week ending July 2nd there will be lectures and demo

VICTORIA UNIVERSITY OF MANCHESTER.

THE Dauntesey Medical Senior Scholarship has been awarded to W. W. Kay.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.

AN extraordinary comitia of the Royal College of Physicians of London was held on May 12th.

Fellowship.

The gentlemen elected on April 28th (BRITISH MEDICAL JOURNAL, May 7th, p. 859) were admitted to the Fellowship.

Junior Standing Counsel.

The Registrar reported that Mr. C. Stafford Crossman had accepted the post of junior standing counsel to the College.

Medical Science Abstracts and Reviews.

A letter was read from the secretary of the Medical Research Council regretting the inability to resume the publication of *Medical Science Abstracts and Reviews*.

Delegates.

It was reported that Dr. S. W. Wheaton had consented to act as the delegate of the College to the third Imperial Social Hygiene Congress.

Dr. L. S. T. Burrell was appointed the delegate of the College to the thirteenth annual conference of the National Association for the Prevention of Tuberculosis.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

AN ordinary Council meeting was held on May 12th, when the President, Sir Berkeley Moynihan, Bt., was in the chair.

Diplomas of Fellowship were granted to Mr. George Frederick Gibberd and Mr. Arthur Joseph Wrigley, who have now complied with the regulations.

Mr. Cecil Fowler Beadles and Sir Henry John Gauvain were introduced and were admitted Fellows of the College.

Diplomas of Membership were granted to 163 candidates, of whom 28 were women.

A report from the Nomination Committee was received on the Primary Examination. It was decided that at present no alteration be made in the subjects of the Primary Examination for the Fellowship. The following recommendation of the Nomination Committee was adopted:

> That it is desirable to send examiners to the Dominions to conduct a Primary Examination for the Fellowship of the same standard as the examination in this country on conditions to be hereafter determined, provided that satisfactory arrangements can be made.

The President reported that the new by-laws had been approved and signed by the Secretary of State for Home Affairs, the Lord Chancellor, and the Lord Chief Justice.

Mr. E. Miles Atkinson was presented with the Jacksonian prize for the year 1926, together with a document declaratory of the award.

Mr. Herbert Cecil Malleson, winner of the John Tomes prize for 1924–26, and Mr. Robert Gordon Wilbond, appointed Begley student, were also introduced.

Jacksonian Prize.

The subject selected for the Jacksonian prize for 1927 is "The pathology, diagnosis, and treatment of bronchiectasis and abscess of the lung." The amount of the dividend received from the trust is £19 10s. The dissertations for the prize must be delivered to the secretary at the College by 1 p.m. on Saturday, December 31st. As already announced the subject for the 1928 prize is "The surgical treatment of pulmonary tuberculosis," for which the dissertations must be received at the College by 1 p.m. on Monday, December 31st, 1928.

Medical News.

A DISCUSSION on the function and distribution of haemoglobin and related substances in living organisms was opened at the meeting of the Royal Society on Thursday, May 12th, by Professor J. Barcroft, F.R.S., who reviewed the recent work on haemoglobin and related substances; he was followed by Dr. H. Hartridge, F.R.S., and Mr. F. J. W. Roughton, who dealt with the measurement of velocities of reaction of haemoglobin with other substances; by Dr. D. Keilin, on the cytochrome in animal and plant cells; by Mr. R. Hill, on the structure and preparation of haemoglobin and its chemical precursors; by Professor H. Munro Fox, on haemoglobin analogues in the blood of certain polychaete worms; and by Mr. J. B. S. Haldane, on the effect of carbon monoxide on plants and insects containing no haemoglobin. The discussion was brought to an end by Sir Frederick Hopkins, F.R.S., who stated some general conclusions.

THE Far Eastern Association of Tropical Medicine was instituted to serve as a means of co-ordinating the medical, dental, and veterinary professions of the countries of the Far East in the promotion of the science and art of tropical medicine and the instruction of public opinion in the prevention of disease. Congresses have already been held at Manila (1910), Hong-Kong (1912), Saigon (1913), Java (1921), Singapore (1923), and Tokyo (1925). At the invitation of the Government of India the seventh congress will be held this year at Calcutta from December 5th to 22nd, when Major-General T. H. Symons, C.S.I., Director-General of the Indian Medical Service, will preside. Scientific sessions will be held at Calcutta during the first week of the congress, after which excursions will be made to some important cities and places of interest in India; in this way several provinces will be able to take part in the proceedings. The official languages of the congress will be English, French, and German. An exhibition of various manifestations of tropical disease is being prepared. Scientific papers from medical practitioners are invited; the titles should be sent as soon as possible to the general organizing secretary, Lieut.-Colonel J. Cunningham, I.M.S., at the Pasteur Institute of India, Kasauli, Punjab. It is requested that typewritten abstracts, not exceeding 1,000 words, may be supplied not later than the end of July, and that complete papers shall reach the secretary at least eight weeks before the beginning of the congress. Arrangements will be made to exhibit lantern slides and microscopic preparations. The fee for membership is £2.

FIELD-MARSHAL VISCOUNT ALLENBY will distribute the prizes at St. Mary's Hospital Medical School on Wednesday, June 8th, at 3 o'clock.

THE fourth annual congress of the Incorporated Association of Hospital Officers will commence at the Royal Horticultural Hall, Vincent Square, Westminster, S.W., on Friday, May 27th. The morning session opens at 10.30 a.m., and the afternoon session at 2 p.m. The chief subjects for discussion will be hospital policy with reference to the raising of funds and hospital planning and construction. The annual dinner will take place at the Hotel Cecil in the evening. Visits will be paid to London hospitals and other places of interest on Saturday, May 28th. A hospitals and institutions exhibition in connexion with the conference will be opened by Princess Arthur of Connaught on May 26th at noon, and will remain open on the two following days from noon till 8 p.m.

BY invitation of Mr. Henry S. Wellcome the meeting of the Royal Anthropological Institute on May 24th will be a conversazione to be held at the Wellcome Historical Medical Museum, 54A, Wigmore Street, W., when Professor G. Elliot Smith, F.R.S., will give a brief discourse on the medical and magical aspects of the anthropological material in the museum, and Fellows will have an opportunity to inspect the collections.

AN address on Lord Lister and the romance of surgery will be given at University College by Mr. Raymond Johnson, F.R.C.S., consulting surgeon to University College Hospital, on Monday, May 23rd, at 5.30 p.m.

DR. J. STRICKLAND GOODALL will deliver the St. Cyres lecture at the National Hospital for Diseases of the Heart on Tuesday, May 31st, at 5 p.m. The subject of the lecture will be some general aspects of myocarditis. Tickets of admission can be obtained on application to the Secretary of the Hospital, Westmoreland Street, W.1.

THE annual meeting of the Lebanon Hospital for Mental Diseases was held on May 19th, at 3 p.m., at Friends' House, Euston Road, N.W.1. Dr. H. Watson Smith, director of the hospital, presented his report for the year. This hospital is situated at Asfuriyeh, near Beyrout, in Syria; it was founded in 1900 as an acute mental hospital for the peoples of Syria and Palestine. It is controlled by committees in London, Holland, Switzerland, and Philadelphia.

IN aid of King Edward's Hospital Fund for London the president of the Royal Astronomical Society (Rev. T. E. R. Phillips) will give a lantern lecture at the Polytechnic, Regent Street, London, on Friday, May 27th, at 8 p.m., on the total eclipse of the sun, which traverses part of northern England and Wales on June 29th. The charge for admission is 1s. 6d., but reserved seats can be obtained from the secretary of the Fund, 7, Walbrook, E.C.4, price 4s.

AT a meeting of the Society of Superintendents of Tuberculosis Institutions to be held at St. Thomas's Hospital to-day, Saturday, May 21st, at 2.30 p.m., Dr. G. T. Hebert will read a paper on interpretation of negatives in chest radiology.

THE annual dinner of the Harveian Society of London will be held at the Connaught Rooms, Great Queen Street, on Thursday, June 9th, at 7.30 p.m. Particulars may be obtained from the Honorary Secretary, 81, Cambridge Terrace, W.2.

THE Fellowship of Medicine announces that demonstrations will be given by Mr. J. Swift Joly at St. Peter's Hospital on May 25th, at 2 p.m., and on the same date by Mr. H. Neame, at the Royal London Ophthalmic Hospital, at 1 p.m. On May 26th, at 2.15 p.m., Dr. E. G. B. Calvert will give a clinical demonstration at the Royal Northern Hospital. These demonstrations are free to medical practitioners. From June 8th to 21st the Chelsea Hospital for Women staff

will undertake a special course in gynaecology, including operations, lectures, and demonstrations. A four weeks' afternoon course will be held at the Central London Ophthalmic Hospital from June 8th to July 2nd, and an operative course will be arranged if desired. From June 13th to 25th a course in diseases of children will be given at the Children's Clinic. Sessions will also be held at the Hospital for Diseases of the Heart, Bethlem Royal Hospital, Royal National Orthopaedic Hospital, the Royal Waterloo Hospital, and elsewhere. There will be an afternoon course in dermatology at the Hospital for Diseases of the Skin, Blackfriars, from June 20th to July 1st; on each Tuesday special cases of interest will be shown. From June 27th to July 9th the Victoria Park Hospital will provide a special course. The Fellowship of Medicine can arrange for practical courses in anaesthetics and obstetrics, and for clinical assistantships in gynaecology. The Fellowship provides also a general course of instruction at the associated hospitals. Copies of all syllabuses and of the *Post-Graduate Medical Journal* are obtainable from the Secretary of the Fellowship, 1, Wimpole Street, W.1.

THE Dawson centenary gold medal for original medical research in British Guiana during the triennial period 1923-26 has been awarded to Dr. Basil Noel Victor Bailey for a thesis entitled "Some preliminary notes on Bright's disease in British Guiana."

AT a recent meeting of the Section of the History of Medicine of the Royal Society of Medicine (*Proceedings*, March, 1927, p. 587) the President, Mr. W. G. Spencer, exhibited eighteen letters written by Edward Jenner to Alexander Marcet, physician to Guy's Hospital and one of the founders of the Medical and Chirurgical Society; they were presented to the library of the Royal Society of Medicine by Marcet's great-grandson, Dr. William Pasteur. Mr. Spencer said that the letters have an important bearing on Jenner's statements concerning the pox of domestic animals (cow, horse, and pig) and human small-pox, which have been confirmed by recent observers.

THE report presented to the annual meeting of the Hospital Saturday Fund for London on May 11th showed that notwithstanding the conditions prevailing in the industrial world throughout the greater part of last year the work of the fund was well maintained. The income of the general fund was £79,192, of which £77,037 was derived from collections and donations. In spite of the general strike, which had affected collections in business houses, workshops, and factories, the old position had been nearly regained at the end of the year. In an address on the institutional treatment of the sick, Sir H. Kingsley Wood, Parliamentary Secretary to the Ministry of Health, said that the Government was heartily in favour of maintaining the present voluntary system and was opposed to a State Medical Service. The voluntary system was regarded as one of the best features of the present health system. A striking example of the way in which the working classes had rallied to the support of the voluntary hospital system was shown in the provinces, where the contributions had increased from £841,000 in 1920 to £1,341,000 in 1925. The demand for surgical treatment in hospital had grown tremendously.

THE Duke of Northumberland, as president of the Royal Institution, has nominated the following members of the medical profession as vice-presidents for the ensuing year: Sir James Crichton-Browne, Dr. J. Mitchell Bruce, Sir Almroth Wright, and Sir Arthur Keith.

UNDER an arrangement made between the Metropolitan Asylums Board and the London County Council beds are now available at Queen Mary's Hospital, Carshalton, and Highwood Hospital, Brentwood, for the accommodation of children under 16 years of age suffering from acute rheumatic fever, subacute rheumatism, the later stages of acute rheumatism, rheumatic chorea, and rheumatic carditis, including recurrent attacks. Medical practitioners who desire to recommend patients for admission should communicate with the School Medical Officer, County Hall, S.E.1, giving particulars of the cases. The children must be resident in the county of London.

THE proceedings of the Section of Physics of the first International Congress of Radiology held in London in 1925 are published in the April issue of the *British Journal of Radiology* (Röntgen Society section). Copies, price 15s. net, postage 6d., can be obtained from Mr. Geoffrey Pearce, hon. treasurer, Röntgen Society, 33, Newton Street, London, W.C.2.

THE new number (vol. v, No. 1) of the *Journal of Helminthology*, published by the Institute of Agricultural Parasitology, of the London School of Hygiene and Tropical Medicine, is adorned by the reproduction of a photograph of a group of research workers in helminthology, taken last December; in the centre is Professor Leiper, F.R.S., who is the editor of the *Journal*. The first and last papers in this issue is on three new genera and some of the nematode family, *Protostrongyl* Dr. T. W. M. Cameron. There is also Birks, lecturer in zoology at the Agri Kent, on some helminths parasitic o South-Eastern England. The supplei now reached its third number and af of the diligence with which the depa very special study.

THE International Labour Office ha pamphlets (Nos. 64 to 68) dealing wi (occupational affections); woollen ma powder—chloride of lime; carbon dioxi and coal miners' diseases. They may London correspondent of the Internatic Victoria Street, S.W.1.

QUERIES AND ANS

INCOME TAX.

"D. F. S." ... *pense* ... coun an appoin ... use o private purposes also, and finds that the paying registration, garage, and insura l ttle for running costs and depreciat deduction for income tax purposes?

*** He will have to show that th incurred wholly, exclusively, and neces of the duties of his office; in substanc proof that the council mileage allowa frankly we feel that his success in that is not entitled to charge the whole of professional, as distinct from private,

Liability to British Tax.

"J. M. J.," who is at present practising in the Far East, inquires whether a ship surgeon, whose wife and children live in the Channel Islands, would be liable for British income tax when serving in a British-owned shipping line.

*** He would be liable to tax—less the usual personal and other allowances—in respect of his salary and any other monetary earnings, but not in respect of income not arising from British sources.

Motor Car Allowance.

"MYLAW" inquires with regard to a car which he bought in 1925 and still owns. He has been advised that he can claim depreciation allowance while he retains it and the "obsolescence allowance" when he sells it. He has approached the local inspector of taxes accordingly, and has been informed that he "can claim either depreciation or the cost of renewals, but not both."

*** The inspector's statement is correct, but it does not cover the *obsolescence* allowance, which is a specific statutory allowance somewhat similar in effect to, but distinct from, the "cost of renewal" deduction. If "Mylaw" did not make it clear in his discussion with the inspector that it was the obsolescence allowance to which he referred it might be advisable to do so, and in either case to request him to make it clear whether his letter (quoted above) is intended to apply to both forms of allowance. If the inspector affirms that the depreciation allowance will exclude in due course the obsolescence allowance, we suggest that our correspondent should definitely claim the depreciation allowance. He might write to the Secretary, Inland Revenue, Somerset House, W.C.2, forwarding the correspondence and asking for a ruling.

LETTERS, NOTES, ETC.

SUMMER ON THE RIVIERA.

WINTER visitors to the Riviera are beginning to realize the mistake they make in rushing away from sunny southern France at the end of March. From April until the first days of July the heat is light, dry, and airy, fanned by breezes that sea and mountain interchange. To many the temperature, far from being unbearable, is pleasant, and from July to September there comes a settled spell of cloudless summer: unfailing sunshine and a pure blue sky. The supreme wealth of the Riviera lies in the sun, and it is this wonderful source of healing which has been invoked since the beginning of history. Taking Nice as a standard of the Riviera resorts, the following table of average temperatures (shade) may help to an understanding:

	Deg. F.		Deg. F.
May	61	August	73
June	68	September...	67
July	72		

An excellent service of "auto-cars" is run by the P.L.M. railway company from May to the end of September along the Maures and Estérel coasts from Marseilles to Nice. These services were inaugurated about two summers ago and proved an instant success. Further particulars about summer on the French Riviera can be obtained from the Federation of the Health Resorts of France, 19A, Tavistock Square, London, W.C.1, but the following suggestions as to places to stay at may be of use:

Le Lavandou (Var), between Hyères and St. Raphael, is a picturesque little fishing village with a fine sandy beach, situated opposite the islands of Port Cros and Le Levant. Hotels: Grand Hôtel de la Méditerranée, Hôtel d'Aiguebelle.

Le Canadel (Var), about seven miles to the east of Le Lavandou, a flower-growing centre; good sands; pine trees. Hotel: Grand Hôtel du Canadel.

Cavalaire-la-Croix (Var).—Beautifully situated in the bay of Cavalaire; splendid beach of fine sand sheltered by a marvellous pine-tree forest. A popular all-the-year-round resort. Hotels: Grand Hôtel; Hôtel de la Plage et des Bains.

Juan-les-Pins (A.M.)—One of the most attractive of the summer resorts, nestling among richly scented pines. It possesses a fine sandy beach and is extremely popular on account of its bathing facilities. Hotels: Grand Hôtel; Hôtel de l'Amirauté; Hôtel Windsor; Hôtel de la Pinède.

EARLY PARENTHOOD.

DR. W. W. FORSYTH (Darlington) writes: Letters like that by Dr. Gemmell (JOURNAL, May 7th, p. 862) make one wonder how an unsuspected pregnancy can tuck itself away when the average gossip will spot a five or six months' pregnancy with some certainty in "legitimate" cases. I was, however, called last year to a married woman of average mental acumen whom I had confined twice before. On arrival the pains she had complained of had subsided, the reason crying lustily in the bed, and the look of astonishment on the fac[illegible] amusing almost, neither of t[illegible] The comparative *mildness* [illegible] suspected labours makes one realize how great is the psychical element in labour. My own record for early parenthood occurred in a girl of 13, whose baby weighed 13 *lb. less a few ounces*, but then she had the outward frame of a buxom 20. The father was "unknown."

FOREIGN BODY IN RECTUM.

DR. D. OWEN WILLIAMS (Glandyfi) writes: The notes on foreign bodies in the rectum recall to my mind the case of a man who came to see me some years ago complaining of intense pain in the rectum. Upon examination I removed a circular bone over half an inch in length and about half an inch in diameter; one end was smooth, the other rather jagged; it was hollow in the centre, with a small part of one side removed, making a depression into the hollow. The bone seemed to be part of a mutton bone. After its removal he was at once relieved, and nothing further happened. It had been swallowed, probably in broth or stew.

HERPES AND VARICELLA.

DR. R. LYNN HEARD (Bexley, Kent) writes: In the JOURNAL of May 7th (p. 862) "G. B. P." suggests that the connexion between herpes zoster and varicella is still non-proven. If he will refer to my note of January 15th (p. 124) he will find that on different occasions when attending herpes zoster, with a susceptible child in the same house, I have prophesied that in a fortnight or so the child would develop chicken-pox, which forecast has been verified. He will also find under "chicken-pox" in Price's *Medicine* testimony to the same effect. In one instance a child, about 2 years old, developed chicken-pox, having been infected by its grandfather, who had had a severe attack of herpes zoster, contracted as the result of his visiting a friend similarly affected. For further example I would mention a case where a girl returned home from a visit to North Wales with well developed chicken-pox. She and her mother had been on holiday and had mixed with very few people. It was a puzzle to know where the infection arose until the mother said that she also had had some spots a couple of weeks previously. On examination the remains of a typical herpetic patch were found near the angle of the right scapula, which cleared the matter up at once. It was Dr. W. P. Le Feuvre, of Knysna, Cape Province, who, many years ago, called my attention to the connexion between the two diseases, and the recognition of this and of the *infectiousness* of herpes zoster has solved for me a number of problems.

NERVOUS INFLUENCES ON ENDOCRINE SECRETION.

DR. H. CLULOW NIXON (Bath) writes: A well developed Jewess, aged 28, married about three years, presented diffuse brawny induration amounting to a condition not far removed from stony hardness of the whole of the subcutaneous tissues of both upper and lower limbs. *X*-ray examination, including that of the sella turcica, revealed no abnormality. She had been sent to hospital as a case of "fibrositis" and during her stay she had steam baths and massage. Thyroid and pituitary gland extracts were given regularly. In six weeks a slight change for the better was recorded. She informed me that ever since marriage preventives to conception had been used, for financial reasons. I advised her to refrain from the further use of contraceptives, and in a letter that I received from her recently she states that a healthy boy was born a few months ago; that during her pregnancy improvement began; that the swelling in the legs disappeared, so that now they are much softer; and that the condition of the arms has much improved, but that some induration remains. The patient did not belong to the myxoedemic type, being both quick-witted and intelligent.

EPIDEMIC FURUNCULOSIS.

DR. CECIL E. REYNOLDS (*Los Angeles*) writes: I was much interested in the letter from "R. F." (Scotland) in your issue of January 1st (p. 46), referring to an epidemic of boils and carbuncles. Los Angeles passed through a small epidemic of these affections during October, November, and December, 1926. Five of my personal friends were affected; one, a man of 60, died. I developed four deep carbuncles in succession upon the face—the first local infection of any kind since the age of 14 years. I had no glycosuria, and have quite recovered. Dr. A. B. Cooke, who operated upon me, has remarked the sudden influx of carbuncles in his large general practice during these months of this past year, with some deaths. Casual inquiry has elicited similar observations from other surgeons. I have no theory as to cause; we have had one of the wettest and coldest seasons here that I have experienced in the past fifteen years. I may add that I do not drink city water, but spring water, and the stools are normal and free from parasites.

BENCE-JONES PROTEINURIA: CORRECTION.

DR. BEWLEY, whose name, we regret, was wrongly printed as "Bowley" (JOURNAL, May 7th, p. 838), points out that he is incorrectly reported (col. 2, lines 4 to 6) as saying that "if the precipitate was watched, it would be seen that it came down very rapidly, much sooner than albumin or globulin would be expected to come down . . ." What he actually stated was *that* "the precipitate is often slow in forming and may not *appear for* several seconds or longer."

VACANCIES.

NOTIFICATIONS of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals, will be found at pages 45, 48, and 49 of our advertisement columns, and advertisements as to partnerships, assistantships, and locumtenencies at pages 46 and 47.

A short summary of vacant posts notified in the advertisement columns appears in the *Supplement* at page *211*.

Remarks ON LOOSE BODIES IN JOINTS.*

BY

HARRY PLATT, M.S.LOND., F.R.C.S.ENG.,

SENIOR HONORARY SURGEON AND SURGEON IN CHARGE, ORTHOPAEDIC SERVICE, ANCOATS HOSPITAL, MANCHESTER; CLINICAL LECTURER IN ORTHOPAEDICS, UNIVERSITY OF MANCHESTER.

IT is reasonable to believe that loose bodies in joints must have been familiar to the ancients, for from time immemorial the limbs of man have been subject to injuries of unchanging type. But there is no record of an attempt to remove a loose body by operation until we reach the Middle Ages, when the incomparable Ambroise Paré[1] (1558) extracted a typical specimen from a cystic swelling which communicated with the knee-joint.

In more modern times considerable attention has been directed towards the elucidation of the pathogenesis of loose bodies, and the subject is now endowed with a literature of formidable proportions. A brief review of this historical phase will serve as an introduction to this communication, which will deal more especially with certain practical aspects relating to the diagnosis and operative treatment of loose bodies in the knee-joint.

In 1875 Volkmann[2] presented a broad classification in which loose bodies were divided into two main groups; this is still in use. Group I included the bodies found in diseased joints, and Group II those found in otherwise healthy joints. The distinction between the two is in some respects artificial, but the outstanding contrast is emphasized in proper perspective.

A third group, which does not entirely conform to the requirements of the classical schema, is sometimes recognized. In this are included the loose bodies which develop primarily as synovial chondromata, a process which is little understood, but which merits recognition as a pathological entity.

PATHOGENESIS.

Group I.—Diseased Joints.

There is no mystery in the origin of the loose bodies which make their appearance in joints which are frankly diseased. They result simply from the separation of small portions of the changed articular surfaces. Thus, in osteo-arthritis, marginal osteophytes may sometimes become detached, either spontaneously or after a trivial injury. We must recognize, however, that in a certain proportion of joints which show comparatively mild osteo-arthritic changes accompanied by one or more loose bodies the arthritis is really a secondary development. On the whole, in osteo-arthritis loose-body formation is not very common. In neuropathic arthritis—for example, the familiar Charcot's joint of tabes—the somewhat bizarre hypertrophic and degenerative changes offer an ideal background for the wholesale exfoliation of articular fragments. Under such conditions loose bodies are usually of minor pathological and surgical importance.

In this group of diseased joints the majority of the patients are past middle age, and the loose bodies are almost invariably multiple.

Group II.—Otherwise Healthy Joints.

The pathogenesis of the bodies which form in joints apparently sound to ordinary clinical tests cannot be expounded in so simple a fashion. The essential clinical features have long been defined, the more important being: (1) the comparative youth of the patients (15 to 25 being the age of choice); (2) the high incidence in the male sex; (3) the predilection for the knee-joint—with the exception of the elbow, loose bodies are extremely rare in other joints; (4) the bodies are more commonly single than multiple.

It was obvious to the earliest observers that this type of loose body also was derived from the articular surface (Monro, 1762[3]), and when the patient gave a history of antecedent trauma the method of production seemed to be clear. But when, as not infrequently happened, no record of injury a different explanation was den

Among the first to suggest an alternative hypot Sir James Paget.[4] In 1870 he removed a loose b the knee-joint of a Harrow schoolboy. Histolo amination of the specimen showed that it had been from one of the femoral condyles. In the origi body Paget saw yet another example of a process he had coined the term "quiet necrosis." In a trivial unnoticed injury had produced on the surface a limited zone of necrosis. In due cours laginous flake had become separated, and afte had assumed the typical round, smooth appearan mature loose body. It was not until 1888 that introduced the term "osteochondritis dissec describe the exfoliation of fragments from the surfaces of the knee-joint. But Koenig himself accept trauma as the first stage in the sequence which culminated in the development of such loose

In the later work of the German school there an attempt to extend Koenig's thesis by prov explanation of quiet exfoliation without invokin as a necessary preliminary. Considerable emp been laid on the observation that osteochondritis has a favourite site in the knee-joint. This is a small area on the lateral aspect of the mesial femoral condyle, just in front of the attachment of the posterior crucial ligament (Fig. 1). The area is supplied by a special vessel—the arteria genu media—which in the injection experiments of Ludloff[6] appeared to be an end artery. The position of this vessel at once suggested its vulnerability, and it was concluded that thrombosis might easily be produced, either by injury or after the lodgement of a tiny embolus. In this way a zone of "quiet necrosis" would be determined. Unfortunately for the further exposition of such a thesis, the more recent injection experiments of Nüssbaum[7] show that the arteria genu media anastomoses freely with the vascular surrounding areas.

FIG. of knee- ing vul on inter supplie genu m

Axhausen[5] (1920) has also supported the quie theory from the experimental side. In his c the first stage in loose-body formation is the of a small embolic infarct, which includes a wed area of subchondral bone. Later the infarct bec off from the living bone by the ingrowth of g tissue. Detachment does not occur for some li but finally the fragment is extruded into the jo and enters on its career as an independent lo But Phemister[9] has obtained very different res the experimental production of localized foci necrosis on joint surfaces, for he finds that th areas are not exfoliated. In spite of much evidence at the present time it is generally ag trauma plays a dominant part in the producti ordinary loose body in the so-called normal joint knee-joint a considerable area of both femoral is repeatedly exposed to the risk of direct impa is conceivable that a localized infraction of surface may be induced by comparatively trivial Such an injury may be followed by complete h on the other hand, by an immediate, or delaye tion of an articular fragment. It is also prob traction exerted through the medium of the crucial ligament may tear off a flake in the int region. Freiberg[10] believes that an unusually lon tubercle of the tibial spine may impinge on th ligament when the knee is flexed and externally It has also been suggested that the tibial spine come into contact with the mesial condyle and as the prime detaching force (Roessner[11]).

Although attention has been focused on the intercondylar region, it must be realized that a co proportion of loose bodies in the knee do not from this site. Indeed, it is probable that the represent detachments from other parts of the

[3

* A paper read before a conjoint meeting of the Manchester and Liverpool Medical Societies at the Liverpool Medical Institution.

surface. Patches of early erosion are not infrequently seen in exploratory operations on the knee for the removal of injured semilunar cartilages.

Group III. Synovial Chondromata.

As long ago as 1834 Benjamin Brodie[12] surmised that certain types of loose body originated in the synovial membrane. These are now separately classified under the term "synovial chondromata," and are believed to develop from small nests of cartilage cells commonly found in normal synovial villi. Little is known of the conditions which determine such a change, but it is probable that the bodies are actual tumours. Although small isolated synovial chondromata may be found in osteo-arthritic joints, or in joints presumed to be healthy, the loose bodies which fall into this group are generally present in considerable profusion. Where the synovial membrane is invaded widely, the condition has been termed "osteo-chondromatosis" (Henderson[13]). Many of the synovial chondromata remain attached for an indefinite period, the number of free loose bodies being small.

Changes in Loose Bodies during and after Separation.

It is well recognized that, irrespective of their mode of origin, many loose bodies do not become completely detached for some considerable time. During this intermediate stage both the cartilaginous and bone elements undergo changes which are characteristic of living tissue; but after the body has broken away from its vascular pedicle the bone cells die. The cartilage cells, however, continue to live and proliferate, nourished by the joint fluid (Fisher[14]). The original hyaline cartilage may be replaced by fibro-cartilage (Phemister, loc. cit.). After a sojourn in the joint cavity the loose bodies tend to increase in size and take on a uniform shape and appearance.

A loose body may acquire a secondary attachment to the synovial membrane, and so for a time its migratory habits are suspended. In somewhat similar fashion a group of bodies may accumulate in a pocket which ultimately becomes shut off from the joint cavity proper. An occasional hiding place for a solitary body in the knee-joint is a pouch connected with the coronary attachment of the semilunar cartilages.

LOOSE BODIES IN THE KNEE-JOINT.

A full description of the symptomatology of loose bodies in the knee-joint lies outside the scope of this paper. It is sufficient to state quite broadly that the clinical picture is embodied in the familiar syndrome of "internal derangement" of this joint. In the so-called normal knee this syndrome is usually presented in clear-cut fashion; in a diseased joint other long-standing symptoms may obscure the signs which the loose bodies themselves evoke.

There are, of course, many points of clinical interest which distinguish loose bodies from other more common causes of internal derangement—for example, injuries of the semilunar cartilages. Where the loose body has been actually palpated the problem is solved; but in the majority of instances the differential diagnosis must rest on the radiographic findings.

Once the presence of a loose body has been established, apart from certain reservations as to age, economic circumstances, and the existence of advanced joint disease, operative removal is indicated. But before the knee-joint is opened the surgeon should be in possession of information which enables him to define both the exact number of loose bodies and their distribution in the joint cavity. This means that as a routine the knee should be radiographed from many angles, and in the position of flexion as well as extension. In addition, stereoscopic views are often invaluable.

Such requirements raise the important question of the interpretation of the radiographic appearances of loose bodies in various phases of their development.

RADIOGRAPHIC DIAGNOSIS.

1. *The Loose Body before Separation—Osteochondritis Dissecans.*

We have already referred to the stage when the developing loose body is still attached by a pedicle. In certain positions of the joint the fragment lies snugly in its fossa. At other times it flaps about on its hinge, but, although its range of movement is small, it may give rise to the characteristic symptoms of internal derangement. There is a danger that a pedicled fragment, unless temporarily displaced from its bed, may be overlooked in conventional radiograms; but that the radiographic evidence of osteochondritis dissecans may be clear-cut is well exemplified in the following case.

Some four years ago I saw a public school boy, aged 15½, with a typical history of recurring attacks of transitory "locking" of the knee, following a direct contusion sustained at football two years before. The boy's family doctor had felt a loose body on the outer aspect of the knee during two of the attacks, but when I examined the joint it was "silent." The radiograms (Figs. 2 and 3) showed an interesting combination of lesions:

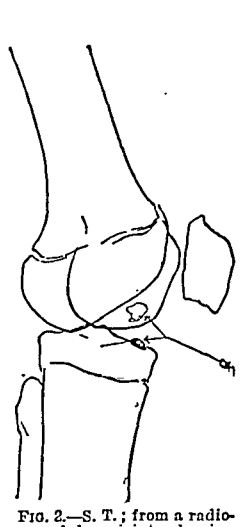

FIG. 2.—S. T.; from a radiogram of knee-joint, showing (*a*) loose body, (*b*) patch of osteochondritis dissecans.

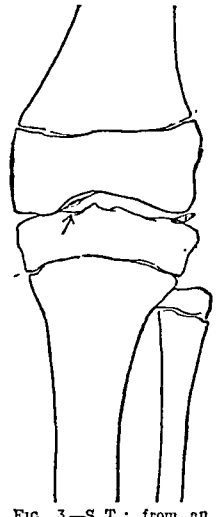

FIG. 3.—S. T.; from an antero-posterior radiogram of knee.

(*a*) a definite loose body lying on the outer head of the tibia; and (*b*) an irregular patch in the intercondylar region at the classical site for osteochondritis dissecans. The appearance here suggested that a plaque of the articular surface was in process of separation.

Removal of the loose body was advocated, but for certain reasons the operation was postponed for a year, during which time further attacks of locking occurred.

When the knee-joint was opened a loose body the size of a threepenny-piece was seen, attached by a slender pedicle just in front of a pit on the lateral surface of the inner condyle. After its removal a search was made for the rounded loose body which had always shown up well in the radiograms. This was discovered lying on the outer head of the tibia, but enclosed in a synovial pocket and obviously incapable of shifting sufficiently to account for the symptoms of locking.

This case is an excellent example of the classical osteochondritis dissecans following a known injury, and with the loose body incompletely detached but already causing symptoms. It is further interesting in that a second loose body, obviously of an older "vintage," was at first assumed to be the sole cause of the derangement, and yet was proved to be incapable of free migration.

2. *The Loose Body Invisible.*

A loose body may also escape recognition after complete detachment. This happens when its lime content is small, and particularly when the faint image is superimposed on the denser shadow of the femoral condyles. But this should be a rare occurrence under the conditions of modern radiographic technique, when the clinical signs have led to a presumptive diagnosis of loose body.

3. *Multiple Bodies.*

It does not seem to be widely recognized that operations for the removal of multiple loose bodies are by no means uncommon. I find in my own clinical material that the incidence is between 40 and 50 per cent. For this reason the pre-operative counting of multiple loose bodies is a

diagnosis. But the body or group of bodies, with reference to the internal anatomy of the knee-joint, is also required.

It will be remembered that the joint cavity is divided into five distinct but intercommunicating compartments—three in front and two behind. These are the *supra-patellar* pouch; the *antero-mesial*, the *antero-lateral*, the *postero-mesial*, and *postero-lateral* compartments. It is important also to realize that each pouch allows of separate exploration through a relatively small capsular incision.

A loose body originating in one of the anterior compartments finds a free passage from one to another, but does not ordinarily make its way into a posterior compartment, as the connecting path is somewhat circuitous. Free communication between the two posterior pouches is, for practical purposes, blocked by a mid-line synovial partition attached in the intercondylar region, so that a loose body originating in either of these pouches tends to have a comparatively small range of excursion.

It is a common experience to find multiple loose bodies distributed in both the anterior and posterior divisions of the knee-joint, and, in the absence of definitive information, it is an easy matter to explore such a joint and to leave one or more bodies behind. Such omissions have been brought forcibly before my notice in my earlier operative experience in this field.

Wherever possible the enumeration and localization of each separate group should be carried out the day before the operation. The joint should never be explored on information several weeks old, as a redistribution of the bodies may occur during the interval. The patient himself is occasionally conscious that the bodies have moved, and it is always wise to question him deliberately on this point.

Exploration of the Knee-joint for the Removal of Loose Bodies.

The removal of a solitary loose body which has been accurately localized is an operation of extreme simplicity. The appropriate pouch is entered through a small capsular incision, which may be little more than a mere stab cut. In such a procedure the joint disturbance is negligible, and full recovery of function is seen within a few weeks.

I hold very strongly that the operative treatment of multiple loose bodies should be based on the same conservative principle. Each pouch should be invaded separately. or this an equal number of short skin incisions may be sed, or alternatively a convenient flap, which provides cess to two or more compartments simultaneously. The st majority of multiple loose bodies can be dealt with in manner with great advantage to the patient and the ure of his knee-joint.

exceptional circumstances it is advisable to display interior of the knee-joint more completely, as in the oval of synovial chondromata when present in large ers. This will naturally be accomplished by one of ecognized types of full arthrotomy, in which the patella her divided in the mid-line or displaced to one side other. It must be remembered that such an exposure an inspection of the three anterior pouches only. sterior compartments must of necessity be approached ely.

aluo of arthrotomy in miniature will be further ted when it is realized that in certain joints, after of multiple loose bodies, a fresh "crop" may at some future date and re-exploration become .

Compartmental Surgery of the Knee.

oval of multiple loose bodies illustrates what may the *compartmental* surgery of the knee-joint. oration of the different pouches there are certain tomical and technical peculiarities to which brief ay now be made.

he Anterior Division of the Knee-joint.

ntero-mesial and antero-lateral pouches are ntered for the removal of injured semilunar erations which are amongst the commonplaces of joint surgery. Identical exposures are used fo extraction of loose bodies. It may be remarked tha typical plaque of osteochondritis dissecans on the condyle, and the flapping, loose body are best seen dealt with from the antero-lateral pouch.

The supra-patellar pouch is inspected through a sl vertical incision in the rectus femoris. The removal o loose body from this pouch via a stab wound is reminisce of the old stylo of operation of the pre-antiseptic era.

2. The Postcrior Division of the Knee-joint.

This is a less familiar hunting ground, as the pouches ar rarely explored except for the extraction of loose bodies.

(*a*) The postero-mesial pouch is exposed after defining the posterior edge of the internal lateral ligament and retracting the sartorius as it skirts the posterior border of the femoral condylo. (Fig. 4.) With the knee flexed to a right angle the pouch bulges prominently, and when opened by a vertical cut shows a capacious interior. Access to the postero-lateral compartment is barred by the median partition already described.

Bodies which occupy the posterior compartments often tend to disappear into the intercondylar region, and are occasionally most difficult to find. When present in considerable numbers, small groups may become encysted in synovial "nests," which must be opened before the bodies can be extracted. Illumination of the interior of the pouch by means of a head lamp is useful, if the search tends to become prolonged. If the number removed does not correspond to the pre-operative count, it is a wise precaution to syringe out the pouch with saline under considerable pressure. An elusive body may then float into view. This manœuvre is, of course, applicable to all pouches. Movements of the knee, and particularly rotation of the tibia on the femur, sometimes helps to dislodge a concealed body.

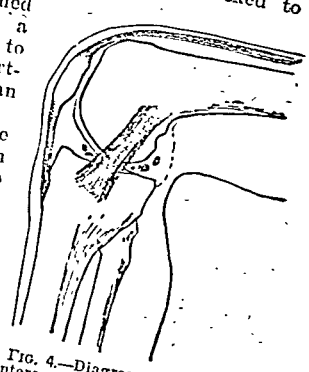

Fig. 4.—Diagrammatic view of antero-mesial and postero-mesial pouches with loose bodies *in situ*.

(*b*) The postero-lateral pouch is opened behind the external lateral ligament, and the same principles are again illustrated.

(*c*) *Poplitcal Approach.*—There is an alternative method of approach to the posterior division of the knee-joint which was advocated some years ago by Brackett and Osgood. In this a mid-line incision is made over the popliteal nerve and popliteal vessels the joint capsule is opened. Either pouch may be opened separately or the intercondylar fossa is readily displayed. Where there is a temporary encystment of a group of loose bodies in a pocket connected with the median partition the popliteal approach offers many advantages.

Conclusions.

1. When the symptoms of internal derangement of the knee suggest the presence of a loose body, a systematic radiological examination is essential. This should be carried out with a view to the possible demonstration of (*a*) an area of osteochondritis dissecans; (*b*) a loose body in process of detachment; or (*c*) one or more loose bodies free in the joint cavity.

2. When a *single* loose body is demonstrable the existence of additional bodies should always be suspected.

3. *Multiple* loose bodies demanding removal are common. Before operation is undertaken they should be accurately counted and their exact location defined with reference to the various joint compartments. This information should be obtained during the few days immediately preceding the operation.

4. Given an accurate pre-operative diagnosis, the removal of multiple loose bodies through an extensive arthrotomy is rarely necessary. The bodies should be extracted in turn from the various pouches, which are entered by means of short capsular incisions. With such a technique there is a

minimum interference with the knee-joint, and rapid return of function is favoured. (Arthrotomy in miniature.)

5. A *complete arthrotomy* should be reserved for knee-joints in which loose bodies occur in considerable profusion in the three anterior pouches.

An Address ON THE TREATMENT OF OBSTRUCTIVE LESIONS OF THE COLON.*

BY

J. P. LOCKHART-MUMMERY, F.R.C.S.,

SENIOR SURGEON, ST. MARK'S HOSPITAL, LONDON.

TWENTY years ago chronic obstructive lesions of the colon were rarely, if ever, diagnosed, except as the result of an operation for acute obstruction or a *post-mortem* examination. At the present day the majority—I would almost like to say the great majority—of such lesions are diagnosed and treated before the onset of acute symptoms. Statistics on such a subject are difficult to obtain, but a paper recently published by Burgess of Manchester contains figures which illustrate this point.[1] Out of 485 cases of cancer of the colon admitted between the years 1913 and 1922 to the Manchester Infirmary 173 had acute obstruction—that is, 64.4 per cent. were diagnosed before acute obstruction had occurred. I know from my own experience that each year I see more cases where the diagnosis is made or suspected in time to prevent the onset of acute symptoms.

The results of operations for obstructive lesions of the colon twenty years ago were very bad. The mortality was high and the recoveries were for the most part accompanied by a permanent faecal fistula of some kind. As the result mainly of improved diagnosis all this has been changed, and there are now few serious conditions which show better results from skilled surgery.

The fact that the surgeon is now able to operate upon lesions of the colon before the onset of obstruction has entirely altered the type of operation performed for this condition, and with proper precautions and careful technique it is now possible to resect that portion of the colon containing the lesion and to join the bowel up by axial union in one operation with very little risk—a procedure which was almost unheard of twenty years ago, when Paul's two-stage method, Senn's plates, Robson's bobbin, or Murphy's button were in use.

I do not propose to describe in detail the symptoms of obstructive lesions of the colon, but only to say that in my experience the most important early symptom is repeated irregularity of the bowel actions without adequate cause, more particularly repeated attacks of slight diarrhoea alternating with constipation and vague abdominal discomfort. We have a number of methods to help us in making a diagnosis, but it is as well to own that none of them are very reliable. The presence of occult blood in the stools on microscopical examination is valuable in cases of cancer, but cannot be relied upon, and is of no negative value.

X-ray examinations after a barium enema are very useful, but must be very well done with a first-rate apparatus having a very short exposure so as to eliminate movement of the bowel and ensure a sharp edge to the shadows. Also the examination must be repeated to avoid as far as possible accidental appearances. The appearances of a well marked filling defect in one part of the colon if the examination is repeated some days later affords valuable evidence, more particularly if belladonna has been administered to eliminate spasm. It is not, however, entirely reliable, and the absence of a filling defect will not exclude a lesion. Lesions due to diverticulitis can now be diagnosed with considerable accuracy by the *x* rays and a barium enema, but very good photographs are necessary.

A sigmoidoscopic examination is very useful, and such evidence as it affords is reliable. It does not, of course, enable a growth above the middle of the pelvic colon to be seen, but it at least has this advantage—that the absence of a lesion up to this level tells the surgeon that any lesion present will be sufficiently high up to allow of resection from the abdomen, or short-circuiting by lateral anastomosis, and that colostomy can be avoided.

Too often it happens that with all our efforts we cannot arrive at an exact diagnosis, although there remains a grave suspicion that a lesion in the colon is present. In such circumstances we should not hesitate to back our opinion and advise an exploratory laparotomy. The "wait and see" policy generally results in disaster. The risks of exploratory laparotomy are very slight, while the danger of leaving a carcinoma of the colon is very grave, more especially as the results of partial colectomy for cancer of the colon are better at an early stage than those for removal of cancer in any other part of the body. Restoration of function is usually perfect and the tendency to recurrence after removal of a cancer in the colon is very slight compared with cancer elsewhere.

The majority of obstructive lesions in the colon are the result of cancer, but there are a number of other conditions which also cause such symptoms. One, which of recent years has come into considerable prominence, not because it is rare, but because it had not hitherto been recognized, is diverticulitis. This curious condition causes a tumour very similar to a malignant growth and partial obstruction of the bowel lumen, often quite suddenly, as the result of acute inflammation in, or around, the diverticula. The distinction between diverticulitis and cancer is not always easy, but the facts that the former is accompanied by signs of inflammation, while the latter is not, and that bleeding is rare in cases of diverticulitis, while it is the rule in cases of cancer, help considerably in forming a diagnosis. An *x*-ray examination after a barium enema will generally give well marked evidence of diverticulitis; but, of course, the presence of diverticula in the bowel does not necessarily exclude the presence of a growth also, as the two conditions are often associated.

Of recent years it has proved possible to resect completely a portion of the large bowel badly damaged by diverticulitis and restore the bowel by axial union.

Hyperplastic tubercle is a rare disease which gives rise to stricture and tumour in the colon and closely simulates diverticulitis. It can be completely cured by resection of the affected portion of the bowel. Bands and adhesions are, of course, frequently met with, involving the colon and causing obstructive symptoms. They are difficult to diagnose, but very easy to treat once they are detected.

Chronic volvulus is a rare condition, which is occasionally diagnosed as the result of an *x*-ray examination. Quite recently I was able to make this diagnosis in a middle-aged lady who had repeated attacks of obstruction, which came on quite suddenly with great pain and distension. The attacks had gone on for a number of years, but were getting more severe and less easily amenable to treatment. At operation a very large volvulus of the sigmoid was found, which was exactly as seen in the *x*-ray photographs; I resected the whole loop and performed an end-to-end junction with complete success

The patients suffering from obstructive lesions of the colon are usually elderly, and this adds an element of risk. Fortunately with proper care we are now able to operate on quite elderly people with little more risk than would be the case with younger patients, providing certain precautions are taken, but these precautions must be very carefully observed.

I attach great importance to very careful preparation of the patient. At least a week should be devoted to this.

*A paper read before the Nottingham Medico-Chirurgical Society, March, 1927.

The bowels should be well cleared (with castor oil for preference), and then kept moving easily with petroleum and drachm doses of castor oil. On no account should the patient be operated upon till several days have elapsed after the necessary preparation, and those days should be spent in bed so as to rest the heart and allow the patient to build up a reserve of energy. This preparatory treatment often causes the patient annoyance, as he fails to see the necessity for it; but I am convinced of its advantages. Small doses of strychnine during the week prior to operation are also helpful. Some form of intestinal antiseptic should also be given; of these I favour kerol and Bulgarian lactic acid bacilli to modify the intestinal flora. The hygiene of the mouth should be attended to, and the patient given plenty of water to ensure that the tissues are well washed out and the blood volume good; a dehydrated patient is always a dangerous one to operate upon. In cases of exceptional risk a blood transfusion should be performed some days before operation.

The anaesthetic is of considerable importance, and ether and chloroform as a rule should be avoided as far as possible. I favour a combination of twilight sleep and local or spinal anaesthesia, or gas and oxygen and local anaesthesia. This greatly reduces the risks, as it enables us to avoid making the patient sick or ill, and does not interfere with his nutrition by causing dyspepsia and loss of appetite.

The incision, of course, depends on the situation of the lesion, but when this is known approximately I always prefer a diagonal incision, which gives free access to the colon. It is also the most convenient for local anaesthesia, as it does not involve more than one nerve in the main incision, and this can be readily blocked. It is easily closed, and does not, in my experience, result in hernia. I have used this incision for many years, and consider it vastly superior to any other. It affords the best and easiest access to the parts, and enables the surgeon to work with the minimum of disturbance of the abdominal cavity.

If the lesion, as is usually the case, is on the left side, the patient should be rolled over slightly to the opposite side, with sandbags under the hip and shoulder and a large pillow under the knees. In this position the colon comes easily into the wound and the small bowel falls away and does not interfere with the operator. Should it be necessary to resect the splenic angle, easy access to this part of the colon will be secured by prolonging the incision backwards towards the last rib.

When the bowel can be drawn out of the wound I prefer to make an open resection with the ends of the bowel and mucous membrane exposed, merely controlling the contents with rubber clamps. The ends are sewn together under the surgeon's eye, and it is possible to be sure that a proper blood supply is left at both ends. One of the chief reasons why axial union of the large gut has been considered unsafe is because surgeons have not realized the importance of ensuring a good blood supply to both ends of the bowel. The blood vessels of the large gut are parallel with each other and anastomose comparatively little; as a result, if the bowel is cut directly across, the stitches joining the ends on the mesenteric side are liable to constrict the blood vessels feeding the junction on the side opposite the mesentery, and most of the disasters that have occurred after axial union of the colon, and were often attributed to faulty stitching, have really been due to sloughing from an inadequate blood supply. As I pointed out many years ago, this difficulty can easily be got over by dividing the bowel at an angle of 45 degrees instead of at right angles. This has the advantage of ensuring a good blood supply to the whole of the joined edges, and also compensating for any narrowing of the lumen caused by the stitching. I put in a couple of guide stitches at either side of the bowel ends, and then sew straight across from one side to the other on the mesenteric side, the stitch being continued right round until it reaches the point where it commenced. A second, peritoneal stitch is then inserted, which also closes the gap in the mesentery on the inner side, a slight gap being left on the outer side of the mesentery to drain the

The Splenic Angle.—The diagonal incision already described is very useful here, as it gives excellent exposure of the angle and allows the colon to be easily freed. It is very necessary to free the colon thoroughly to get the ends to come comfortably together. Care has to be taken in freeing the angle itself not to damage the lower part of the spleen, which is in very close contact, or the kidney and pancreas, which are close behind it. Some of the best results I have seen have been in cases of resection of the splenic angle. I removed a carcinoma of the splenic angle in a jockey eleven years ago, and this year he won one of the classical races.

The Pelvic Colon.—This is the commonest situation, and more than half the cases of resection are included in this area of the colon. Much depends upon the part of the pelvic colon involved. If it is in the descending colon, or upper part of the pelvic colon, the resection should not be difficult. Greater difficulty, however, occurs when the lower part of the pelvic colon is involved. In all cases the outer layer of the pelvic mesentery should be divided near its base for a considerable distance and the bowel carefully stripped up so as to free it well from the left iliac fossa. There are no vessels entering the mesentery at the outer aspect, so that free stripping is quite safe, and considerable mobilization of the colon can thus be obtained. The chief difficulty arises with cases of diverticulitis, as there are frequently dense adhesions to other structures, more particularly the bladder in males, and the uterus or left tube in females. It is very important to interfere as little as possible with adhesions in cases of diverticulitis, as serious sepsis may be lighted up. On the other hand, the condition is not malignant, and excision should be carried out when possible, even though parts of other organs have to be sacrificed. I have on several occasions removed the whole uterus and left tube and resected portions of the small gut in order to remove tumours due to diverticulitis. If the bladder is extensively involved excision is, of course, out of the question.

The Lower End of the Pelvic Colon.—For two reasons this is the most difficult situation. The first is that there is often not enough healthy bowel below the tumour to allow of a proper resection, or the bowel is so short that the resection has to take place within the abdominal cavity. The second, and more serious, difficulty is that the blood supply to the upper part of the rectum is liable to be gravely interfered with if a portion of the pelvic colon immediately above has to be removed. The surgeon may be faced with serious difficulty in deciding what he should do. One alternative is to make a complete abdomino-perineal excision, leaving a permanent colostomy of the upper end, and this may be the only procedure possible when the growth is low down in the pelvis, but still excisable. Another alternative is the tube method, which was described by me in 1908; the principle of this is that after removing the tumour a long rubber tube of large calibre is sewn into the upper end of the bowel, and then passed down through the rectum and out of the anus. The tube is then drawn on until the upper bowel is lightly invaginated into the upper end of the rectum and is secured there by a few stitches. This method gives very good results, but it is decidedly dangerous owing to the fact that the blood supply to the rectum cannot be relied upon. If this method has to be used the surgeon must be certain that he is not seriously damaging the blood supply to the rectum, which will depend entirely on the two lower sigmoid arteries. In view of this doubt good drainage should be provided from behind, and a temporary caecostomy or colostomy performed.

The results of colectomy are good both from the point of view of immediate risk and from that of restoration of function. The mortality from operation is about 16 per cent., but this is counting many of the older cases and can certainly be reduced much below this figure. The following table shows the mortality following colectomy (53 cases) and the condition for which the operation was performed.

	Cases.	Deaths.
Cancer	41	7
Diverticulitis	9	2
Chronic volvulus	3	0

There must always be some risk as the patients are not only old, but often in a bad state of health from partial obstruction and dyspepsia over long periods, which cannot be entirely compensated for by the preparatory treatment. Also colectomy carries with it a fairly high risk of post-operative infarct. The risks are not serious when we consider the grave nature of the lesions for which the operation is done.

It is now quite exceptional to have any faecal fistula after partial colectomy. As a rule the wound heals by first intention and the patient is up in under three weeks quite healed. The restoration of function is perfect, as the loss of a few inches of colon causes no inconvenience. When performed for cancer this operation gives the best results of all cancer operations, as there is no mutilation or limitation of normal function, and the tendency to subsequent recurrence is very low.

Notes on JUVENILE RHEUMATISM:

BEING A COMPARISON OF THE REPORTS OF THE BRITISH MEDICAL ASSOCIATION AND THE MEDICAL RESEARCH COUNCIL.

BY

REGINALD MILLER, M.D., F.R.C.P.,

PHYSICIAN, PADDINGTON GREEN CHILDREN'S HOSPITAL; SENIOR PHYSICIAN TO OUT-PATIENTS, ST. MARY'S HOSPITAL, LONDON.

IN July, 1926, there appeared the first report of the British Medical Association Committee of Inquiry into Rheumatic Heart Disease in Children.[1] It dealt with four important aspects of the problem of juvenile rheumatism, of which I am now chiefly concerned with two—namely, the "Environmental and other Predisposing Causes of Rheumatic Infection," and the "Effect of Tonsillectomy on Rheumatic Infection in Children."

In March, 1927, the Medical Research Council published a report[2] on "Social Conditions and Acute Rheumatism," one of a series of "Child Life Investigations." As the title implies, this dealt with some of the same questions as those parts of the B.M.A. Report already mentioned.

It is the purpose of this communication to examine these two reports where they overlap and to compare their results. This has not yet been attempted: the reports made no mention of each other, and indeed were drawn up by entirely different committees and based on investigations undertaken altogether separately from each other. Both sets of investigations were prolonged and widespread, consequently where agreement is found in the two reports there is a considerable weight of evidence in favour of the result reached.

In April, 1927, the B.M.A. Committee issued a second report,[3] with which I am not here directly concerned.

The chief points of contact between the two reports here to be considered are six in number. On four of them it may fairly be claimed that agreement is shown; these relate to the influence of (1) social status, (2) heredity, (3) school environment, and (4) tonsillar disease and tonsillectomy. In the remaining two questions, those of the influence of (5) contagion and (6) damp dwellings, agreement appears to be lacking.

1. *The Influence of Social Status.*

In this matter the B.M.A. Report made two points—namely, that rheumatic infection is far more common in the poorer classes than in the well-to-do; but that, on the other hand, the incidence of the disease was less in the lower than in the upper strata of the poorer classes. With both these views the M.R.C. Report agrees. On the first point Dr. G. F. Still gives valuable figures (p. 7):

"In the Children's Out-patient Department of King's College Hospital, where only children up to 10 years of age are treated, there were, amongst 1,000 consecutive cases, 229 children between 6 and 10 years old: out of these 229 cases, 13.1 per cent. showed

evidence of acute rheumatism (3.5 per cent. joint symptoms and the rest heart affection or chorea). In a private practice dealing almost exclusively with the well-to-do, there were, amongst 700 consecutive cases between the ages of 6 and 10 years, 5 cases of acute rheumatism (2 of joint affection, 2 of endocarditis, and 1 of chorea), so that less than 1 per cent. (0.7 per cent.) showed evidence of rheumatism."

On the second point, the lessened prevalence amongst the poorest children, the M.R.C. Report states (p. 95):

"if the hospital patients are divided into three classes according to the degree of poverty, the poorest of these three, the very poor and destitute, show a lower incidence of rheumatism than the other two."

It may therefore be held to be established that juvenile rheumatism is a disease of the poor, but not particularly of the poorest.

2. *The Influence of Heredity.*

The B.M.A. Report examined the evidence which had been recently published on this point and tended to the conclusion that the influence of heredity on the large-scale production of the disease was less potent than many had been inclined to think. On page 7 the following occurs:

"Figures such as these cannot be ignored, but it is difficult to know precisely what importance to lay upon the hereditary factor. In the first place, rheumatism is a very common disease, and it is concentrated in the families of the poorer classes; thus in any case it is bound to appear frequently in the families of rheumatic children. Again, if strictly environmental causes are of great importance, it must be *remembered that in most instances they* will operate alike on the family and the patient.

"The point at issue is this: Does the hereditary and family tendency swamp the environmental factors at work in producing the disease? Taken at their face value, the figures quoted above might suggest that this is so, but I doubt if they justify a conclusion more definite than that perhaps the hereditary influence aids and abets the environmental influence."

The M.R.C. Report, after sifting its evidence carefully, concludes (p. 95) that "no sufficient evidence of heredity was forthcoming."

It is satisfactory that there is found to be so close an agreement on this matter, which is clearly of great importance in the problem of the prevention of the infection.

3. *The Influence of School Environment.*

The B.M.A. Committee used the term "school environment" in a broad sense, meaning the circumstances of a child living at home and undergoing compulsory education at a day elementary school. It is in this sense that the term is used here. The opinion of the B.M.A. Committee was to the effect that in the production of rheumatism the influence of the child's home was greater than that of its school; but that, on the other hand, attendance at school had an important influence on increasing the severity of the infection in rheumatic children, thus favouring heart disease. The view of the Committee is, perhaps, best summarized in its *second* report (p. 122).

The M.R.C. Report brought forward novel and important evidence on this question by comparing the prevalence of rheumatic infection in day elementary schools with that in Poor Law institutions. The incidence of the disease in the latter was found to be almost abolished.

Four Poor Law institutions, in reality residential schools, were examined. In one the children lived in "barrack" schools housing a large number in each; in the others they lived in houses, or so-called "cottages," housing twelve to fifty children each, living under a "foster-mother." The total number of children in residence was over 1,800. They went out for their education, presumably like the boys of a large public school.

Thus it is seen that this comparison appears to throw the emphasis back again on to the "home" as opposed to the "school" itself, for this evidence points to the conclusion that children taken from the rheumatic stratum of society escaped the disease if transferred to a school which they attended from healthy "home" surroundings.

4. *The Influence of Tonsillar Disease and Tonsillectomy.*

Tonsillar Disease.—In common with the results of previous investigations both reports found a high incidence of diseased tonsils in rheumatic children. The figures reached in both reports were closely similar. The B.M.A. Report (p. 16) found diseased tonsils in 83 per cent. of cases in active stages, and in 73 per cent. of those seen in quiescent stages. The M.R.C. Report (p. 99) gave 75 per cent. as the proportion of rheumatic children showing unhealthy throats, as compared with 55 per cent. in non-rheumatic hospital children. It also made another interesting observation—namely, that in the Poor Law institutions in which the incidence of rheumatism was conspicuously low, the percentage of children showing unhealthy throats was down to 36.5. The agreement here is therefore particularly close.

Tonsillectomy.—The influence of the complete removal of diseased tonsils in rheumatic children was investigated by the B.M.A. Committee, and the conclusion reached (p. 4) was that their inquiry

"suggests that in the child whose tonsils have been completely removed a milder type of rheumatic infection in which the cardiac lesions are relatively light is likely to be seen."

This opinion was based on investigations detailed in Part III of the Report (pp. 16-20), where the attempt was made to establish three propositions: (1) that the clearest estimate of the value of tonsillectomy in juvenile rheumatism was to be obtained, not by a "follow-up" method, but by a study of active rheumatism in tonsillectomized children; (2) that, if this were done, it would be found that in such cases the rheumatism was of a type milder than the ordinary, the heart being conspicuously spared; (3) that the commonest manifestation of any severity in tonsillectomized cases was chorea, and that this tended to be "uncomplicated" by heart disease.

The M.R.C. Report did not directly address itself to the important question of the influence of tonsillectomy, but one set of the figures published in it was so strongly confirmatory of the conclusions referred to above that it must here be mentioned. The Report (p. 40) says:

"It is curious to note the preponderance of attack by chorea over other forms of rheumatic manifestation in those 60 cases whose tonsils had been removed. 66.7 per cent. of those who developed a first attack of rheumatism some time after removal of the tonsils had it in the form of chorea, and of these all but 4 had no other manifestation of the disease."

These figures are noteworthy as they represent the largest series yet published of cases of chorea in tonsillectomized children, and that 40 such cases can be quoted in which no fewer than 36 showed no other manifestation of the infection is an important observation. The comment made in the M.R.C. Report on these figures is merely that they "suggest that removal of the tonsils affords no protection against attack by chorea"; but surely the significant conclusion to be drawn from them is that of the modifying influence of the operation on the severity of the infection.

Thus on the two points of the preponderance of chorea and the comparative absence of carditis in the rheumatism of tonsillectomized children, the M.R.C. Report appears to offer important evidence confirming the conclusions of the first B.M.A. Report.

On the curious frequency of chorea as the manifestation of rheumatic infection in tonsillectomized children, Carey Coombs has recently written[4]:

"Now, chorea is the most easily excited of all the rheumatic phenomena. It takes a smaller dose of infection to upset the brain than it does to inflame the heart or joints, or to call into being a subcutaneous node. Chorea is more often met with as a solitary manifestation of rheumatic infection than any of the others."

Since this was written the figures quoted above have appeared in the M.R.C. Report. It may be hoped that they will help to oust juvenile rheumatism from its proud position of being the only relapsing or chronic infection closely associated with tonsillar disease in which it is thought desirable to retain unhealthy tonsils *in situ*.

5. *The Influence of Contagion.*

Passing to the first of the two subjects on which the two reports fail to confirm each other's results, the possible influence of contagion in spreading the disease has been most seriously considered in the M.R.C. Report. The subject is introduced thus (p. 8):

"The question of most practical importance is whether rheumatism is infectious, and, if so, whether it is carried by persons, by fomites, by dwellings, or in any other preventable way. . . . Most of the statistics and observations contained in this Report are directed especially to the solving of these problems. . . ."

Much space was given, in the Report itself and in three appendices, to the sifting of evidence on this point. The results obtained were summarized on page 98 as follows:

"On the whole, while it cannot be said that there is, in the facts collected, any conclusive evidence of contagion, many of them are consistent with this view."

There was contained in the Report much more argument on the matter than can be quoted here, and the general impression left on the reader's mind is that on the influence of contagion the verdict of the Report was one of "not proven" rather than "not guilty."

On the other hand, the B.M.A. first Report, although specially concerned with the question of the mass-production of the disease, made scant reference to the *possibility of its spread by contagion*. In the Preface, expressing the views of the Committee as a whole, such a possibility remained entirely *unmentioned*. In the section (Part I) devoted to the "Environmental and other Predisposing Causes of Rheumatic Infection," for which I was responsible, the only mention made of this matter was (p. 7):

"All the evidence points against the importance of this factor (*direct contagion*), although everyone has from time to time seen two cases arising synchronously or close together in a family. Probably we should liken rheumatism in this respect to pneumonia or appendicitis rather than to tuberculosis. . . ." (p. 9): "Direct infection from one case to another is of no practical importance."

Should the theory that infection from case to case plays any real part in the production of juvenile rheumatism on a large scale be accepted, the whole of our treatment of the disease will require alteration. It is therefore of great importance that we should not be persuaded to drift into agreement with such a conjecture. For this reason the following considerations which weigh against such a view are submitted here.

(*a*) We have already seen with what purpose the M.R.C. investigations were undertaken, and the negative character of the evidence elicited in the study of cases of rheumatism amongst the poor in their own homes. A further study of the few cases which arose in Poor Law institutions was made, with the result that "no evidence of 'infection' from one case to another could be found in any of the schools visited" (p. 84).

(*b*) The fact that although rheumatism is a disease of the children of the poor it is less common in the poorest than in the stratum above them, shows clearly that overcrowding is not a factor of prime importance in the production of the disease. This peculiar class incidence is admitted in the M.R.C. Report; its significance against the theory of contagion is hardly faced.

(*c*) In hospitals the disease is not seen to spread. This fact of universal experience is not mentioned in the M.R.C. Report, so far as I can ascertain.

(*d*) The theory of possible contagion is apparently attractive to those who are now beginning to study rheumatism from the standpoint of public health; it is important, therefore, to state candidly that there is no such tradition on the side of clinical medicine. The B.M.A. Committee which issued the first Report was composed entirely of hospital physicians experienced in the rheumatism of children, and they passed the possibility of contagion over as of no practical importance. In this they were at one with hundreds of other physicians up and down the country. Is it likely that for years they have been studying a disease which is really infectious and they did not know it? If it may be said without impropriety, the interest in the disease at St. Mary's Hospital has always been particularly keen, as becomes the school of Sibson, Broadbent, Cheadle, Lees, Poynton, Paine, Symes, Coombs, and others: we know nothing of its infectious nature there.

(*e*) There is one further point: that a theory of contagion is against all the modern bacteriological conception of the disease. The discussion of this in Part II of the B.M.A. Report is to the effect that the bacteriological problem has swung away from the difficulty of accepting a streptococcus as the causative micro-organism, to the difficulty of understanding how an apparently normal inhabitant of the digestive tract can take on such a definite pathogenic role. If this be so, the part played by contagion must be at most of the slightest importance, analogous, as has been quoted above, to such a possibility in pneumonia and appendicitis. It may seem unmannerly to suggest that in scientific matters there are such things as fashions, but to many of us specially interested in rheumatic problems the persistent reiteration that we know nothing of the causative agent of rheumatism, nor even if it be an infection at all, seems little other than a fashion and a fatigue. To write as though the researches of Poynton and Paine had taught us nothing and pointed nowhere, seems as inaccurate as to suggest that the present efforts being made against juvenile rheumatism are not in reality the outcome of Poynton's many years of pioneer work and teaching.

6. *The Influence of Damp Dwellings.*

The first B.M.A. Report expressed the opinion that living in damp houses predisposed children to the *rheumatic infection, and regarded this as an important* factor in causing so much of the disease in this country. As the evidence in favour of this view has been summarized in the Appendix to their second Report[3] it is not necessary to restate it here, except to say that the world distribution of rheumatism and its seasonal incidence in England make it almost impossible to conceive that cold and damp should be factors of no importance.

The M.R.C. Report, on the other hand, states (p. 96):

"The housing inquiry threw but little light on the problem; dampness which has generally been credited with playing a large part in the causation of rheumatism was only slightly more frequent in the houses of the rheumatic families than in those of the others."

The material investigated for the M.R.C. Report consisted of the following (p. 10):

	Rheumatic.	Controls.
Hospital for Sick Children, London	121 cases	None
Royal Hospital for Sick Children, Glasgow ...	200 "	100 cases
St. Thomas's Hospital, London	400 "	100 "

The results obtained in investigating the housing conditions of the rheumatic and "control" families were:

	Rheumatic.	*Control* Families.
Hospital for Sick Children, London (p. 73) ...	30.0% damp	—
Royal Hospital for Sick Children, Glasgow (p. 73)	33.5% "	25% damp
St. Thomas's Hospital, London (p. 75)	39.8% "	33% "

Of the differences in the proportions of damp houses in the two sets of controlled figures, the Glasgow figures were said to be "probably significant" (p. 73), and the St. Thomas's figures to be "not significant" (p. 75).

The B.M.A. investigators made no attempt to deal with the difficult subject of what can be properly taken as rheumatic "controls," and contented themselves with reporting the proportion of rheumatic children who were, when first attacked by the infection, living in damp houses. The M.R.C. Report, on the other hand, dealt with the housing conditions in 200 control families, as we have seen, and it thus becomes necessary to deal with the reliability of the "controls" used. The figures produced in the M.R.C. Report illustrating the influence of damp appear open to criticism on four grounds.

1. The "control *children*" were "selected at random except as regards age and freedom from suspicion of rheumatic disease" (p. 11). It may readily be accepted that such children were apparently suitable for use as controls, yet when it is found that no less than 55 per cent. of them had unhealthy tonsils (p. 99) we see that, even in such a seemingly simple test as this, we are in difficulties in the matter of the material for "control" observations. With such a proportion of diseased throats who can tell what number of the children would develop rheumatism? This probability shows one of the difficulties *in attempting any* accurate control observations.

2. But with the "control *families*" there is in the M.R.C. figures a large element of error, for the so-called "control families" are by no means "non-rheumatic families." They are defined as follows (p. 9):

"These families were selected only in the respect that each contained a child attending the hospital for a non-rheumatic disease, and will be termed 'control families.'"

When the figures are examined it is found (Table 8, p. 16) that in the 200 "control families" there were 43 cases of rheumatism, apparently spread over (p. 18) at least 36 of the families. That these were not unimportant instances of previous rheumatism occurring in parents is shown by the following passage (p. 18):

"The difference in the incidence of rheumatism among the brothers and sisters of the rheumatic and control children respectively is striking, the percentage of those with rheumatism in the rheumatic families in the data from St. Thomas's Hospital being almost three times greater than that of the control families. . . ."

In view of these facts it can only be said that the so-called "control families" are not acceptable as controls. Any influence which the housing factor may have on the production of rheumatism would be, in such comparisons, considerably diluted by the presence of rheumatic families in the "control families."

3. There is no evidence in the M.R.C. Report that the housing conditions examined were those in which the disease first declared itself in the children.

4. The proportion of damp homes is much lower in the M.R.C. figures than in those of the B.M.A. Report. This is probably due to the use of a different standard of "damp," and as there appears to be no generally accepted standard such differences in separate investigations will be bound to occur.

That the M.R.C. Report was unable to confirm tional association between rheumatic infection houses is regrettable, but, considering the type of used and the stress laid on them, it is hardly Yet there is this to be said, that even with t used the figures concerning the influences of da proximity to water, low-lying sites, terrace opposed to tenement houses were in every case of damp being a factor, though showing only s ences in the rheumatic and in the "control" se is surely of significance, for were there noth theory of damp, the figures would hardly be li point one way.

Further, there is the new evidence, already q the M.R.C. Report, on the absence of rheumati children of the rheumatic stratum as are moved own homes and placed in Poor Law resident This is of great significance, for what has h these children to prevent their developing rh It might be thought that by their removal they h from poorer food and clothing, and greater ove but these do not produce rheumatism, for the less common in the poorest of the poor than in of poverty above them. Again, they might be disease by escaping from contact with other rheumatism is not a contagious disease. What happened? What factor, big enough to accoun a great change, has been altered? Is there any as likely as the condition of the house?

A REVIEW OF 1,000 CASES OF ASTHMA.

BY
FRANK COKE, F.R.C.S.,
LONDON.

THESE cases were seen between May, 1922, and the end of 1926, subsequently to the 270 cases the statistics of which I published in conjunction with the late Dr. Latham.

An etiological classification is still quite impossible, but cases reviewed in large numbers do tend to group themselves into more or less clearly defined types, differentiated by the prominence of some symptom or causal factor. Any one case may fall into several of the following types:

1. The type sensitive to foreign proteins.
2. The non-sensitive type.
3. The type that has asthma with colds.
4. The type that has asthma with enlarged tonsils.
5. The type that has asthma with catarrh.
6. The type having also paroxysmal rhinitis.
7. The colloido-clasic type.
8. The *periodic* type.
9. The type caused by bronchitis.
10. The type that also has a high blood pressure.
11. The type that has eczema.
12. The Adam's week-end type.
13. The seasonal type.
14. The type that is identified with localities.
15. The type that has asthma from severe shocks.
16. The occupational type.
17. The type sensitive to aspirin.

Type 1.—Many cases of asthma and similar complaints are due to an anaphylaxis comparable to the experimental anaphylaxis in animals. I am more than ever convinced of the value of the dermal reactions, and I have treated many patients successfully by this method. Reactions to wheat, milk, egg, dog hair, and cat hair have each led to many cases being freed from asthma without any other treatment than that based on these observations. A patient who had had asthma continuously for thirty-five years has now been entirely free for three years, after giving up his feather bed and pillows as a result of a small plus one reaction to feathers.

Statistics of Sensitization in 1,000 Cases of Asth

Age of Onset.	No. of Cases.	Percentage.	No. Sensitive.	Percentage.	Horse.	Cat.	Dog.	Other Animals.
0-5	293	29.8	238	80	120	89	64	44
5-10	113	11.3	95	88	44	39	16	17
10-15	64	6.4	44	68	18	13	14	14
15-20	61	6.1	37	61	18	13	10	5
20-25	70	7.0	34	48	7	9	7	8
25-30	81	8.1	48	60	14	14	5	8
30-35	77	7.7	31	40	8	6	8	5
35-40	64	6.4	29	45	5	4	6	4
40-45	53	5 3	15	28	2	5	4	2
45-50	40	4.0	9	24	2	1	—	1
50-55	35	3.5	4	11	—	—	—	—
55-60	24	2.4	3	12	—	—	1	1
Over 60	20	2.0	1	5	—	—	—	—

The chief points to be noted in this table Asthma commences far more commonly in bal early childhood than at any other time, and majority of such cases belong to the sensitive incidence falls steadily with increasing years, a small rise between the years of 25 and 30. lack of exercise and frequent colds may force a asthma to show itself.

The average duration of asthma in these 1,0 was fourteen years. I saw 539 males and 46 52 per cent. of them gave a history of asthma o in their near relatives.

Beyond the fact that I am now obtaining mor (58 per cent.) than formerly, the figures show change from previous statistics. The increa number of cases found to be sensitive is due t larger range of proteins I now use for testing in all. I use six different kinds of feathers—duck, pigeon, canary, and parrot—where form only one. The specificity of the reaction is so w that patients may react to one of these a

others. Face powders, silk, linseed, and other causes of sensitization turn up from time to time.

A particularly interesting protein is that of house dust; patients often give a reaction to the dust from their houses and to nothing else. American observers and van Leeuwen have also noted this. On one occasion I found I was obtaining an unusually large number of reactions to flour. Patients would react to it when they would not do so to anything else. In comparison with this we may note that van Leeuwen finds in Holland many cases of asthma due to the habit they have there of keeping flour and grain in the house and to its becoming infected with mites and moulds. I have added this infected wheat and the house dust to my routine tests. I have noted that patients in whose sputa moulds are detected suffer from a particularly pernicious type of asthma.

Having discovered proteins to which the patient is sensitive, three methods of treatment are available.

(*a*) *The avoidance of the protein.* The only proteins which it is difficult to remove from the patient's surroundings are the pollens, horse hair, house dust, and the proteins amongst which he works.

(*b*) *Specific desensitization.* Provided the correct dosage is arrived at by the dermal reactions using dilutions of the protein great success often follows this method.

(*c*) *The non-specific method of desensitization.* In certain cases peptone given intravenously is very valuable, in others I prefer the Danysz or mixed coliform vaccine, after which a particularly permanent cure may result. Autohaemotherapy and collosol manganese, either separately or together, have cured many cases.

Many patients are benefited by small doses of vaccine and made much worse with large doses. If a dose grossly upsets a patient, especially if it gives him an attack of asthma, a dose ten times smaller should be tried.

With perhaps half a dozen exceptions every one of this series of 1,000 cases of asthma has been tested to all those proteins which may be causing the asthma. Removal of those proteins to which the patient is sensitive cannot always be expected to be successful, because the patient may be sensitive to the other proteins or have asthma also from other causes which are not so easily discovered.

A young lady sensitive to wheat grew progressively worse instead of better after giving up wheat, until I found that she was also sensitive to compound extract of liquorice, which was contained in a prescription I had given her.

Type 2.—Clinically many of these patients are exactly like those of the sensitive type, to which they will be transferred as fresh causes of sensitization are discovered.

Type 3.—These patients are often sensitive to feathers.

Type 4.—These patients have asthma at school, at home, and away on holiday, periodically, perhaps once a fortnight. Very often nothing will cure them but complete enucleation of the tonsils. More rarely the nidus of infection is to be found in a nasal sinus, an appendix, or even a single tooth abscess. One woman lost this type of asthma after the removal of an unhealthy uterus.

Types 5, 6, and 7 will be dealt with in some future article.

Type 8.—Patients of the periodic type suffer from four or five tremendous waves of asthma each year. The attack may take a month reaching its height and the same in going again. After a month of freedom the whole thing occurs over again.

Type 9.—These patients bring up some sputum every day. A patch of bronchitis is often found in the lungs. An autogenous vaccine from the sputum is often entirely successful in curing this somewhat rare type.

Type 10.—The only symptom peculiar to this type is that the patients have a high blood pressure, usually round 200. Apart from that we find them distributed here and there throughout all the other types, and the asthma should be treated quite independently of this symptom.

Type 11.—Of the whole series of 1,000, 22 per cent. had eczema in early life; 30 per cent. of the sensitive type had had eczema and 34 per cent. of those sensitive to foods.

Type 12.—Asthma in this type is due to an intake of too much food, especially the last thing at night, and insufficient exercise. Though the patient has asthma from other causes, a strict diet will do much to help the majority of cases. This type is very fully described by Dr. James Adam of Glasgow in his books. I have many patients who keep entirely free by following his régime of starvation and exercise.

Type 13.—Typical of this is, of course, hay asthma. But I also find a number of patients who have pronounced asthma strictly limited to the months of August and September. Christmas is often a bad time; so many unusual proteins are met at that season. Recently I had a patient sensitive to holly.

Type 14.—A large number of patients are worse at the seaside, on clay soil, or in woods, especially if damp, or when in houses surrounded by trees.

Types 15, 16, and 17.—I hope to discuss these in a future article. Type 17 is quite the worst that I see. Naturally these patients never touch aspirin, but their asthma is almost continuous. They nearly all suffer from nasal polypi, a rare thing in ordinary asthmatics.

Results of Treatment.

In order to obtain statistics on the subject, 300 patients were written to. These had been seen by me between September, 1925, and December, 1926, and included every single case of asthma seen during that time. The answers received denoted the condition of the patient's health during the one to two years since coming to me. Replies were received from 223; of the rest two had died, both from strokes, and 14 could not be traced; the remainder have not answered. Many of the latter, to my knowledge, are abroad, and there is no reason to suppose the results obtained in these would be less favourable than from those who answered.

Replies received from 223 Cases.

(*a*)	"No better"	44
(*b*)	"A little better"	31
(*c*)	"Better"	32
(*d*)	"Much better"	17
(*e*)	"Very much better indeed"	34
(*f*)	"Practically free"; "Occasional attacks from overfeeding"; or "Perfectly well"...	65
		223

Taking those patients in (*e*) and (*f*) their average age was 27 and the duration of their asthma thirteen years. The average age of (*b*), (*c*), and (*d*) was 37 years, with a duration of asthma for fifteen years. Those "no better" (*a*) were 40 years of age and had had asthma for seventeen years on the average.

In conclusion, and considering that these 300 cases written to were in series and not picked cases, and that by far the larger majority were only seen once, I think the results obtained are sufficient to prove that these new methods of treating asthma have more than justified their trial.

CONVULSIONS OCCURRING DURING SURGICAL ANAESTHESIA.

BY

K. B. PINSON, M.B., CH.B., M.R.C.S., L.R.C.P., A.I.MECH.E.,

ANAESTHETIST, MANCHESTER ROYAL INFIRMARY, ROYAL MANCHESTER CHILDREN'S HOSPITAL, DENTAL HOSPITAL OF MANCHESTER, ANCOATS HOSPITAL, ETC.

THAT patients completely under the influence of a general narcotic, both children and adults, should develop general convulsions, and die of them, is extraordinary, but several instances have come to my notice. I have been an anaesthetist for nine years, and have made over 11,000 administrations. The first case occurred only two and a half years ago; I have been able to cut short the last few. The seizure is epileptiform, comes on at any time during the progress of the operation, and may continue until the end and after. It may quite cease, but start again later on, perhaps after the patient has reached the ward (without, however, having regained consciousness). In other cases, after some time, it stops of its own accord, or in response to treatment.

It begins with twitching of the eyelids, or arms, or about the mouth, and extends rapidly all over the body, suddenly almost; but before this, I think, some jerkiness

...tion becomes quite inefficient, and it may be difficult or impossible to keep a good colour even with oxygen. The convulsion is unremitting and severe, though there is not gross or violent movement, and it is obvious that it will quickly wear out the heart, even apart from the increasing respiratory insufficiency.

All the instances have occurred under ether, and nearly all in young people who have had an acute infection with more or less pyrexia. There have been fifteen in all, of which I will describe two or three typical ones.

The third case was perhaps the most singular of all, because when I saw the patient last he seemed on the way to a normal recovery from the anaesthesia, yet four hours later he was dead.

This was a boy, aged 7, with a gangrenous appendix, operated on at 6 p.m. in October, 1925, in hospital. From my own notes at the time: "Respiration very difficult owing to breath-holding in going under. Got generalized convulsions later on; these lasted till end of operation, but soon after stopped. Three hours later (in the ward) started again (after I had left the hospital). Artificial respiration; good colour; not round; respiration failed." Here I was impressed that the laboured breathing was the chief cause of the convulsions, the various muscle movements accessory to respiration overflowing apparently into the rest of the limb, face, and trunk muscles. There was no general peritonitis, and the boy was in good condition, but with some elevation of temperature; before he died, however, it went up to 107° F. The bomb method was here, as usually, employed. At the *post-mortem* examination there was nothing found that afforded any good explanation, and the coroner's verdict was in accordance with the medical evidence—that the fatal issue was due to some unknown effect of the ether.

It is most extraordinary that when I saw him, half an hour after the end of the operation, he should look perfectly well, though still unconscious, his colour, pulse, and breathing good, and so tranquil after the storm that there seemed not the least cause for anxiety.

The fifth case was at the same hospital, and the same method was employed. The date of the event and of my notes is April 13th, 1926.

"Strong healthy woman of 25; went under quite well; full blooded and rather muscular. Operation for removal of 'tarry' cyst difficult; moderate Trendelenburg position. Respiration full, unobstructed, good colour, and oxygen all the time. Suddenly, without the least warning, general convulsions—very severe; continued forty minutes. Anaesthetic stopped immediately, artificial respiration to regain regular breathing—no good: pressure carotids seemed to give a few seconds quiet. Began to get bluish, and pulse not so good; also temperature rose to 101.8°, and then to 103°. Very little sign of recovery from anaesthesia. Suddenly became quiet when mouth was gagged open preparatory passing an intratracheal tube, and insufflating with air, which therefore not done. Hewitt's airway tube has been in all the e. Respiration still rather jerky. In ward, pulse quite good, ng very slightly blue, breathing quiet, all right afterwards."

this case there was no infection or toxaemia, the an was in perfect general health, and the only excepble features were the Trendelenburg position, and that reathing was full. Immediate discontinuance of the did not, at any rate during forty minutes, relieve the s. But I will return to this matter. I then began haunted by the affection, for on two consecutive days e of 1926 I had a patient develop it.

eighth case was a girl, aged 19, in hospital with a ature raised to 102.5° F. by an acute pyosalpinx, came convulsed under deep narcosis. But I seem know what to do. The notes are:

ght on ether (bomb) till stitching up peritoneum, deep len onset of general convulsions. Immediately stopped c. Lasted (severe) until three or four minutes after when I noticed blueness due to oxygen being dis- However, convulsions soon stopped, and colour became respiration quiet, nice, but struggling during gular, but jerky. Temperature 101.2° F.; in bed imme- rwards."

eleventh case I have notes kindly written out the administrator, Mr. R. L. Holt, when in

ed 21, admitted September 15th, 1926, with acute spreading peritonitis, and a high temperature /60 grain atropine given shortly before operation previous cases, too, had in doses suitable to their chloride and ether induction; cyanosis observed t improved with oxygen, the airway being quite free. Though fully anaesthetized, spasm, followed by twitching the eyelids, and then general convulsions, came on, and a good colour could not be kept. By the time the operation had been speedily concluded, the convulsions, though less severe, had brought him to the point of death. Stimulants, artificial respiration, and cardiac massage were alike unavailing, and he expired while still in the theatre. *Post mortem* there was found a distinctly enlarged thymus.

All but four of these cases occurred in my own practice, and in all these ether was given by the "bomb" method. In the last six of them the convulsions, in response to my treatment, lasted only a few minutes, or did not become general. The onset is definitely recognizable and easily to be distinguished from "ether clonus," which is of a coarser and at the same time a more rhythmical form. Notes were made of them the same day in all except two.

It appears from these cases that the convulsions are similar and typical. Five of them ended fatally, and in the first and fourteenth the patients were already in an extremely grave state before operation; in most cases there was pronounced infection, but in some, particularly the fifth (quoted here), this was not so.

All but one, the first, were in young people and children. All had ether, most of them nothing else, so that this appears so far as a causal factor, but no particular brand, as several kinds had been given. No history of epilepsy, convulsions, or chorea was at any time obtained.

Why is it that it is only recently that these things have been observed—only recently that they have happened, since they scarcely could have escaped notice?

Two matters suggest themselves in explanation—the gradually increasing use, especially by beginners, of ether, and the adoption, as a consequence, of many coverings over the frame and face to concentrate the vapour. Neither of these is very convincing, as little or no change in either direction, that I am sensible of, has taken place in my own routine during the past two or three years.

It is to be seen that in most cases the breathing is first affected: it becomes jerky, insufficient, or stertorous, or there is cyanosis, and in some, from the beginning, has been difficult, laboured, or uncomfortably deep and full. In my own cases I have not been satisfied in every one that the breathing could in any way be taken exception to; but in most I have, and always I have felt that it would not be unreasonable to blame an invisible increase of CO_2; for its effects, in the way of deep and energetic breathing, have, as I say, been obvious enough. Even without this it is fair to think that instead of resulting in steady and deep inspirations and in perfectly co-ordinated action of important muscles, it may produce only partly co-ordinated and jerky efforts, which can easily be supposed to extend to the whole body in conditions where, for some reason or another, there may be abnormal irritability of other muscles—such conditions, I mean, as pyrexia, toxaemia, and ether narcosis. Quiet respiration is regular enough—in fact, when breathing is quiet, it is the more regular—but under general anaesthesia it is frequently but a short step from the accustomed rhythm to various irregularities, both of a rhythmical and an arrhythmical sort; so that I have come to regard the convulsion as largely the outcome of the extensive action of the CO_2 in patients who are sensitive to this naturally, or by reason of toxaemia, pyrexia, and so on, and who are under the influence of ether, a substance itself having a marked effect on breathing.

I have on occasion seen persons inhaling ether take breaths constantly increasing in depth, vigour, and rate, until in a few moments the whole frame is in tonic spasm, where they remain for some moments quite unable to move or breathe at all. Moreover, those so-called "athetotic" movements come particularly to those patients who, by reason of rigidity during the struggling stage, have difficulty, often lasting some minutes, in drawing their breath—being, as it seems to me, overflow movements of muscles other than accessory muscles of respiration, and lasting in a disorderly manner for an unexpectedly long time. Such cases throw light on the subject of this report, and however it may be, treatment based on this assumption has so far been successful. It is directed to the riddance of excess CO_2, and must be prompt. Luckily some moments' warning is given of the impending seizure

by twitching of the eyelids and mouth, jerkiness of the breathing, especially inspiration, or some strange movement or sound, and so the essential thing can be accomplished—*the immediate removal of all coverings from the face* before the convulsions have set in. Frame, towels, everything, are taken right away, and the air of the room given free access; any obstruction must be completely relieved, and a gentle stream of oxygen allowed to flow towards the mouth. In this way the CO_2 will diminish as much as possible by natural means. Recovery from the anaesthetic, so delayed in most of these cases, is permitted to proceed, until it is utterly impossible to have the patient come round any more, when pure chloroform may be given in small quantities and by a quite open method, though, indeed, this will often not be needed. The success of this procedure depends on the promptitude with which the onset of spasms is foreseen.

A field for investigation is here; but the most important thing for the time being is that as many as possible should know how to recognize the condition and treat it.

THE APPENDIX REFLEX.*

BY

A. B. MITCHELL, M.B., B.CH., F.R.C.S.I.,

SURGEON, ROYAL VICTORIA HOSPITAL, BELFAST.

THE appendix reflex, giving rise to pyloric spasm, followed by hyperacidity and symptoms suggestive of gastric or duodenal ulcer, is now well recognized.

The object of this paper is to suggest that in certain subjects, with unstable nervous system, a diseased appendix may be the exciting cause of symptoms of an entirely different character. I propose to illustrate this suggestion by reference to a series of cases which have come under my observation, in most of which the possibility of an appendical origin had never been suspected.

CASE I.—*Migraine.*

In 1912 a country farmer, aged 45, was sent to me with a view to operation on his stomach, owing to repeated attacks of vomiting.

His history appeared to be a typical one of migraine. As long as he could remember he had suffered from violent headaches, associated with the appearance of spots before his eyes and followed by severe vomiting. At first the attacks occurred only two or three times a year, then once a month. When I saw him they came once a fortnight. He wakened with them, and was completely prostrated for a whole day, and unfit to work on the following day. He had no history of abdominal pain at any time. The stomach appeared normal. I regarded the case as one of migraine, and said I could not give any guarantee of relief by operation. We might possibly find a chronic appendix, but operation would be largely exploratory.

I saw no more of him for four years. He came back stating that his attacks had become intolerable. They now lasted four days. He was five days in bed. He had to sell his farm as he was quite incapable of looking after it. He asked me to "open him up" and see if anything could be done.

At operation, which was carried out through a right paramedial incision, admitting of a thorough examination of the whole abdomen, we could find nothing abnormal except a very large, chronically inflamed and distended appendix, dipping into the pelvis and adherent there.

He made an uneventful recovery. He had no recurrence of headache for a month after operation. When I last heard of him, a year later, he still had occasional headaches, but they never lasted more than a day, and he was again farming.

I have no doubt whatever that if this man had had the appendix removed in early life the attacks of migraine would have disappeared completely.

CASE II.—*Migraine.*

Shortly after operating on Case I, in 1916, a school teacher, a lady aged 40, came to me complaining of steadily increasing migraine. Her attacks, which at first had been monthly, had now become weekly. They were very severe, and unfitted her for her duty for two days at a time.

All the usual investigations had been made. The eyes had been thoroughly tested, and reading glasses supplied, without relief. The uterus was normal in size and position, functions regular. Urine normal in every respect.

In view of the previous case I suggested the possibility of relief by operation, at the same time explaining that no guarantee could be given. She at once agreed, saying she could carry on no longer as she was.

At operation we found (1) a well marked chronic appendix, adherent to the caecum; (2) a cholesterine gall stone, the size of a small pea, in an apparently healthy gall bladder.

The appendix and the gall stone were removed, and the gall bladder drained. She made an uneventful recovery.

Even after the operation, with knowledge of the pathological condition, we could elicit no history suggestive of either appendix or gall-bladder trouble.

I had a letter from her a year later informing me that she had now only a very occasional headache, which never interfered with her work.

CASE III.—*Migraine, with Glycosuria.*

In January, 1919, I operated on a young medical man, whose own account of his case speaks for itself.

"For several years previous to the onset of glycosuria (1917) I had periodic attacks of severe headache, associated with indigestion and loss of appetite, but no vomiting. The attacks lasted from two to four days, and were always in the frontal region, on one side or other, but never both sides together. The most tender spot was the exit of the supratrochlear nerve from the orbit. At times I could not use my eyes for the pain.

"The attacks continued till you operated on me in January, 1919. I think you found a chronic retrocaecal appendix, which you removed. This was associated with some cholecystitis, so you drained the gall bladder for a few days.

"Since that time I have been practically free from headache. I am also quite free from glycosuria, and am on an ordinary carbohydrate diet."

CASE IV.—*Cyclical Vomiting: Acidosis.*

Early in 1920 I saw, with one of our leading medical men, a little girl, aged 10. Since she was 2 years old she had suffered from attacks of acidosis with violent vomiting, occurring every two or three months, as the result of which she was confined to bed for some days, but was always relieved by large doses of alkalis. She never had any definite abdominal pain till the attack in which I had seen her. She then had definite symptoms of appendicitis. Immediate operation was advised, but it was with considerable difficulty that her parents could be persuaded to have this done. They said she was terribly nervous, and the very idea of operation would put her out of her mind. However, they finally consented.

At operation we removed a distended, congested appendix. Recovery was uneventful. Her attacks of vomiting and acidosis disappeared completely. Her nerves quieted down. In a short time she became a normal child and has remained so ever since.

CASE V.—*Cyclical Vomiting: Acidosis.*

On January 1st, 1923, I saw a little girl, aged 6. She was quite well till 2½ years of age. She then began to have severe "bilious attacks" once a month or oftener. The attacks increased in frequency and severity until 1923, when I saw her. They commenced with sneezing, running of the nose, then cough, lasting for a day, next day violent and persistent vomiting, which lasted twelve hours and completely prostrated her, leaving her greatly exhausted all the following day. She had some acidosis with each attack, but no headache. She never had any abdominal pain, except some muscular pain *after* the vomiting.

A finger in the rectum elicited some tenderness high up when pressure was made with the other hand in the right iliac fossa—that is, a bimanual examination of the ileo-caecal region, which is so useful in children. Otherwise nothing could be made out.

She was referred to a specialist for a thorough examination of the nose and nasal pharynx. He reported that there was *nothing* to account for her attacks. We accordingly operated, and removed a long, distended, corkscrew-like appendix. A month later she had one of her old attacks, then another slight one, after which they completely ceased. Her doctor reported on January 20th, 1925, that she had remained perfectly well ever since.

Osler says: "In young children acetone acidosis (cyclical vomiting) may give difficulty in diagnosis from appendicitis. There may be severe vomiting, with abdominal pain, and the caecum may be distended and tender. The smell of acetone from the breath and the urinary findings should distinguish." (Tenth edition, p. 533.)

I desire to suggest that in some of these cases appendicitis may be the *real disease, the acidosis* merely a reflex effect.

Appendicitis in children is very common, much more so than is generally recognized. I believe the majority of cases of so-called colic are primarily appendical, and that a large proportion of the cases of so-called chronic appendix which are met with to-day during abdominal operations have originated in early childhood. In the "nervous child" such an appendix may give rise to a variety of reflex symptoms, even in the absence of any local signs.

CASE VI.—*Epilepsy.*

In July, 1919, I was asked to see Mr. H., aged 37, who for years had been the subject of epileptic attacks. In 1904 he had an attack of what seemed to have been appendicitis, and was

*This paper was read before the Section of Surgery of the Royal Academy of Medicine in Ireland on February 18th: the discussion which followed was published in the JOURNAL of March 19th (p. 517).

up for a week. When I saw him he was the subject of nic indigestion of the appendical type. He was taking bromide ularly to control his epilepsy.
peration was advised (1) for relief of the indigestion, (2) in hope that it might benefit the epilepsy. A large, distended, erent appendix was removed from the ileo-cæcal angle.
le made an uneventful recovery. He had no epileptic attack for months after operation, and since that time the attacks have n much less frequent and less severe.

t seems reasonable to infer that if this appendix had n removed at a much earlier stage, before the epileptic it had become confirmed, the result would have been ch better, and possibly the disease might have been ed.

CASE VII.—*Petit Mal.*

n May, 1922, I saw a boy, aged 10, a doctor's nephew, who had some years suffered from attacks of petit mal, which were reasing in frequency. I was asked to see him owing to an ack of abdominal pain. We regarded the case as one of pendicitis, and advised operation. His mother at once pointed that he had these nervous attacks, and asked whether there uld be any chance of the operation making them worse. Our ly was that there was every reason to hope it would make m better.
l operation we found a distended, obstructed appendix.
le made an uneventful recovery. The attacks of petit mal ppeared, and he is now a boarder at a public school, in ellent health.

Let it be clearly understood: I do not propose that ry case of migraine, cyclical vomiting, or epilepsy uld be submitted to an appendicectomy.
I do wish to point out that this group of cases, which y be classed with hysteria, neurasthenia, and certain es of mental disease, have one feature in common—it is, a nervous system so unstable that it is liable to upset by some slight reflex stimulus which would not turb a normal individual.
A thorough examination for an abdominal focus should carried out in every instance. A misplaced uterus, or movable kidney, will often afford an explanation, but venture to suggest that a diseased appendix will prove be the exciting cause much more frequently than we ve hitherto suspected.
When there is good reason for suspicion of that organ, pendicectomy should be seriously considered.

THE TREATMENT OF RODENT ULCERS NEAR THE EYE.

BY

ZACHARY COPE, M.S., F.R.C.S.,

SENIOR SURGEON TO THE BOLINGBROKE HOSPITAL.

HE satisfactory treatment of rodent ulcers in the region the eye and nose is sometimes a little difficult. For ry small lesions the application of carbon dioxide snow y be efficient, in other cases the application of radium treatment by *x* rays may be recommended, but none of ese methods is quite so speedy or efficient as excision, that can be practised without causing deformity of the ce.
If surgical measures are undertaken it is wise to remove e ulcer with a margin of at least half an inch surnding it. If the ulcer is but the size of a threepenny-t its removal may leave a space necessitating a skin aft, for to bring the edges of the skin together will stort the eyelids or nose. The difficulty of applying a in graft in the region of the inner canthus and ala nasi readily understood. It is almost useless to apply grafts the Thiersch method unless firm and equable pressure maintained, and the difficulty of maintaining such ressure in this region is easily appreciable. Following e lines of the well known work of Esser, which has en so skilfully developed by Gillies and others, I at first pplied grafts moulded upon Stent's composition. This ve fairly satisfactory results, but the material upon hich the grafts were moulded was rather hard to press gainst the bony root of the nose, and if the mould was ot absolutely perfect equable pressure over the whole area as not maintained. In searching for a suitable moulding aterial I thought of a substance which would be less hard hen cold, but would enable pressure to be applied over the whole grafted area. Plasticine was therefore tried and proved suitable. This material was used because it was most readily obtainable, but ordinary artist's modelling clay would, I think, serve equally well, if not better.

The technique of the method is as follows. Under a general anæsthetic the ulcer is excised with half an inch of apparently healthy skin all round. Any bleeding vessel is seized by artery clips and oozing from smaller vessels checked by gauze pressure. Fine catgut may be used to ligature any larger vessel if necessary, but it is better to do without ligatures if torsion and forcipressure will suffice. Whilst the raw area is being made dry by pressure the surgeon takes up a piece of modelling clay which has been boiled in order to sterilize it, and breaks off a portion of a suitable size for the graft. It is then carefully moulded over the raw surface and contiguous surface of the root of the nose and upper or lower eyelid, and put aside whilst the outer aspect of the thigh is exposed for the purpose of cutting the grafts. The grafts are cut in the usual way by a razor or special knife, and are placed on the area of the clay previously moulded on to the raw surface, with their deep or raw surface outwards, so that when the mould is applied to the part of the face operated upon raw surface of graft meets raw surface of face. The grafts should more than cover the actual part of the *clay which fitted the ulcer. The clay with grafts on it is* carefully fitted on to the place from which the growth was removed and pressure is maintained by strips of strapping. A simple dressing is applied over this. The parts are not touched for about ten days, at the end of which time the dressing and clay can be removed. The grafts should then be firmly adherent and no raw surface be seen. A simple dressing may be applied and maintained in position by strapping for a week or two. The superficial scab of epithelium will gradually separate and leave a healthy depressed and firm scar. In the course of a few months this scar rises and restores an almost normal appearance to the site from which the rodent ulcer has been removed.

MICROSCOPICAL AND CHEMICAL EXAMINATION OF STOOLS IN YOUNG CHILDREN.

BY

ETHEL CASSIE, M.D., D.P.H.,

ASSISTANT MEDICAL OFFICER OF HEALTH AND MEDICAL SUPERINTENDENT OF THE CARNEGIE INSTITUTE, BIRMINGHAM;

AND

URSULA COX, M.R.C.S., L.R.C.P.,

ASSISTANT MEDICAL OFFICER FOR CHILD WELFARE, BIRMINGHAM.

IN order to ascertain what information might be gained by systematic examinations of stools in young children, careful observations were made during 1924 and 1925 on patients in the observation ward at the Carnegie Institute, Birmingham. As there was some variation in method and nomenclature during the early period, these notes deal exclusively with the cases of 1925, when a more definite system had been instituted.

Chemical examinations have been made with the object of ascertaining the reaction, and the presence or absence, of occult blood; the microscopic examination has included Gram-stained films for the bacterial flora, and examination for pus, fat, etc.

Stools have been examined from cases of subacute and chronic enteritis; convalescents from enteritis; children with no intestinal disorder and with normal stools; cases of constipation; and breast-fed infants. All the patients were children under the age of 5.

(A) *Chemical Examination.*

In the cases suffering from enteritis, 54 per cent. of the stools were acid, including all the more acute cases. Blood was found in 83 per cent. of the cases. Pus and epithelial cells were frequently found on microscopical examination of the wet preparation. As the patients improved the stools became alkaline, only 22 per cent. remaining or becoming acid. Blood was still found in 50 per cent. of the patients who had clinically quite recovered. Of the normal stools, 90 per cent. were alkaline, and blood was

found in 20 per cent., although the patients showed no sign of gastro-intestinal disorder. Most of these cases, however, had a history of previous intestinal disorder. Constipated stools were always alkaline, and blood was present in 33 per cent. All the breast-fed infants whose stools were examined were suffering from enteritis, all the stools were acid, and 80 per cent. contained blood.

The high percentage of stools containing occult blood in the subacute and chronic intestinal disorders of infancy is a fact which has not apparently attracted attention. The test used was the benzidine test, which is very delicate. The persistence of a positive reaction after convalescence and even recovery are established is also a point of some interest.

(B) *Bacteriological Examination.*

It has been found impossible to ascertain the causal agent of bowel irritation from the examination of the Gram-stained films. They showed a very mixed flora which might exhibit a preponderance of Gram-negative or Gram-positive organisms. In many cases of enteritis, particularly the acute cases, the Gram-stained film showed a large number of Gram-positive cocci (staphylococci and, more rarely, streptococci); with recovery the film tended to become more Gram-negative. This may have some significance. There is no such thing as a "normal" Gram film. Cocci, however, are rarely a prominent feature. The Gram-stained films in the breast-fed infants showed almost in every instance a uniform picture of slender Gram-positive rods, which may be taken as the normal flora of the breast-fed infant's stool.

In cases of enteritis treated with lactic acid milk (culture) the change in the flora was interesting; it was to a higher percentage of Gram-negative organisms.

The following are the tabulated figures:

	Number.	Alkaline.	Acid.	Neutral.	Blood.	Mixed Film.	Gram + Predominance.	Gram - Predominance.	Cocci +.
Enteritis stools ...	46	44%	54%	2%	83%	—	28%	18%	54%
Convalescent stools	31	68%	22%	10%	50%	13%	32%	42%	13%
Normal stools ...	20	90%	10%	—	20%	90%	—	—	10%
Constipated stools ...	6	100%	—	—	33%	100%	—	—	—
Breast-fed infants' stools	5	100%	—	—	80%	20%	80%	—	—

Memoranda:

MEDICAL, SURGICAL, OBSTETRICAL.

TAPEWORMS AND MEAT INSPECTION.

THE following account may be of interest partly because human cases of tapeworm infection are nowadays supposed to be comparatively rare in England, and partly because it raises a doubt whether even fairly close routine meat inspection is likely to detect the small cysts of *Taenia saginata*.

The three patients all came to consult me within a week, and it would be best, perhaps, to give a short history of each.

CASE I.

On January 12th, 1927, Miss A. came to me because for about eighteen months she had been passing some whitish things like vermicelli in her motions. I found them to be segments of *Taenia saginata*; on treatment with extract of *filix mas*, the tapeworm, many feet in length, was evacuated. The patient had suffered from severe nervous depression and "biliousness."

CASE II.

On January 18th, 1927, Mrs. B. told me that she was passing some flat, whitish objects. On examination of the stools, segments of *Taenia saginata* were seen, some well over an inch long. Treatment with extract of *filix mas* resulted again in the evacuation of a tapeworm several feet in length. The patient had suffered since 1924 from backache and depression, and is now feeling much better; curiously, she had been putting on weight, a rather surprising symptom for a tapeworm to produce.

CASE III.

On January 17th, 1927, Mr. C. consulted me, bringing with him a pot containing about six feet of tapeworm that he had just passed. This again proved to be *Taenia saginata*, and the rest of the tapeworm (quite six feet more) was evacuated by means of extract of *filix mas*. He looked rather thin and anaemic, and felt depressed.

It has, I think, been absolutely proved that *Taenia saginata* in man is due to the eating of infested beef. Yet Cases I and II are both religious Jewesses and have never been out of England; they take their meat from different butchers, but this, of course, does not exclude the possibility of the infection having come from the same animal. Their meat is always examined both by the British meat inspectors and by the Jewish trained slaughter officials, and at home, as well, during the process of "koshering" any abnormalities are likely to be detected. Case III has never been further away from England than France; he states that he ate a great deal of partially cooked meat in France about two years ago.

The specimens from the above cases were identified by Professor R. T. Leiper, F.R.S.

London, N.5. J. VICTOR LANDAU, M.D.Lond., D.P.H.

ULTRA-VIOLET RAYS IN THE TREATMENT OF RICKETS.

SINCE the curative properties of artificial ultra-violet rays in rickets were demonstrated, eight years ago, there has been difference of opinion as to the most suitable source of the rays. During the past eighteen months we have attempted to ascertain the relative curative value of different types of lamps.

All the patients selected suffered from severe active rickets, as shown in radiograms of the wrist; radiograms taken at frequent intervals formed the criterion of the progress of healing and of ultimate cure. All the patients were kept in the same environment and were given a standard antirachitic diet rich in fats and poor in carbohydrates; in addition they were all given cod-liver oil. The ages of the patients ranged from 1 to 4 years.

Group A.—Fifteen patients were given the standard diet and cod-liver oil, but no ultra-violet radiations. It was found that on an average a severe case of rickets was cured in fifteen weeks. These cases are included for comparative purposes.

Group B.—Eleven patients were exposed on alternate days, at a distance of 30 inches, to the rays of an open-flamed carbon arc lamp consuming 35 amperes, for periods of ten minutes increasing to one hour. It was found that these patients were not more rapidly cured than those in the first group, the average time being fifteen weeks.

Group C.—Eight patients were exposed on alternate days to the rays of an arc lamp burning electrodes of carbon cored with tungsten-molybdeno powder, at a distance of 32 inches. The initial exposure of two minutes was slowly increased to five minutes. It was found that the average time necessary to effect a cure was eight weeks.

Group D.—Four patients were exposed twice a week to the rays of a K-B-B mercury vapour atmospheric lamp, at a distance of 20 inches. They were cured in approximately five weeks.

The radiological evidence of cure does not apparently synchronize with the clinical evidence, for the square head, beading of the ribs, and deformities of the limbs may persist long after the radiogram of the wrist presents a normal picture. The antirachitic properties of ultra-violet rays seem to be due to those having a wave-length of 3,000 Angström units or less. It is probable that these rays, being absorbed by the deeper layers of the skin, there activate a vitamin precursor, converting it into a potent antirachitic vitamin, which is liberated into the circulation.

The mercury vapour lamp, giving as it does an abundance of rays around 3,000 Angström units and beyond it, proved the most potent in the treatment of rickets. The rays emanating from the carbons cored with tungsten-molybdeno powder, while not being so powerful, were still definitely antirachitic; whereas the carbon arc lamp with its wealth of "near" ultra-violet rays does not apparently possess any marked antirachitic properties.

We wish to thank Dr. P. Macdiarmid, the medical superintendent of Alder Hey Hospital, for his permission to make use of these statistics.

CARCINOMA OF THE MALE BREAST.

CASES of carcinoma of the breast in males are sufficiently rare to warrant placing on record.

A man, aged 63, was sent to me by Dr. Langmuir with a view to admission to the Glasgow Royal Infirmary. The patient stated that the condition began several months previously as a small "boil," which repeatedly broke down and healed again, and gradually increased in size. He had been losing weight for the past six months, and, for a couple of weeks prior to admission, had experienced pain in the breast region, and extending down the arm.

An ulcer about the size of half a crown, covered by a brown crust, and surrounded by an inflammatory zone, was found in the position of the right breast, the nipple having been entirely destroyed. It was hard to the touch and was adherent to the pectoral fascia, but moved on the subjacent structures. The axillary glands were extensively involved and hard; several were much enlarged.

Operation was performed as for removal of the female breast, together with muscles and axillary contents. The areolar tissue in the axilla was unusually dense and fibrous, rendering removal of the glands more difficult than usual, particularly those surrounding the vein. Enlarged glands extended up to the apex of the axilla, under the clavicle.

Microscopical examination of the tumour and of the axillary glands by Dr. Burton showed it to be a scirrhous carcinoma of the atrophying type. The Wassermann reaction was negative.

The patient has made an uninterrupted recovery.

JOHN A. C. MACEWEN, M.B., C.M., F.R.F.P.S.,
Surgeon, Royal Infirmary, Glasgow.

CAVERNOUS ANEURYSM OF THE CAROTID.

THE following record of a rather unusual case in which the diagnosis of carotid cavernous aneurysm was made will be of interest.

A married woman, aged 30, had suffered since adolescence from severe headache on the right side, accompanied by attacks of vomiting, and preceded by sensations of spots in front of her eyes. Since marriage, eight years ago, her husband had detected a curious noise proceeding from her head. Five years ago she had "attacks" preceded by hunger; her lips became red, she suffered with cold shivers, and then developed biliousness and faintness. She had been losing weight. She had scarlet fever four and a half years ago, and four years ago a convulsive attack nine days after the birth of her second child; since then the attacks had been worse. She menstruated every three weeks with severe loss.

I found the thyroid gland uniformly enlarged, and a systolic murmur was audible over it. There was slight exophthalmos. The cardiac apex beat was 5½ inches from the mid-line, and there was a systolic apical murmur connected both inwards and outwards; this murmur became less when she was kept in bed, and it did not appear to be organic. She had a fair tolerance for exercise; there was no sign of failure of compensation, and the blood pressure was 120/80. By listening over the head a systolic and diastolic murmur could be heard behind both ears, and a systolic murmur alone over the vertex. The patient was aware of a noise in her head, which became worse when she was worried. No abnormality was found in the eyes and there was no pulsating exophthalmos.

I came to the conclusion that this was a case of carotid cavernous aneurysm; I find in the literature that this may occur spontaneously after childbirth. Assuming this diagnosis to be correct, the question is whether such a condition would account for the symptoms, including those resembling migraine. Could such a condition be congenital and be made worse by childbirth? Could any effective treatment be recommended?

Johannesburg. H. L. HEIMANN, M.D., M.R.C.P.

INFLUENZAL NEPHRITIS AND PYELITIS.

NEPHRITIS and pyelitis seem to have been more common complications of influenza during the recent epidemic than is usual. To the several cases already recorded in the BRITISH MEDICAL JOURNAL (December 11th, 1926, April 2nd, 1927, etc.) can be added some cases treated at the Bristol Royal Hospital for Sick Children and Women.

E. P., female, aged 13. Influenza; followed by (about a week later) epithelial casts, red blood corpuscles in urine, and slight generalized oedema.

E. J., female, aged 6. Combination of epithelial casts and pus cells in urine, and slight oedema.

J. B., female, aged 11. Pyrexia; many red blood cells and some pus cells.

S. B., female, aged 12. Pyrexia; many red blood cells and many pus cells (sent in as an acute abdominal case).

The above cases were characterized by the rapidity with which they cleared up. Cases of haematuria (influenzal) have been recorded (*Medical Echo*, March, 1927) which, together with the cases of albuminuria and those of true nephritis, raise the question as to whether they were different stages of the same disease, just as in the respiratory system one may get aborted cases of pneumonia.

In the eighth edition of Osler's *Principles and Practice of Medicine* it is noted that G. Baumgarten has called attention to the frequency of nephritis as a complication of influenza, though Holt states that it is only occasionally seen.

I am indebted to the kindness of Dr. O. C. M. Davis, senior physician to the hospital, for permission to submit these cases.

J. L. DELICATI, L.M.S.S.A.Lond.,
House Physician, Bristol Royal Hospital for Sick Children and Women.

Reports of Societies.

ICHTHYOSIS AND CANCER OF THE SKIN.

AT a meeting of the Section of Dermatology of the Royal Society of Medicine on May 19th, DR. J. H. SEQUEIRA, the President, in the chair, a paper was read by DR. LOUIS SAVATARD of Manchester, on ichthyosis and cancer of the skin, with special reference to mule-spinner's cancer.

Dr. Savatard considered that it was quite justifiable to regard xerodermia pigmentosum as a precancerous inflammation of the skin, because in this comparatively infrequent affection it was the rule rather than the exception for cancer to supervene, but he did not think that the fact that xerodermia simplex, or ichthyosis simplex, was also a frequent precursor of cancer was yet recognized as it should be. He considered ichthyosis of the skin of importance as predisposing to skin cancer. In some cases of external cancer, by making a routine examination of the skin of the whole body, he had found lesions not previously suspected even by the patient, and in some of these ichthyosis was present also. This was especially the case when carcinoma was found supervening on a keratotic skin condition. It was not improbable that the keratosis was secondary to the ichthyosis, and might be the precursor of all types of carcinoma and the first sign of squamous carcinoma to be clinically recognized. Dr. Savatard then exhibited a patient whom he had brought from Manchester, illustrating this condition, together with slides of about a dozen cases. He mentioned that Dr. Prosser White of Wigan had described what he called "shagreen skin" occurring in mule-spinners, but among the Manchester mule-spinners whom he had seen he had not noticed this condition, and he regarded this type of skin as only ichthyosis, which was fairly common in Lancashire. Among 400 mule-spinners whom he had seen the incidence was 5 per cent. These mule-spinners, whom he had had an opportunity of examining at their work, were of various ages, and the twenty of them who had ichthyosis (in ten only in a mild degree) included both youths and men. Two out of the twenty had suffered from cancer of the scrotum. From the observations he had been able to make he was convinced that ichthyosis was an important etiological factor in mule-spinner's cancer. He was sorry to see that the departmental committee on mule-spinner's cancer[1] had reported that in the absence of exposure to mineral oils there would be no mule-spinner's cancer. Dr. Robertson, medical officer of health for Darwen, as a result of his own investigation, had come to the opposite view.

DR. ARTHUR WHITFIELD said that in his opinion Dr. Savatard had attributed to ichthyosis an importance which was hardly warranted. It was true that the ichthyotic skin was a poorly nourished skin, especially in respect of the absence of true maturity of the horny cell, as well as the production and exudation of grease. Since the ichthyotic patient started life with a skin defect in the

[1] Departmental Committee Report on Occurrence of Epitheliomatous Ulceration among Mule-Spinners (1926). London: H.M. Stationery Office. Summarized, BRITISH MEDICAL JOURNAL, April 24th, 1926, p. 746.

direction of senility he might on that account show a tendency to the development of skin cancer. The speaker had not seen malignant keratosis in a keratotic subject.

Dr. GRAHAM LITTLE thought it must be rare for carcinomatous changes to be seen in association with senile keratosis.

Dr. H. MACCORMAC said that for a long time he had been definitely of opinion that there was a tendency for the prickle-cell type of carcinoma to take origin in some condition of the skin which could be definitely termed "pre-cancerous." He had seen, especially among Australians during the war, cases in which cancer developed on portions of the skin which had been exposed for long periods to powerful sunshine. The term "senile keratosis" was variously used by different dermatologists.

Dr. A. M. H. GRAY thought it would be comparatively simple to find out how many cases of carcinoma of the scrotum occurred among those whose work was not concerned with oils, tar, pitch, soot, or other substances which were well known to be skin irritants. His opinion was that it was rare to find carcinoma of the skin unassociated with occupations of this kind.

Dr. SYDNEY THOMSON remarked that among a large number of patients with ichthyosis whom he had seen none developed a warty growth of any sort. He reminded members that there was a well marked topographical distribution in the case of ichthyosis, and this was not the case with "senile skin."

Dr. H. W. BARBER raised the question of the association of multiple superficial basal-celled carcinomata with psoriasis, and asked whether psoriasis was more likely to occur in people who had a skin habitually dry than in people with normal skin.

Dr. SAVATARD, in reply, said that he fully recognized that oil, tar, soot, and like substances caused cancer. But his point was that if a routine examination of the whole of the skin of patients was made, cancer would be found more frequently in those with an ichthyotic skin than in others.

INTERNAL SECRETIONS OF THE OVARY.

AT a meeting of the Section of Obstetrics and Gynaecology of the Royal Society of Medicine on May 20th, Dr. A. DONALD in the chair, Dr. A. S. PARKES read a paper on the internal secretions of the ovary.

Dr. Parkes stated that up to the present time all that was known about the nature and properties of these secretions had been derived from experiments upon animals. His own work had been done on rodents, but he thought that it would be safe to assume that the secretions of the ovary were governed by the same laws in all mammals. The ovarian cycle consisted in the maturation of the Graafian follicles leading up to the production of the corpus luteum, together with the associated changes in the accessory organs of generation. The changes in the uterus during this period were well recognized, decidual tissue being formed in the endometrium in preparation for reception of the fertilized ovum. In the case of the mouse and rat these preparatory changes in the uterine mucosa were slight, as the ovarian cycle did not go beyond maturation of the ovarian follicles, and no corpus luteum was produced until fertilization. In the pig and the cow, however, the reverse was the case; the corpus luteum was fully developed and persisted for a long period, and, consequently, extensive preparation was made by the endometrium. Thus decidual tissue was found in the uterus in large amounts until the corpus luteum involuted. The "luteal phase" was also predominant in the ovarian cycle of the dog and the rabbit. Instances of pseudo-pregnancy in these animals were well known and numerous: the rabbit plucking its fur to make a nest, and the mammary glands of the bitch undergoing hypertrophy accompanied by secretion of milk. In the human being the same state of affairs existed, though perhaps not to so marked a degree. Ovulation occurred about thirteen to fifteen days after the first day of the preceding menstrual period. The premenstrual changes in the uterus, breasts, and other organs of generation were probably under control of the corpus luteum, which became functionally active at this stage. The relation of the ovar as a whole to the accessory organs of generation was o great interest; thus its presence was necessary for th development and activity of these organs and of th accessory glands affected by the ovary. The control wa supposed to be endocrine in nature. The extraction o the active principle, or principles, of the ovary was nex considered, particularly with regard to the production o oestrus in the ovariotomized animal. The difficulty o finding a reliable test for true oestrus had been largel overcome by the researches of Allen and Doisy in America who demonstrated the characteristic changes found in vaginal smear during the oestral cycle. The original soure of the oestrus-producing hormone was the liquor folliculi theoretically, therefore, maturation of the Graafian follicle produced oestrus. Substances which produced this effec had, however, been isolated from the ovarian stroma, th fluid in the corpus luteum, and from the placenta. To th corpus luteum had been ascribed the powers of (1) sensi tization of the endometrium for the reception of the ferti lized ovum; (2) the maintenance of pregnancy; (3) th inhibition of oestrus in pregnancy; (4) the development o the breasts; it was improbable that one substance wa responsible for all these. The extract of the corpus luteun was very unsuccessful, clinically, as a substitute for the livin gland, yet experimental injections of the extract inhibite oestrus in animals. As a result of these observations i seemed highly probable that there were two secretions o the ovary—the oestrus-forming and the oestrus-inhibitin secretions; in this way the "oestrus-producing hormone" and the corpus luteum acted in opposition. Theoretically, therefore, an injection of the oestrus-forming hormone overriding the corpus luteum should bring about the ter mination of pregnancy, and, as a method of induction of labour, would be of great value clinically. The extracts of the corpus luteum on the other hand would provide a means of treating such conditions as persistent amenorrhoea, repeated miscarriages during pregnancy, and mammary insufficiency. It was doubtful whether any improvement in cases of infantile uterus would be obtained from administration of the oestrus-producing hormone. Experimentally, as a result of the injection, the infantile uterus underwent hypertrophy which appeared to be evanescent. Dr. Parkes demonstrated by slides the relative development of the Graafian follicles and corpora lutea during the menstrual cycle, and also showed that in mice ovariotomy before and after puberty produced deficient development in the organs and accessory organs of generation.

The CHAIRMAN said he had been disappointed in the clinical effects of the administration of ovarian extracts; he was unable to claim any success.

Professor BLAIR BELL considered that the histology of the ovary, uterus, and other organs of generation must be more fully considered, and that further study should be devoted to the ovary in regard to its local and metabolic actions. It was now well established that the corpus luteum persisted in cases of pseudocyesis. The interstitial cells of the ovary alone would keep the uterus "sexually active," as had been proved by the administration of x rays, which destroyed the superficial cells of the ovary, and therefore the follicles, leaving the interstitial cells.

Dr. BOURNE stated that he had used "oestrin" for the induction of labour on three occasions, administering doses of between 20 and 40 rat units, but with clinical results in only one case. He had also given this substance in a case of sterility with amenorrhoea. He looked forward to the day when ampoules of oestrin could be supplied in doses of over 40 rat units and its injection be made less painful. He was certain that much larger doses than 40 rat units would be needed to be of any clinical value. Until these problems were solved he was convinced that ovarian therapy would make but very slow progress.

Dr. PARKES, in reply, said he hoped the day was not far off when a water-soluble preparation would be on the market. Experiments had been performed upon goats, and it had been found that whereas a dose of 500 rat units produced abortion, 300 rat units injected into a larger animal did not do so.

Reviews.

EXOPHTHALMIC GOITRE.

THE trend of modern thought in regard to Graves's disease is reflected in Dr. JOHN EASON'S recently published book on *Exophthalmic Goitre*.[1] Ten years ago those who doubted the thyrogenic nature of this malady, or who affirmed that "the routine treatment of Graves's disease is not surgical," were in the minority. But in these later years this attitude of mind has spread, and to-day the measure of our independence of thyroidectomy is a fair measure of our advance in knowledge.

Dr. Eason's book is divided into two parts: The first is introductory and deals, in two chapters, with anatomical and physiological considerations and with the clinical examination of the thyroid gland, the last being excellently described. The second has one chapter on etiology, three on clinical features, and one each on diagnosis, pathogenesis, pathology, prognosis, and treatment; all very detailed. A list of selected references is given and an index is provided. Those who study this book—and it requires close study—will be impressed by the painstaking manner of its preparation, by the comprehensive way in which the subject is presented, and by the slow growth of new knowledge regarding the nature of that morbid product of modern life—exophthalmic goitre. "It is sometimes stated," Dr. Eason says, "that the etiology of the disease is unknown, yet the circumstances in which it develops are known with a remarkable definiteness in the majority of cases." Of these circumstances an inborn or acquired "diathesis" or "autonomic imbalance" is considered to be the chief. Given this peculiar habit of body in a person of the female sex, in the *period* of active sexual life, who is of "light skeletal *build*, with fine bones, narrow build, acute costal angle, small muscles, and poorly hung viscera," subject her to adequate excitation—unusual nervous strain, prolonged emotional disturbance or infection—and the stage is laid for the tragedy. "Why is it," the author asks, "that the gracile type has a special tendency to exophthalmic goitre, while others, equally exposed to exciting factors, are less liable according as they are more powerfully built and more masculine?" The reader may agree with Dr. Eason that this question goes to the root of the problem, but he will probably be more concerned to know the cause of the "inborn or acquired diathesis" or "autonomic imbalance" which predisposes to Graves's disease. "In proportion as the individual is originally nearer the folio edition of the genus homo (the A1 type) the adequate excitation must be greater and greater." Conversely, we may suppose, the nearer the individual is to the C3 type the less proof is she (or he) against exophthalmic goitre. Has the disease, then, a nutritional basis?

Dr. Eason does not say much regarding the underlying nutritional factors in its genesis; but what he does say calls to mind the remarkable effects of faulty nutrition on skeletal structure, on absorption and assimilation, on all endocrine organs, on the nervous tissues, on the reactions of the body fluids, and on susceptibility to infection—effects learnt by experiments on animals. Dr. Eason thinks that "observations made on animals regarding the thyroid provide no solid contribution to our knowledge of the etiology and pathogenesis of exophthalmic goitre"; but surely it is by observations on animals that we may learn more of the part played by the thyroid gland in the animal economy, more of its relation to the phenomena of nutrition, and more of the disturbances directly or indirectly induced in it, in its coadjutors and in the autonomic nervous system, by faulty nutrition. "The fundamental conception of exophthalmic goitre is," the author says, "that it is a disorder which is due to a kinetic vicious circle." Of exciting factors there are *many*, but "by a very long way first in importance are those that operate through the emotional centres of the brain." This view will be endorsed by many who have for long been of the same opinion. For there are few diseases in which "thick-coming fancies" do more to initiate and to maintain the sufferer's disabilities:

> "Cure her of that . . .
> Pluck from the memory a rooted sorrow,
> Raze out the written troubles of the brain,
> And with some sweet oblivious antidote
> Cleanse the stuff'd bosom of that perilous stuff
> Which weighs upon the heart?"

Dr. Eason keeps this aim prominently before his readers.

To those of us who are especially interested in the causation of this disease the last two pages (the appendix) will be amongst the most valuable in the book. If a sufficiently large number of cases of Graves's disease were accurately recorded, according to the scheme therein set out, and competently analysed by persons skilled in scientific method, our knowledge of the physiological mechanism—nervous and endocrine—of exophthalmic goitre would not long remain "so imperfect that the clinician cannot grapple satisfactorily with the problems of its origin and nature."

Dr. Eason's book should help to dissipate that "dormant attitude of mind of medical men in general," regarding the place of medicine in the routine treatment of this disease, about which Dr. Bram complained in the second edition of his book on *Goiter*.

MARIE'S COLLECTED PAPERS.

PROFESSOR PIERRE MARIE has decided to bring together a number of his literary productions and publish them in book form, and the first volume has recently appeared bearing the title *Travaux et Mémoires*.[2] The reason he gives in his preface for making this decision is that the original articles are distributed in weekly journals and reviews, many of which have now ceased to exist, or are to be found in but few libraries to-day. This, he states, simply means annihilation for these works, some of which may deserve to survive yet a time longer. Such is the modest view he takes of works which will probably ever be consulted in the first instance by all who enter on the study of the subjects with which they deal. The articles have lost none of their freshness through the lapse of years (the earliest was published in 1886), and can be read with as much interest now as at the time of their publication. The volumes will be a valued addition to our libraries. That now before us consists of two parts, the first containing the well known articles on aphasia, the second the descriptions of a number of diseases of the skeletal system which Marie was the first to recognize as distinct entities. The articles on aphasia take us back to the year 1906, when Marie the iconoclast, as Head has called him, published a paper on the revision of the question of aphasia, which shook the current theories of aphasia to their foundations. The conceptions then prevailing were characterized by such simplicity that they could be represented on charts somewhat resembling those indicating the stations on the tube railway. There was a definitely localized auditory word-centre, a visual word-centre, a motor centre for articulation, and another for the movements in writing; these centres were connected by intercommunicating and branch lines. In any given case of aphasia it was possible, by handling the clinical symptoms with a certain amount of freedom, to indicate the lesion on the chart and define the type of the aphasia. Marie swept all this away. He showed that a number of important symptoms had been left out of account in the current views on aphasia, and that the condition was not due to the suppression of this or that definitely localized function, but depended on a more general and, in particular, an intellectual defect. He so far retained the notion of localization that he referred aphasia to changes in the so-called area of Wernicke—the supramarginal, angular, and posterior ends of the first and second temporal gyri. Further, he separated anarthria—inability to speak—from aphasia, and located the changes producing it in and about the lenticular nucleus. Finally, he considered Broca's aphasia—that is, aphasia with inability to speak—to be a combination of anarthria and

[2] *Travaux et Mémoires*. Par Pierre Marie. Tome Premier. Paris: Masson et Cie. 1926. (Med. 8vo, pp. 358; illustrated. 35 fr.)

aphasia in the sense in which he used the latter term. Speaking generally, Marie cleared the ground of dogmas and left the way open for a study of the subject on psychological lines.

The second part of the book contains reprints of the well known articles on ''ophic pulmonary osteo-arthropathy, hereditary cleido-cranial dysostosis, and achondroplasia. All of these, with their excellent illustrations, are of enduring value.

PHYSIOLOGICAL AND PATHOLOGICAL CHEMISTRY.

Two parts of the first volume of Professor OTTO FÜRTH's textbook of physiological and pathological chemistry[3] have already been reviewed in these columns. Part III, completing the first volume, is now in our hands and allows us to extend to the whole volume the commendation we expressed of the earlier parts. The habit of issuing a large textbook as a serial has obvious advantages to both author and publisher, though its benefit to the reader is not apparent. Perhaps we may suspect in this policy a compromise by which the bookseller—that aristocrat amongst tradesmen—brings himself to engage in trade upon the instalment plan. The duty of the reviewer of an enterprise which must be seen whole to permit judicious appraisal is certainly rendered more difficult by such method of publication. The comprehensive character of the labour which Professor Fürth has undertaken and the admirable way in which he appears to be executing it forbids, however, our grudging him the small satisfaction of transferring now and again to the publisher the growing pile of manuscript on his desk.

The present part deals with the biochemistry of the main organs of internal secretion. The chapters are devoted to the male and female sex organs, the adrenals, the thyroid and parathyroid, and the pituitary. In addition, chapters are given to the subjects of fertilization and the development of the egg, to the mammary gland and the chemistry of milk, and to the biochemistry of malignant growths. An immense literature has been drawn upon, and the discussion is admirably up to date the while a reasonable critical faculty has been preserved. Part III of Volume I gives us no cause to qualify the welcome we have already extended to this work.

THE SEMILUNAR CARTILAGES OF THE KNEE.

UNDER the title of *Pathologie des Ménisques du Genou*,[4] Professor LOUIS TAVERNIER and Dr. ALBERT MOUCHET have written a monograph on internal derangement of the knee-joint, and have included in it a section on cysts of the fibro-cartilages. As the authors acknowledge, it is only of late years that the operative treatment of these lesions has received much attention in France or indeed in Germany, nor until in England a whole literature had grown up round it and thousands of cases had been successfully treated by surgical intervention. Therefore there is much more need and use for a work of this sort in France than there is in Great Britain.

The authors begin by a clear and well illustrated description of the normal anatomy of the joint and of the functions and action of the semilunar fibro-cartilages. In the passage on etiology we note with interest that, as regards sport, a distinction is made between "foot-ball" and "Rugby." The authors rightly state that injuries of the cartilage are by no means confined to the devotees of sport, and quote the statistics of Martin of Newcastle-on-Tyne to show its great frequency among miners. The pathological anatomy of the various lesions is well described and illustrated by clear drawings, which we think serve their purpose better than photographs; the latter are apt to be rather obscure when taken from such subjects, owing to lack of contrast. The authors are very sceptical as to the occurrence of what Roux of Lausanne has described as "traumatic meniscitis," and their caution is justifiable. They give reasons for doubting the correctness of the "Anglo-American" view that one of the chief causes of damage to the menisci is rotation of the leg on the thigh. They hold that extension alone can, and does, produce it, when there is friction or obstruction between the condyles of the femur and the fibro-cartilages. The operation of arthrotomy for the removal of a cartilage is clearly described and well illustrated. The line of incision recommended is transverse, and in the usual case of the internal cartilage it involves section of the internal lateral ligament, sacrificing perhaps subsequent security of the joint to freedom of access and width of view. If we read them aright a similar division of the external ligament is recommended in the case of the outer cartilage, but the tendon of the biceps is to be respected.

The last few pages are devoted to the subject of cysts of the cartilages, which are almost always the result of injury and situated on the outer side of the joint. There is a full bibliography, but no index.

CANCER OF THE BREAST.

No one, says Professor DELBET in his work on cancer of the breast,[5] would think of treating a cancer of the skin without taking into consideration the histological type of the growth. Cancers of the breast exhibit differences of type which are just as marked, and yet Professor Delbet says it is the custom to regard them as if they were all of the same species. With a view to correct this inconsistency he has passed under review all the preparations of tumours of the breast in his laboratory, has traced the after-histories of the patients as far as possible, and has found that certain histological characters, noted without any preconceived ideas, appear to be related to a definite course of the disease. He considers that histology enables the prognosis to be made in many cases, and that some growths can be shown to be relatively benign Keeping in view the prognostic significance of the histology, he has adopted a classification which does not pretend to be strictly systematic and which has a threefold basis—namely, the morphological characters, the physiological characters, and the tendency to invasion of the blood vessels. Eight morphological classes are distinguished, depending on variations in the characters of the cells—namely, (1) cubo-cylindrical, (2) squamous, (3) polymorphous of mammary type, (4) polymorphous of ectodermal type, (5) clear cell type, (6) cytolytic type, (7) isolated cell type, and (8) giant cell type. The first of these is further subdivided according as the cells are arranged in pseudo-acini within the cell mass, in definite acini bounded by connective tissue, in the form of tubules, as papillary ingrowths, or on the type of a perithelioma. The clear cell type is said to resemble in every detail the so-called hypernephroma; the cytolytic type is characterized by a liquefactive disintegration of the periphery of the cytoplasm, which is attributed, not to degeneration, but to a particular form of evolution of the cell; in the isolated cell type the cells show no tendency to stick together, a feature which is said to favour their dissemination; in the giant cell type the cells are of great size and, in the zone of invasion, often multinucleated. With regard to prognosis the authors are able to state that growths of the cubo-cylindrical type with pseudo-acini are relatively benign, the same being true also of the clear cell type. On the other hand, the large cell type is extremely malignant.

The physiological classification is based on the visible secretion of the cells. Three classes are recognized, one exhibiting an albuminous, the second a mucous, and the third a mixed muco-albuminous secretion. The mucous type is held to indicate a certain degree of benignity, and when occurring in association with a malignant morphological type, the authors consider that the malignity is reduced.

Delbet has given his third class of tumours the not very convenient name of haemophilic cancers. In these the tumour cells exhibit a special affinity towards the blood

s, and histologically the growths are characterized
e presence of tumour cells within the lumen of the
ls. This type is met with in any of the morphological
before mentioned, and is shown by statistics to be of
itely malignant significance.

are indebted to Professor Delbet and his collaborator
ARD for a valuable addition to our knowledge of the
logical anatomy and prognosis of cancer of the breast.

COLLOIDAL REACTIONS OF THE CEREBRO-SPINAL FLUID.

main interest of the book M. EUGÈNE DE THURZO has
en on the colloidal reactions of the cerebro-spinal
lies in the suggested modifications in the technique
e familiar gum benzoin, mastic, and colloidal gold
By the introduction of suitable dyes into the re-
s employed the author has found it possible to develop
ducible colour changes accompanying the turbidity
precipitation changes in the tests. In this way he
been able to differentiate ten degrees of reaction
e tests of the cerebro-spinal fluid at varying dilution.
author discusses from his own experience the relative
tivities and specificities of the original tests and their
fications in a number of diseases of the nervous system.
value of the paraffin reaction of Kafka and the shellac
is also reviewed. There is included a description of
ges in the colloidal reactions which were found to
mpany neosalvarsan treatment of syphilis of the
ous system.

the author acknowledges, the colloidal reactions of
erebro-spinal fluid are essentially empirical, and there-
all systematic studies of their diagnostic reliability
f value to those whose business it is to exploit them.

NOTES ON BOOKS.

first edition of Professor STEVENS'S *Practice of Medicine*[7]
ared in 1922, and has been widely appreciated. A second
on has recently been published. The articles dealing
syphilis of the circulatory system, botulism, heliotherapy,
tes mellitus, alkalosis, spasm of the œsophagus, chronic
ative colitis, multiple polyposis of the intestine, jaundice,
rcardia, paroxysmal tachycardia, arterial hypotension,
ary purpura haemorrhagica, erythraemia, haemorrhagic
ses of the newborn, trigeminal neuralgia, and tumours
he cauda equina have been rewritten. Amongst the
ses not described in the former edition, but now included,
primary meningococcic bacteriaemia, disseminated cry-
atous lupus, tularaemia, lipodystrophy, agranulocytic
ia, uveoparotid fever, vasomotor rhinitis, Epstein's
rosis, Ayerza's disease, chronic sclerosing osteitis, acro-
a, and Horner's syndrome; among the new articles is
on the etiology of scarlet fever and the Dick test for
mining susceptibility to scarlet fever. Dr. Stevens has
eeded in giving a succinct presentation of the various
nal diseases, and in these days of increasing specialization
g to the rapid advance of medical science on all fronts,
is no light task. His book is well adapted to the needs
the student and the general practitioner. Numerous
ences are quoted, and wherever we have sampled its
minous contents and checked the references given in Dr.
ens's work, we have found evidence of a wide and accurate
ledge of recent medical literature and a wealth of clinical
rience.

he *De Lamar Lectures*, founded in 1920 and now adminis-
l by the School of Hygiene and Public Health at the Johns
kins University, are intended to inform the public on the
ention of disease and on personal hygiene. The volume of
thirteen lectures given in 1925-26[8] begins with the preven-
of simple goitre by Dr. David Marine, director of labora-
s at the Montefiore Hospital, New York. Dr. Alice Hamilton,
king on industrial toxicology, reviews the important work
has been done in the United States during the last fifteen
years. Dr. E. R. Baldwin, director of the E., L. Trudeau Foundation, Saranac, sets out the absolute and relative values of laboratory procedures in the diagnosis of tuberculosis, and refers to the charlatan "curing an incurable disease that did not exist." Dr. H. LoGrasso describes the treatment at Leysin, paying a tribute to "the father of heliotherapy," Dr. A. Rollier, and compares with it the practice at the J. N. Adam Memorial Hospital, Perrysburg, N.Y., where he works. Dr. J. Goldberger of the United States Public Health Service discusses the nature of the dietary deficiency responsible for pellagra, and Professor C. R. Stockard the relation to disease of type, which he defines as a fixed characteristic, and of constitution, which may change several times in the life of the individual. The volume closes with Sir Arthur Newsholme's account of William Farr, whom he calls "the father of vital statistics," just as Louis, who exerted a considerable influence on Farr, may be regarded as "the father of medical statistics."

Although described on the cover and in the advertisements as a textbook for students of agriculture and veterinary science, the scope of *The Physiology of Reproduction in the Cow*[9] is more aptly referred to in the preface as a reference book for advanced students and practitioners in agriculture and veterinary science—a very different thing. It contains a detailed account of all pertaining to reproduction in an animal which owes its supreme importance solely to that function. The author has based his studies on experimental animals, on organs collected from slaughterhouses, and on answers returned by experienced stockmen and others engaged in breeding cows, to questions addressed to them; in addition, he has examined the literature on the subject. His monograph falls into four parts: the breeding season and the age of puberty; the oestrous cycle, its periodicity and rhythm, its duration and the changes which occur; pregnancy and the alterations in the various organs; and sterility. These four divisions are extremely well illustrated in thirty-three excellent half-tone or coloured plates. A bibliography and a comprehensive index are provided, but unfortunately the former is arranged on the irritating numerical system instead of the more convenient alphabetical manner. This is corrected to a certain extent by a list of authors, but as the reference is only to the text it necessitates a double reference. The monograph is a mass of detailed information critically considered, and although knowledge of this subject is still far from complete, it is as comprehensive as present-day information can make it. It will be invaluable to all interested in reproduction, not only in the cow, but in all other animals.

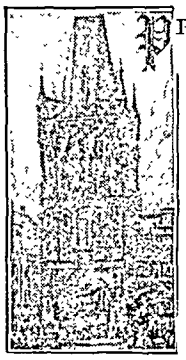
PREPARATIONS AND APPLIANCES.

An Electric-heated Radium Wax-knife.

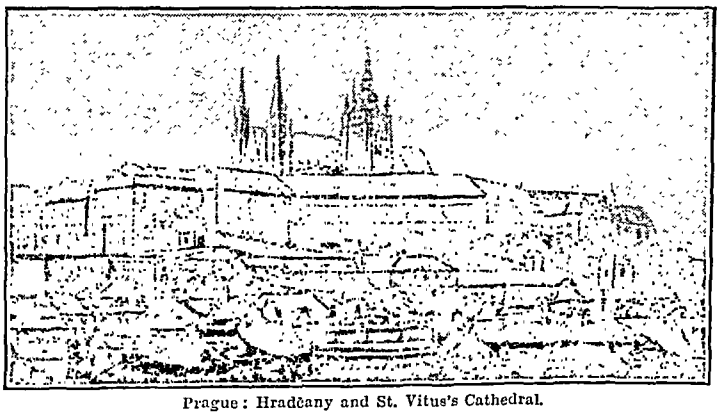


MR. ARTHUR B. SMITH, M.B., F.R.C.S.Ed., and Dr. SYDNEY M. SMITH (London, W.), write: Radium when applied at a distance from the skin in inoperable and post-operative cancer, according to the principles of Regaud of Paris and other continental workers, is supported by means of wax moulds fitting over the part. The construction of these involves considerable manipulation and the electric wax-knife has been designed to facilitate

this. Repeated heating of an ordinary wax-knife is both tedious and unsatisfactory. The wax-knife is kept constantly hot by means of an electrical resistance surrounding the upper part of the blade. The current (240 volts) is obtained from the ordinary room supply through an insulated wire with socket. The illustration shows the instrument in use. It can be obtained from the Medical Supply Association, 167, Gray's Inn Road, London, W.C.1.

THE SPAS OF CZECHOSLOVAKIA.

A MEDICAL VISIT TO PRAGUE.*



Prague: The Powder Tower.

PRAGUE, though not a spa, may fairly be counted a health resort if refreshment of the eye and spirit plays any part in healing. Once *Praha*, then for long *Prag*, and now again *Praha*, this remarkable city has been for a thousand years the hub of the political and intellectual life of the Czechs; and in its stones, as the phrase goes, may be read the history of a nation. Since the Treaty of Versailles the ancient capital of the Bohemian kingdom has been the capital of the group of central European States (Bohemia, Moravia, Slovakia, Silesia, and Ruthenia) known as the Republic of Czechoslovakia, founded on the ruins of the old Austro-Hungarian Empire.

Before 1919 the existence of a Czech nation, with a burning sense of nationality, was scarcely known to the people of the British Isles. It is still too little known here, although Czechoslovakia, with an area as large as England and Wales, has now some fourteen million inhabitants (of whom rather less than a quarter are German), and is an industrious, progressive, and interesting country, well worth a long visit.

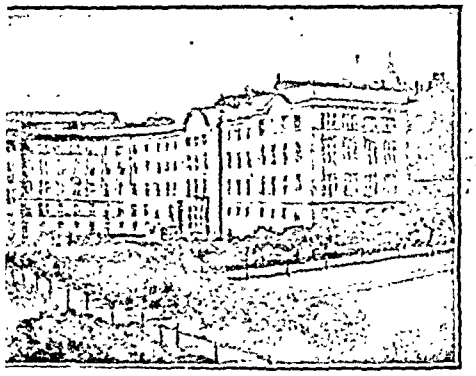
Prague, one of the most enchanting mediaeval towns of Europe, has grown much since the nation gained its freedom, and its population must now be nearly 700,000. It lies in the middle of old Bohemia and forms a point of intersection for the railways between most of the capitals of Europe. Like Rome, it is a city built on hills and washed by a broad river; and the skyline of Prague, with its hundred spires, is incomparable. The dominant note is the stone pile of the great castle on Hradčany hill, for centuries the seat of Kings of Bohemia and now the official residence of the President of the Republic. Above the Castle rises the cathedral of St. Vitus, its interior to-day a forest of scaffolding. Hradčany in spring sunshine, seen from the Belvedere on an opposite hill, is a thing never to be forgotten. As for the other sights of the city, old and new—the ancient town square, the bridges and gateways and arcades, the mediaeval ghetto graveyard, the queer narrow lanes leading out of broad modern thoroughfares—there is no space here even to name them, and we must pass on to some institutions having links with medicine.

Prague: Hradčany and St. Vitus's Cathedral.

The University, founded in 1348 to the pattern of Bologna and Paris, played a great part in the history of Bohemia during the Hussite Wars. Then after the battle of the White Mountains, where the Czechs lost their independence in 1620, it fell into a long decline. For many years all efforts to develop medical science in Bohemia on large lines were (*to put it mildly*) discouraged by the Government at Vienna; but the work of the Czech Medical Society of Prague since 1860 has not been thrown away, and already there are signs of great progress in all branches of medicine and the ancillary sciences. The outstanding event in the half-century before the war was the re-establishment in 1882 of a purely Czech University with a medical faculty, and the founding beside it in the capital of a separate German university. The beginnings, however, were difficult, and much material had to be got together. Since the war the Czech or Charles University of Prague has regained its old standing, two new Czech universities have been founded (at Brno and at Bratislava), and one after another new professional and scientific societies have *sprung up*.† The numbers of medical students at Prague have been very large indeed in recent years, but, to the relief of the teachers and university officials, there is now some abatement of the flood.

While the medical profession of Czechoslovakia, and in particular their leaders and teachers, desire a national science of their own, they desire also to maintain and strengthen contact with the larger world of medicine outside; and, like so many of their race, they seem to turn instinctively towards our country. Many of them read and speak English, and, in Prague and the Spas at least, there are plenty of doctors with a good command of our language and a wish to know more of ourselves and our work. Such certainly was the conclusion reached by the party of British physicians who lately toured the health resorts of Czechoslovakia, and got to know something at first hand of its medical men and medical institutions.

During the short three days spent in Prague many courtesies were extended to the visitors. They were met on their arrival from Marienbad by representatives of the Czech Government, of the municipality, and of the medical world of the capital. On the following day a luxurious tramcar was put at their *disposal for* a tour of the city under the guidance of an official who evidently knew and loved the things he showed. They were most graciously received at the Town Hall by the Burgomaster and chief officials of the city, and in the evening were entertained to a banquet given in their honour at the Spolecensky Club by the Minister of Public Health and Physical Education. The Minister—a clerical statesman, the Rev. Jan Sramek—himself presided, and the British Chargé d'Affaires, Mr. C. E. S. Dodd, was present, together with officials of the Ministry and leaders of the medical profession in Prague.



After the flying visit to Poděbrady, recorded below, an excursion was made on April 23rd to the sanatorium for paying patients at Prague, to the University Hospital, and to a few of the scientific departments of the University; a long afternoon ending with tea as the guests of Mr. and Mrs. Dodd at the British Legation, whose garden, under the shadow of Hradčany, offers exquisite views of the city.

The Prague Sanatorium for *paying patients* is on the river embankment towards the outskirts of the city, and a steep cliff rises behind. It is in many ways a remarkable institution, unlike anything in this country. All the departments—*obstetrical*, surgical, radiological, etc.—are self-contained, with operating theatres of the most modern type, and well equipped laboratories. The wards, large and small, are comfortable, and from many windows there are fine prospects over the river. Everything in this

* An earlier note, on the spas of Western Bohemia, appeared in the BRITISH MEDICAL JOURNAL of May 14th, p. 885.

† See BRITISH MEDICAL JOURNAL, July 3rd, 1926, p. 28, The Renaissance of Medicine in Czecho-Slovakia, and February 26th, 1927, p. 356, Czecho-Slovak Medicine.

other scientific departments of the two Prague ies. The laboratories, lecture theatres, research ınd museum are excellent. Time only allowed ed glance with Dr. Kotynek as guide, but all pressed with what they saw, and in particular really palatial "pathological dissecting room"— ofty, odourless, and as open to daylight as a tory.

the most striking features of the Prague Medical f to-day (and by this we mean material, outward only) is the Czech Embryological Institute, opened r by the revered President of the Republic, Pro- omas Masaryk, whose portrait hangs in a place of This is a magnificent building, on a very large

scale, and (at least to the casual visitor) it seems "the last word" in laboratory construction and equipment. The largest lecture-room—known as the *Amphitheatre of* Purkyně in memory of the great Czech physiologist we call Purkinje—will seat 330 students in comfort. The microscopical room occupies one floor of a large bay, whose lofty windows are seen on the right of the snapshot taken by Dr. V. G. Ward of West Byfleet, a member of the party. This laboratory, like everything else in the institute, is remarkable for the bold simplicity of its propor-

Prague: Embryological Institute.

tions and the perfection of its fittings; it accommodates 75 students working at three tiers of semicircular benches. Much space is set apart in the same wing for the culture of living tissues, a branch of research in which Dr. Vladimír Tuma (who showed the party round) has kept close touch with the work done at Cambridge by the late T. S. P. Strangeways and his colleagues. The Institute possesses also an ample radiographic department and a fine collection of transparent tissue specimens. Nothing, in short, has been stinted anywhere, and the lavishness of it all suggests that the Government and the Charles University agreed together that this, and the adjoining but as yet uncompleted building, should be the best of their kind without regard to cost. A medical school, however, is not to be judged by its classrooms alone, but by the spirit in which its work is done. At Prague, we believe, the imponderables are not valued below bricks and mortar.

The Baths of Poděbrady.

Poděbrady, some thirty miles east of Prague, is a little town 600 feet above sea-level, in the broad flat basin of the Elbe. Its small bathing establishment, then known as "The Baths of the Prince of Hohenlohe," was bought in 1910 by the municipality, which sank a number of new wells and added to the buildings. In 1919 the enterprise was taken over by a company and further extensions followed. Thus the watering-place of twenty years ago, too insignificant for mention in Weber's *Climatotherapy and Balneotherapy*, has grown into a spa of some standing in a country of spas, and its nearness to the capital brings many visitors in search of health or recreation.

The baths are comfortable and well equipped. The water of fifteen springs is well charged with natural CO_2, and pleasant to take both within and without. It is bottled at the source, and great quantities go to all parts of the country. For a spa of this size the scientific equipment of the baths is very complete, and the physicians

take pride in their radiological apparatus, their electro-cardiograph, and their careful case notes.

The medical party from England went there on the first spring day of their tour, when the early green on the trees gave a hint of the charm of Poděbrady in summer costume. This, with the genuine warmth of their welcome by the townspeople, and the glowing speeches they heard, makes April 22nd, 1927, stand out as a day by itself. Over a gateway in the ancient castle of the Bohemian hero, King George of Poděbrad, they were shown by their friend Dr. Driml two stone scutcheons epitomizing the story of a nation in bondage; and from Mr. Sustr, the pastor of the town, they learnt that Poděbrady, "the heart of Bohemia," feels something more than friendship for the people of our distant islands, whose entry into the war gave it hope of freedom.

Our illustration, from a water-colour drawing, shows part of the old market-place of Poděbrady, near the modern pump-room with its gay terraces and gardens, and the castle tower in the background.

(To be continued.)

THE HEALTH OF THE NAVY.

REPORT FOR THE YEAR 1924.

A CONSIDERABLE lapse of time continues to be the rule between the publication of the annual reports on the health of the navy and the year to which they refer. In this respect they contrast unfavourably with the reports on the health of the army and air force. The report for the year 1924, just issued, presents us with the health statistics of a total force of 87,620, and of its component parts in the different fleets and stations.

The ratio of admissions to the sick list for the total force was 486.24 per 1,000. This is somewhat higher than the ratio for 1923, but 56.15 lower than the average ratio of the three years 1921-23. The number constantly sick was 22.18 per 1,000, and the death rate 3.09. The death rate in the previous year was only 2.17 per 1,000, but the average for 1921-23 was slightly higher (3.11) than in 1924. Deaths were somewhat equally divided amongst diseases (1.78 per 1,000) and injuries (1.31 per 1,000 of strength).

Amongst the diseases causing admission, 759 are recorded as cases of cow-pox, of which 713 occurred in home stations, chiefly in the training establishments and depots. They represent men temporarily unfit for duty after vaccination. A table is given showing the numbers vaccinated or revaccinated with Government lymph and with lymph from other sources, with the corresponding successes and failures. Although revaccination successes are considerably less with lymph from other sources, the circumstances in which, and the stations where, this lymph was used are not mentioned, and the statistics cannot therefore be regarded as of much value in comparing the two sources of the lymph used in the navy, when it is remembered how easily the efficiency of lymph is affected by storage and climate.

The chief causes of admission to the sick list were injuries (7,637 cases), venereal diseases (7,172), diseases of the digestive system (6,665), of the respiratory system (6,398), and of the areolar tissue and skin (4,795). Amongst the infectious diseases influenza, with 2,407 cases, heads the list. Other infectious diseases and such semi-tropical diseases as dysentery, enteric fever, Mediterranean and sandfly fever, contribute comparatively few cases, although they do not show any marked increase or decrease as compared with the average for the previous three years. The bulk of the influenza cases occurred in the Home and Atlantic fleets, and we are told that the usual prophylactic measures, such as voluntary inoculation, avoidance of overcrowding, antiseptic throat spraying, disinfection of living spaces, attention to ventilation, and airing of bedding, were carried out. An outbreak of enteric fever is noted on the *Royal Sovereign*, but the number of cases is not stated, nor are we given other details beyond the statement that it was attributed by a court of inquiry to lettuces taken on board at Madeira contrary to the rules and regulations in force. In this respect the report as a whole is not illuminating, for it conveys little more than statistical statements and comparisons with 1923 and the average for 1921-23. We are given, for example, little or nothing as regards details of preventive measures. This is specially to be regretted, so far as venereal diseases are concerned, in view of the measures taken and recorded in the reports on the health of the British Army and on the health of the United States Army and Navy.

The report on invaliding is, however, more detailed. The number invalided, including men temporarily invalided from foreign stations, was 1,642, or 18.74 per 1,000. The number finally invalided from the service was 1,272, or 14.51 per 1,000—a decrease of 1.57 and 5.62 respectively on 1923 and the average of the previous three years. The chief causes of invaliding were sequelae of gonorrhoeal infection (209 cases), diseases of the eye (174), tuberculosis (166), and diseases of the ear (116). Thirty-one men were discharged the service for refusing surgical operations, chiefly for hernia, and for disease of the teeth and ears. A detailed table of each disease and injury causing invaliding, and the numbers invalided for each at different ages and years of service, is included in the report, but as the strength at each age and year of service is not recorded the figures do not indicate much that is of value statistically.

More than half the volume consists of statistical tables of individual diseases, showing numbers admitted, invalided, and died, with their ratios per 1,000 of strength in 1924 and the previous three years' average, both for the total force and for each of its component parts in the different fleets and stations. Other statistical tables included in the report show the complements of each ship in the Royal Navy, according to station and period in the station, the number of cases of sickness and injuries on each, and the number sent to hospitals on shore. Statistical tables are also given showing the health statistics of the Royal Marines headquarters, of boys and youths in the training establishments, of officers and men in the Royal Navy depots, and of dockyard establishments and Royal Marine divisions. There are also tables of cases admitted to the R.N. Mental Hospital at Great Yarmouth and other R.N. hospitals at home and abroad.

Valuable as these statistical records are for comparing the health of the navy in one year with another or with a period of years, we feel confident that something more than a bare statistical statement of the principal diseases—something, that is to say, similar to what we have been accustomed to in recent reports on the health of the army—would add greatly to the medical and public interest of the annual report on the health of the Royal Navy.

Nova et Vetera.

AN ACTION FOR DAMAGES FOR MALPRAXIS.

THE following entry, relating to an action for damages against a surgeon, appears among the early Chancery proceedings (undated, *circ.* 1435) in *Select Cases in Chancery*, edited for the Selden Society by William Paley Baildon (1896):

> "To the most gracious lord, the Chancellor of England, Humbley beseecheth your poor orator, Ralph Fryday, that whereas the suppliant's right arm was broken through certain evil-doers, who lay in wait to kill him, which arm, one John West of Leicester undertook at Wigston well and duly to cure and save; which John set about his cure of the said arm so improperly, through the malice and covin of the enemies of the said suppliant, that the arm mortified and became incurable, to the perpetual destruction of the said suppliant: May it please your most gracious Lordship to grant the said suppliant a writ directed to the said John West (commanding him) to appear before you in the Chancery on the octave of the Purification of our Lady under pain of £40 to be examined by the surgeons of our Lord the King, and by other efficient surgeons, as to that cure not duly performed, and also to answer to the said suppliant for this great injury, as right and reason demand, for God and in the way of charity. Considering, most gracious Lord, that the said suppliant cannot have execution nor any remedy at (common) law for this misdeed so done by colour of the cure, if he be not aided in this way, because of the great maintenance against the said suppliant in those parts."

The original is in French. The editor in his introduction says: The singular case against the surgeon is chiefly interesting from the fact that the plaintiff asks for the King's surgeons and other sufficient surgeons to be called as expert witnesses. Apparently both trespass and assumpsit lay at common law in such cases. A case in 1443 was one of a broken leg, which the defendant, described as a "leche," had undertaken to cure in consideration of 40s. The leg mortified, in consequence of the surgeon's neglect according to the plaintiff, or because of the patient's wilful disregard of directions according to the defendant. The case went to a jury, but the judgement has not been found.

Another case of a similar nature, between 1492 and 1500, will be found in the Calendar (cxxiv). The plaintiff is a surgeon. The defendant's child was "diseased in the ei wt a pynne and a webbe"; he requested the plaintiff to cure it. The plaintiff undertook to do so if the defendant would see that the child did not touch or rub it; this was not done, and the plaintiff was unable to save the eye. The defendant thereupon brought an action of trespass before the Sheriffs of London. The plaintiff prays for a certiorari.

British Medical Journal.

SATURDAY, MAY 28TH, 1927.

THE DETERMINATION OF SEX.

rm. not very long ago it was generally understood at at the time of fertilization the egg was completely ibivalent as regards the future sex-organization of e resulting individual, and it was customary to refer e sex of an organism to the conditions incident to velopment. But certain facts of general biology are w established which are not susceptible to interetation of this kind: they point directly to the nclusion that sex in the higher animals is determined at the time of fertilization by the precise rkings of an orderly mechanism. It is established at identical twins, derived from one and the same um, are always of the same sex and remarkably ke, whereas fraternal twins, having their origin in o separate ova, may or may not be of the same sex, d are no more alike than are brothers and sisters rn at different times. There is no appreciable ason why, if purely environmental factors are at ork in deciding the sex of offspring, identical twins ould be of the same sex, whilst fraternal twins ould include both male and female. The evidence twinning points to the conclusion that the sex of e future individual is determined at the time of rtilization by the constitution of the fertilized egg.

The mode of transmission from generation to generaon of certain characters (details of structure or of nction) is such as very strongly to suggest that the echanism by which they are distributed is either the me as, or else is closely associated with, that by hich sex itself is determined. Such characters are own as sex-linked, and of these haemophilia, as hibited by most cases, is an excellent example. The served facts concerning the transmission of haemoilia can only be interpreted if certain assumptions e made. The first is that sex in man is decided by e simplex or duplex condition of a component of me mechanism which, being present in duplicate, ads to the establishment of femaleness, and that on this component are the antecedent determiners the sex-linked characters. If search is next made r this sex-determining mechanism it is found in man at structural and physiological differences which stinguish the sexes are associated with constant fferences in the chromosome content of the comnent cells of the two sexes. Man has twenty-four airs of homologous chromosomes. In the somatic lls and immature gametes of the male one of the venty-four pairs (the allosome) is remarkable in that s constituent members are morphologically dismilar, whereas in the female the members of this air are, as is the case in all other pairs in both male nd female, morphologically alike (autosomes). Since ssues from male and female differ chromosomally aly in this respect, these chromosomes are referred o as the sex-chromosomes. The members of the ex-chromosome pair in the female and the one sexhromosome in the male which is morphologically milar to these are known as the X-chromosomes, hile the unequal mate of the X-chromosome in the ale is known as the Y-chromosome. The chromoome constitution of the male is 23 pairs of autosomes +XY; that of the female is 23+XX. Into each ripe gamete there passes one or other of each pair of homologous chromosomes. All ova, therefore, will be alike in the matter of chromosome constitution, twenty-four single chromosomes, of which one is an X; of the spermatozoa, however, there will be two kinds, according to whether they contain 23+X or 23+Y. As far as the chromosome content of the gametes is concerned, the human female is monogametic, the male digametic. When ovum meets sperm in fertilization each gamete will convey into the zygote one member of each pair of homologous chromosomes, and the specific number will be restored; but there will be two kinds of zygote—one which received an X-chromosome by way of the sperm, and the other which received a Y-chromosome. The first will have the chromosome constitution typical of a female, 23 pairs of autosomes +XX; the second that characteristic of the male, 23+XY.

If the antecedent determiners (the factors or genes) of sex-linked hereditary characters are borne in the X-chromosome, but not in the Y—and this suggestion is not extravagant, since in many of the domesticated animals there is no Y, the female being XX, the male XO—then the peculiar and significant mode of transmission of these characters is explained. Sex-linked characters are associated with the sex-determining mechanism (the XX-XY sex-chromosome mechanism), because their factors are located in the X-chromosome. This cytological difference between the two kinds of spermatozoa is reflected in a sperm dimorphism, estimated by measuring the head length. It has been found in a considerable number of species that there are two intergrading size classes, and it is assumed that the individuals of the larger class are those spermatozoa which carry the X-chromosome. This sex-chromosome sex-determining mechanism is such that, if the X-bearing spermatozoa are produced in equal numbers and are equally capable of fertilizing the ovum, then equal numbers of males and females will be conceived. By its working, sex is determined at the time of fertilization. The suggestion that femaleness is decided by the presence of the X-chromosome in duplicate, whereas maleness is determined by a single X, is but an essay in convenient symbolism. It is, however, reasonable to assume that the effective factor in the establishment of maleness or of femaleness is the ratio of X-chromosomes to autosomes. It is helpful to assume that in the X-chromosomes are female-determining factors which elaborate enzyme-like "gynase," and that on the autosomes there are [illegible] factors elaborating "andrase," and [illegible] of the zygote is determined by the balance between these. If A be taken to represent one complete set (haploid) of autosomes, then the relationship of sex-chromosomes to autosomes in the male can be symbolized as 1X:2A, whereas in the female it is 1X:1A. As the result of this interaction of male and female determining factors, elaborating their andrase and gynase respectively, it can be assumed that there becomes established one of two physiological states (metabolic levels) in the fertilized egg. In the 1X:2A type there is an internal environment of "maleness"; in the 1X:1A type one of femaleness; and in one or the other, as the case may be, organogeny and ontogeny proceed.

It is assumed from the results of experiment that the relative rates of production of the male and female differentiating substances elaborated by these sex-determining factors are not constant throughout life, that at one time one may be in efficient excess, and

at another the other. In the normal male the male-differentiating reactions are in efficient excess throughout the whole period of differentiation, but intersexuality occurs when during the course of differentiation of an individual of either sex, XX or XY, the male-differentiating reactions overtake and supplant the female-differentiating reactions, or the female the male. A male is a male because in his beginning he was a genetic male (XY), because in this XY zygote the relation of sex-chromosomes to autosomes, 1X : 2A, was such that an internal environment of maleness became established and persisted throughout the phase of differentiation, because in this environment the structures concerned in the sexual organization, also being genetically male, flourished, and because, as the gonads became differentiated, their internal secretions reinforced the initial maleness of the internal environment, and so directed the further development of the structures of the sex-equipment that, in the end, the individual became a functional male. "A female is a female by the totality of her internal secretions" remains true only if it be granted that the phrase "internal secretion" shall include the metabolic products of her initial sex-determining hereditary factor complex.

It will be noted that according to this chromosome theory of sex-determination (which is now generally accepted) the male, in the case of mankind, is the digametic sex, elaborating in respect of the elements of the sex-determining mechanism two kinds of sperm, the one which, when it fertilizes any egg, will yield males, and the other which will give females. It is not surprising, therefore, that the hypothesis, originally promulgated by Hippocrates and recently adumbrated by a cloud of witnesses, which postulates that it is the female who is digametic, meets with little support from present-day biologists. The variations of this hypothesis which are now advocated as leading to the control of sex, and which require that there shall be a difference in the kinds of ova elaborated by the right and left ovaries, are not such as can be brought into harmony with established scientific facts, and therefore cannot be accepted on the present evidence. They are supported by a collection of selected statistical data applied without statistical treatment; those cases which do not fit into the scheme are airily dismissed, while the great body of established facts which supports this chromosome theory and cannot support the others is neglected. This is not the attitude of the scientific mind.

The fact that there are the two forms of spermatozoa permits it to be postulated that if these are not elaborated in equal numbers, or if chemical or mechanical hindrances to their vitality or motility exist in the female passages so that one form is more severely handicapped in its race towards the ovum than the other, there will result a conceptional ratio of significant inequality. Recent work in this field has revealed a considerable amount of evidence which seems to show that the primary sex-ratio is far removed from equality, that under the usual conditions the X-bearing sperm is not nearly so efficient a fertilizing agent as is the Y-bearing, and that it is the high pre-natal death rate among the less viable XY zygotes that yields a secondary sex-ratio (at birth) of equality. There is good reason for the belief that an increase in our knowledge of the chemistry of the secretions of the female passages and of the effects of chemical and physical agencies upon the viability and motility of the sperm, may make it possible, to a greater or lesser extent, to control the sex of the offspring. Whether the use of this power would be to the benefit of mankind is a matter which need not now be discussed; but it would seem to be desirable that such power should be added to the armamentarium of the physician, who must be trusted to use it with discretion.

PERITONEAL ADHESIONS.

PERITONEAL adhesions, particularly those which recur in spite of operations, are a subject of anxiety to all concerned, and it is therefore interesting to gather the conclusions of Drs. F. Trémolières, physician, L. Joulia, radiologist, and H. R. Olivier, intern, of the Boucicaut Hospital, Paris, who have made a systematic investigation of abdominal perivisceral adhesions,[1] relying on radiology as the only means of localizing their position. It has commonly been assumed that these adhesions are secondary to some lesion of the intra-abdominal contents, but the authors accept the view that some cases are primary and independent of any change in the viscera, and hold that the most likely cause is either tuberculosis or syphilis. They admit that this is difficult to prove, but state that the obstinately relapsing cases and those prone to develop adhesions after laparotomy are often the subjects of congenital syphilis. Malaria, influenza, and acute rheumatism may also possibly set up these adhesions. For the secondary forms of adhesions four causes are given: inflammatory or infective, traumatic, congenital, and mechanical. Injury may act by causing a haematoma or by activating latent infection; post-operative adhesions, of course, come in this category. The congenital group includes Jackson's membrane, and here abnormal development rather than foetal peritonitis seems to be the important factor. The mechanical origin advanced by Sir Arbuthnot Lane is cautiously dismissed by the statement that, while unable to bring forward any arguments against it, they cannot find any clinical or experimental evidence in its support. In the section on morbid anatomy the various segments of the alimentary canal from the stomach to the sigmoid colon are considered in order. Investigation of the little known subject of the histology of peritoneal adhesions shows that there is under the endothelial layer, which is destroyed in places, fully developed connective tissue rich in collagen and poor in fixed cells; and that there may be foci of subacute inflammation and infiltration with lymphocytes and plasma cells. The omentum shows the same changes, with in addition atrophy of the fat cells and elastic tissue. Jackson's membrane and Lane's band show normal endothelium and blood vessels, and well formed fibrous tissue free from infiltration by lymphocytes.

The clinical symptoms vary according to the position of the adhesions and of the resulting or causal visceral lesions; they are described under six heads. Those caused by gastro-duodenal lesions usually imitate peptic ulcer, but sometimes gastro-colic ptosis. The typhlo-colic form, or painful dilatation of the caecum, often follows appendicectomy attended by only temporary improvement; it simulates chronic appendicitis with constipation—false appendicitis. In the entero-colic form there is diffuse colic with constipation; biliary pain may be due to pericolitis associated with cholelithiasis (true lithiatic), or to perivisceritis without any lesion of the gall bladder (the false form of lithiasis). The pseudo-neoplastic category includes two

[1] *Rev. de méd.*, Paris, 1926, 701-737.

forms. One is the rare inflammatory tumours in the right iliac fossa, which occur chiefly in old persons, and, in the absence of evidence of tuberculosis and syphilis, suggest carcinoma; the other form is the relatively common chronic sigmoido-perisigmoiditis which has often led to a diagnosis of carcinoma. In the obstructive form adhesions long latent may suddenly cause acute obstruction. The radiological appearances are fully described, and this part of the essay is illustrated by a number of skiagrams. The treatment may be medical or surgical; the former includes the administration of castor oil in small doses, or of paraffin; diathermy may be useful, as also sour milk and a milk and vegetable diet. Surgical treatment should aim above all at prevention, such as excision of any inflamed areas in the omentum; in long-standing cases demanding operation, during which adhesions are divided, the exposed surfaces thus produced should be covered by grafts from the omentum, which, contrary to what might be expected, are not likely to lead to the formation of fresh adhesions. Any focus, such as an inflamed appendix, should of course be removed at the same time; but it is frankly admitted that in spite of these forms of treatment failures are not uncommon.

THE ANNUAL MEETING IN EDINBURGH.

THE date of the Annual Meeting of the British Medical Association in Edinburgh is rapidly approaching; there are now left only six clear weeks before the assembly of the Representative Meeting, which is fixed for July 15th —St. Swithin's Day, though we may hope only for a flood of eloquence, since Edinburgh can be very charming when the sun shines. Sir Robert Philip will give his address as President on the evening of Tuesday, July 19th, and the meetings of Sections will begin on the following day. There are twenty-one Sections, ranging from Medicine to the History of Medicine and Medical Sociology, so that however large the attendance there ought to be plenty to occupy and interest every member. It is fully anticipated that the numbers present will be large, for Edinburgh is one of the famous medical schools, and will undoubtedly attract many of its graduates; in fact, the attendance is expected to be so large that some apprehension is felt with regard to the capacity of Edinburgh to put up all its guests. The Hotels and Lodgings Committee has definitely engaged all the available rooms in the city and will allocate them in rotation. The Scottish Medical Secretary, Dr. Drever, has undertaken to do this, and applications for rooms should be addressed to him at the Edinburgh House of the Association, 6, Drumsheugh Gardens. A form of application was, for the convenience of members, printed in the advertisement pages of our issue of last week (p. 28). The accommodation is grouped into three classes—hotels, where the tariff for bed and breakfast ranges between 8s. 6d. and 14s., private hotels and boarding houses (5s. 6d. to 8s. 6d.), and hotels (8s.), which, though few in number, can all be recommended. Naturally the committee is anxious to get an estimate of how many members it is to expect, and earnestly desires that applications for rooms should be made at once. The railway companies serving Edinburgh have agreed to issue passenger tickets to that city available from July 13th to 25th, at the ordinary single fare and one-third for the double journey. The printed form, which can be obtained from the Financial Secretary of the Association, Tavistock Square, W.C.1, must be filled up and signed by the applicant and given in at the booking office where the ticket is bought. The concessions as to fares will operate from Irish ports by railway-owned steamers, and by the boats of the Belfast Steamship, British and Irish Steam Packet, the City of Cork Steam Packet Companies, and the boats of Messrs. Burns and Laird. For those who propose to motor to Edinburgh garage accommodation for at least 1,125 cars will be available; application in this case also should be made to Dr. Drever. The Pathological Museum, which is now a regular feature of the Annual Meeting, has been brought together by a committee of which Professor J. Lorrain Smith is chairman; an extensive series of demonstrations will be given, of which a list will be found in the SUPPLEMENT of May 7th (p. 193). It is hoped that those who contribute to the Museum, and particularly those who wish to supplement by exhibits their contributions to the Sections, will be present at stated times to demonstrate their specimens. Communications on this matter should be addressed either to Dr. James Davidson at the Department of Pathology, The University, Edinburgh; Mr. W. Q. Wood (48, Northumberland Street, Edinburgh), or to Dr. Douglas Miller (57, Manor Place, Edinburgh), who are secretaries of the committee. The Lister centenary celebration will be held in the McEwan Hall of the University on Wednesday, July 20th, at 8 p.m. The Earl of Balfour, Chancellor of the University, will preside, and short addresses will be given by Sir William Watson Cheyne, Professor Tuffier of Paris, Professor Harvey Cushing of Harvard, and Professor John Stewart of Halifax, Nova Scotia. Throughout the week of the meeting of the Association a museum of Lister's relics, gathered from many sources, will be on view in the Upper Library of the old University. A Lister Memorial Volume has been prepared and will constitute the Book of the Edinburgh Meeting of the Association. A copy will be presented to each member of the Association on registration. The volume is edited by Dr. Logan Turner, and will contain sketches and reminiscences by former house-surgeons of Lord Lister's, two of his own scientific addresses, and a series of letters. There will also be a section dealing with the lives of Lister's fellow residents in the Edinburgh Royal Infirmary during the summer of 1854. Sir Edward Sharpey-Schafer has contributed a sketch of Lister's work as a physiologist; Mr. Miles writes on surgery before Lister, and Professor John Fraser on the influence of Lister's work on surgery. On Saturday, July 23rd, a limited party will make an excursion by special train to Fife and St. Andrews, and will be entertained at luncheon at St. Andrews by the Fife Branch; on Sunday, July 17th, there will be an excursion by road for the Representatives and their friends to the Scott country.

PINEL AND VULPIAN.

As we announced on April 9th, the celebration of the centenary of the death of Pinel, organized by the Société Médico Psychologique, is being held at Paris, from May 27th to June 2nd, simultaneously with the celebration of the birth of Vulpian under the auspices of the Société de Biologie and the Société de Neurologie. Among the psychiatrists and neurologists from many countries who will take part in the celebrations are not a few from Great Britain; the British Medical Association is represented by Dr. C. Hubert Bond, Commissioner of the Board of Control. Both Pinel and Vulpian were attached to the Salpêtrière Hospital in Paris, where celebrations will be held as well as at the Sorbonne and the Faculty of Medicine. Philippe Pinel, who was born in 1745, and died at the ripe age of 81 in 1826, is best known in this country and to the world generally for being the first to introduce humane treatment for the insane; his example was followed in England by Gardner Hill at Lincoln Asylum, and John Conolly at Hanwell. Pinel first intended to adopt a theological career, and it was not until the age of 30

that he obtained his medical qualification. His previous literary and philosophic studies, however, had not been in vain, since they enabled him to take a wider outlook than might otherwise have been the case. Shortly after obtaining his degree he translated into French William Cullen's work on nosology, which at the time had an extensive vogue. During his life, and for many years subsequently, Pinel's fame rested less on the revolution he effected in the treatment of the insane than on his being the founder of a new system of nosology in which he sought to classify diseases by their symptoms, and not by their morbid anatomy. As Pinel may be regarded as one of the pioneers of modern psychiatry, so Vulpian may be ranked with his friend and contemporary Charcot as one of the pioneers of modern neurology. Vulpian was born in Paris in 1826, and graduated in 1853 with a thesis on the origin of several cranial nerves. After acting as assistant to Flourens, who was professor of physiology at the Museum of the Jardin des Plantes, he was appointed professor of morbid anatomy at the Faculty of Medicine in 1867, and held the post until 1872, when he succeeded Brown-Séquard in the chair of comparative and experimental pathology. He was dean of the faculty of medicine from 1875 to 1881, and, during his term of office, was the active spirit in bringing about several reforms in the medical school, including the installation of new laboratories and the creation of more professorships. In addition to being a member of the Académie de Médecine and later of the Institut de France, he was made perpetual secretary of the Académie des Sciences, thus receiving one of the highest honours to which a French savant can aspire, and being the first medical occupant of this post. Like his predecessors Cruveilhier, Laennec, Louis, and Bretonneau, Vulpian combined a keen clinical instinct with a study of morbid anatomy, but he surpassed them by being the first to realize the importance of the microscope in pathology, especially in diseases of the nervous system, as is shown by his classical work on infantile paralysis, disseminated sclerosis, tabes, paralysis agitans, and changes in the muscles following section of the nerves.

COLOSTOMY.

TRADITIONAL beliefs die as lingering a death in medicine and surgery as in all else, and the operation of colostomy affords an excellent example of the way in which a method of treatment may be pursued by a bad character acquired in its early and experimental stages. To avoid the then dangers of opening the peritoneal cavity the early colostomy openings were made in the lumbar region, and the lot of the unhappy patient was indeed lamentable, for in general the opening was little more than a lateral window in the bowel, and not only was drainage inefficient, but it was also uncontrollable. Many of these unhappy patients were in consequence almost cut off from all forms of social or other activity, and when it is remembered that the operation was usually performed for the relief of the last stages of cancer of the rectum, it is not difficult to realize how colostomy came to be regarded by all concerned. Any operation carried out upon a patient who, in any event, is certain to die—no matter how successful it may be in its immediate object—is not likely greatly to enhance the reputation of the surgeon or of the art of surgery; and when that operation was characterized by the distressing concomitants inseparable from the earlier type of colostomy, it is not surprising that it acquired a very bad name indeed. Happily the rise of abdominal surgery and the introduction of sigmoid colostomy wrought a great change. The operation proved safe and easy, and the more conveniently situated wound allowed an adequate and complete emptying of the bowel. It was soon apparent that a patient with colostomy could lead a decent and fairly useful life, but it was of course still only a palliative, for the patients were all doomed as the growth extended. The next stage was the introduction of methods of complete removal of the rectum followed by permanent colostomy, and for the first time a new problem presented itself—patients cured of cancer of the rectum, but saddled with an artificial anus for life. It is in these cases, some of them strong, vigorous, and busy people, that the function and behaviour of the new opening is of supreme importance. How far colostomy has advanced and how high a degree of efficiency and control can now be promised was made very evident at the annual meeting of the Subsection of Proctology of the Royal Society of Medicine, held on May 11th, when its technique, its indications, and the after-care of colostomy cases were all exhaustively considered. Mr. Ernest Miles and Mr. Gabriel opened the discussion by describing the methods employed at the Cancer Hospital and St. Mark's Hospital respectively. It appears that in general the staff of St. Mark's use an incision through the rectus muscle and claim for it a higher degree of control than can be obtained by the incision in the iliac fossa favoured by Mr. Miles and his supporters. While it is true that in weight of numbers the St. Mark's method received more support, Mr. Miles's great experience and wise judgement cannot on that score alone be disregarded. Possibly the truth of the matter lies not so much in the site of the operation as in the mode of its performance, for all speakers were agreed that the really fundamental factor is the formation of a good spur. Given a well placed opening, a satisfactory spur, and a reasonably intelligent patient, a busy, active, and not unpleasant life is possible. The labourer can earn his living, the mother can look after her children, and the professional man can pursue his usual avocation. Indeed, dancing and dining out would appear to be not impossible. One speaker went so far as to claim that the subjects of colostomy were in some respects better off than their fellows on the ground that the daily evacuation of the bowels through the new stoma is so complete as entirely to remove any of the usual symptoms of auto-intoxication, and confers upon them notably clean tongues, sweet breath, and clear complexions. Despite all that may be said to the contrary, most people will agree that no matter how well these patients may feel, and be their breath never so sweet, yet the fact remains that no man or woman familiar with the circumstances would willingly accept colostomy did not death itself weight the balance of decision. But with death imminent or remote as an alternative it becomes a small price to pay for even temporary deliverance, a price that most of us would pay without demur. It is a comforting reflection that when we do have to advise colostomy and can combine with it an effective removal of the growth, we are offering a good chance of cure as some set-off against the disability.

THE PROBLEM OF THE DIPHTHERIA CARRIER.

THE long-continued isolation which is sometimes necessary in the case of diphtheria carriers, whether convalescent patients or contacts, is frequently a source of annoyance both to the medical practitioner and to the luckless individual whose liberty is restricted. Morphological examination of throat swabs seems to have been rather inspired hitherto by the saying of the Bellman in Lewis Carroll's *Hunting of the Snark*: "What I tell you three times is true," three successive negative results being required for liberation of the prisoner. Although there is a good deal of evidence that the virulence of diphtheria bacilli is relatively constant, and that apparent changes of virulence in consecutive subcultures are actually due to the association of a virulent with an avirulent strain, yet there

ins the possibility that the predominance of one or type at the time of testing might lead to an erroneous asion as to infectivity. Margaret Benttie and Mary have therefore made an examination of the criteria resent employed in determining the release of such ers. The questions they considered were: (1) Is a negative virulence test sufficient to allow of the e of a carrier? (2) Is a person who has once been to be carrying virulent diphtheria bacilli to be dered dangerous so long as diphtheria bacilli are nt? To answer these questions they performed ted tests on bacillary strains recovered from a number ntacts and carriers. Whole cultures were injected cutaneously in 0.2 c.cm. quantities into guinea-pigs, of which were protected by a simultaneous dose of oxin. Of 47 carriers tested, 11 gave persistently tive results of virulence tests. Of the others, 32 gave ive results the first time, and 4 gave negative results irst time but positive results on one or more subse- t occasions. Of the 32 patients that gave a positive ence test on the first occasion, 7 subsequently became tive—that is to say, 21.9 per cent. of patients giving nitial positive virulence test subsequently became tive, whereas of those giving an initial negative test per cent. subsequently became positive. Since in half the patients only two tests were made, it is clear these figures cannot be considered as representing true proportion of alterations in virulence; had a r number of tests been made it is probable that they d have been different. (The figures given are those ie tables; the figures in the text do not agree with absolutely.) The conclusion to be drawn from these ts would seem to be that from an administrative point iew repeated virulence tests are of value, not only in ling certain carriers to be released before morpho- al diphtheria bacilli have disappeared from the throat, also in preventing the premature discharge of carriers on a single test, might be considered innocuous.

ENZOIC ACID IN THE PRESERVATION OF FOODS.

ER the provisions of the Public Health (Preservatives, in Food) Regulations which came into force on uary 1st last, the only preservatives permitted to be in foods and drinks are sulphurous acid and benzoic . The articles to which the preservatives may be ed, and the maximum quantity allowable, are specified schedule. Unfortunately little work has been done his country on the estimation of benzoic acid, so that Ministry of Health has thought it advisable to publish view of available information on the subject in the of a report on *The Determination of Benzoic Acid Foodstuffs*,[2] by Dr. G. W. Monier-Williams. The culty of the subject is illustrated by the story of a lor of pickles in America who was prosecuted on the und that his product contained benzoic acid. As a ter of fact his pickles were highly flavoured with oil cinnamon, which gives similar reactions. Moreover, zoic acid occurs naturally in certain berries, such cranberries, whortleberries, and especially cowberries, ch are *common articles* of food. Dr. Monier-Williams s that for the determination of benzoic acid in food- fs removal or destruction of proteins is almost always essary, as they are liable to cause emulsions on ex- tion with solvents, and also to retain benzoic acid. the same time the removal of proteins by precipitation lead to loss of benzoic acid in various ways. With ls containing much fat it is better to separate the fat to extract the benzoic acid independently from the fat and from the fat-free residue. Steam distillation is a satisfactory method of extracting the acid from non-fatty foods. In nearly all cases purification of the extract is required before titration or weighing can be done. Washing with salt solution is a good way of purifying; and oxidation with alkaline permanganate is effective in removing many impurities. Precipitation of insoluble benzoates is only of limited application; while sublimation, the best and most reliable method of purification, may fail if much impurity is present. The most delicate test for benzoic acid is Mohler's. Dr. Monier-Williams concludes his report by describing a new method of distillation for the determination of benzoic acid in fruit and vegetable products.

THE STUDENT WHO SMOKES.

ACCORDING to a venerable anecdote, two men followed one another into a public house one spring day and each ordered a brandy and soda, the first because the cold wind tried him, the second because the hot sun made him feel faint. A third man, who had heard both orders given, said to the barmaid: "Bring me a large brandy and soda, miss, because I like it." It is probable that a majority of adult smokers would, if quite honest with themselves, assign the third man's reason for their habit, and it is really a very good reason. Still, as Professor Boycott says in his preface to Dr. Earp's study of *The Student Who Smokes*,[1] "we have been smoking in this country for about 350 years, and it is no doubt time that we knew more about the effects than we do." Dr. Earp, who is the director of the Department of Hygiene in Antioch College, Yellow Springs, Ohio, set himself to investigate some of the effects of smoking upon a sample of young men. He has analysed statistically the physical and mental prowess of college undergraduates who were or were not smokers. The data relating to athletics are not, from the nature of the case, very extensive, but, so far as they go, confirm the general impression that habitual smoking is not favourable to the development of athletic prowess. The data relating to intellectual activity are novel and interesting. In the first place, the results of psychological tests at or before admission show no significant difference between smokers and non-smokers to the prejudice of the former; in fact, in one series of tests the smokers had a statistically significant advantage. But if one takes the frequency distributions of marks gained in college, the smokers had a lower average and were more variable. Taking a grade of 4.0 as a mark of reasonably high scholarship, it appears that 23.9 per cent. of the non-smokers and only 7.9 per cent. of the smokers reached or exceeded this mark. On the other hand 37.9 per cent. of smokers failed to reach an average grade and only 18.8 per cent. of non-smokers. It also appears that the heavy smokers did not do so well as the light smokers. Thus 41.4 per cent. of 353 students failed to reach diploma standard, 62.7 per cent. of 75 heavy smokers, 42.1 per cent. of 95 lighter smokers, 31.8 per cent. of 176 non-smokers. There is also some evidence that the smokers deteriorated slightly from year to year, and some evidence that inhalers did worse than non-inhalers (we think that in the latter case, the method of treating the statistics has somewhat over-estimated the significance of the difference, but the point is technical). On the whole, then, the smokers come out of the trial rather badly, and Dr. Earp asks himself why. He considers three hypotheses. The first that smoking is, to some extent, a measure of sociability, and that sociable lads have less time to ponder in solitude over the properties of right-angled triangles and the uses

[1] *The Student Who Smokes: An Original Statistical Investigation.* By J. Rosslyn Earp, M.A., M.R.C.S., L.R.C.P., Dr.P.H. With a preface by A. E. Boycott, M.A., D.M., F.R.S. London: H. K. Lewis and Co., Ltd. 1927. (Med. 8vo, pp. 62. 5s. net.)

of the subjunctive mood. The second theory is that those who smoke are happy and content and do not feel the cravings of an ambition to know all about triangles; as Emerson puts it, "The believing we do something when we do nothing is the first illusion of tobacco." The third theory is that some poison or poisons in the smoke act directly upon the central nervous system. Dr. Earp slightly inclines to favour the third theory—he attaches more importance than we are inclined to do to his comparison of inhalers with non-inhalers—but his summing up is judicial, and he concludes that "more than one, perhaps more than all, of the explanations ventured above are necessary to cover all the facts." This is an interesting piece of work which should be repeated elsewhere for a reason mentioned by Dr. Earp in another connexion. As he says, "in some environments the non-smoker is made to feel socially an outsider; and in others the smoker is consciously wicked." If we wish to determine the intrinsic virtues or vices of tobacco we ought to take a sample of persons from a "universe" where smoking is regarded from the moral and social point of view with complete indifference, and so we should avoid the risk of some other factor correlated with the use of or abstention from tobacco complicating the matter. There is not, indeed, any evidence that the "universe" sampled by Dr. Earp is other than indifferent; the facts (1) that in his sample there were as many smokers as non-smokers, (2) that the sets of questions issued failed in a large proportion of cases to elicit strong reasons for or against smoking, rather suggest that the population from which the students are drawn has no very strong pro- or anti-*nicotine opinions. Still, the point is so important that* it ought to be tested in many ways, and we share Professor Boycott's hope that Dr. Earp's work will stimulate others.

ANTHROPOLOGY AND MAGIC.

MANY members of the Royal Anthropological Institute visited the Wellcome Historical Medical Museum on May 24th to hear an address on the anthropological sections of the museum by Professor Elliot Smith, F.R.S. Very many of the objects, he said, represented the strivings of men to protect themselves, out of which strivings had developed the great majority of the customs and beliefs of mankind in all ages and countries. Here were gathered, for instance, a large number of amulets, talismans, elixirs, and devices, which had in common the idea of protecting or prolonging man's existence. Many of these things appeared grotesque, even quite ridiculous, as means of bringing good luck to their owner, or, in other words, protecting from danger. But *properly to understand* magic it is necessary to remember that most of the things now called magical were originally objects devised on purely rational grounds as mechanisms of protection. It was only when such measures were shown to be unjustified, but were persisted in by a number of people owing to habit or fear, that they could properly be described as magical. Thus certain folk believed in the efficacy of shells, beads, bits of bone, and similar objects long after any justification for the ideas of virtue relating to them had disappeared. Some remarkable representations of pharmacies had been gathered together in the museum, ranging from an early English alchemical manufacturing laboratory down to the shop of the modern druggist, and here was an amazing demonstration of continuity from the early equipment with which Paracelsus might have worked down to a rational pharmacology. Altogether the museum helped the student of anthropology to interpret the real meaning of the customs and beliefs of primitive people, and in bringing together this collection Mr. Henry S. Wellcome had rendered a distinct service, not only to medicine and pharmacology, but to anthropology. A vote of thanks to Mr. Wellcome was accorded on the motion of the Earl of Onslow, seconded by Mr. W. G. Spencer, and a message from Mr. Wellcome was read by the conservator, Mr. L. W. G. Malcolm, stating his desire that the anthropological section should be developed as a *progressive research institution.* The members then inspected the collections, especially those dealing with divination, magic, and witchcraft.

YATREN.

IN 1921 Professor Mühlens and Dr. Menk of the Hamburg Tropical Institute reported some excellent results from the use of a new remedy for amoebic dysentery. This was a preparation manufactured by the Behringwerke at Marburg; its chemical composition was given as iodo-oxyquinoline sulphonic acid; it was stated to contain 28 per cent. of iodine, and was put upon the market under the name "Yatren 105." It is a yellowish powder, soluble in water to the extent of 4 per cent. at the ordinary temperature, and has the advantages of acting efficiently when taken in pill or cachet by mouth, of being innocuous and non-toxic, and in maintaining its potency on storage. During the last six years good reports have been published from countries other than that of its discovery, Germany —namely, by Silva Mello in Brazil, Birt and Reiss of Shanghai, de Langen and Lichtenstein in Batavia, Manson-Bahr in England, Buchanan in Palestine, and others. Dr. Schwartz of the Faculté de Médecine de Paris has conveniently brought together in a pamphlet[1] these scattered records, and has added four cases of his own. He shows that though *from its solubility* "Yatren 105" can be employed as a rectal injection, it acts equally well when taken in pill or cachet (four pills each containing 0.25 gram, or two cachets each of 0.5 gram, daily being the *doses generally recommended*), and is thus much more convenient than emetine; and, further, it is of service also as a prophylactic, needs no special precautionary measures, and can be carried on a journey and taken in the course of travel. The drug appears to be very efficacious *in acute* amoebic dysentery, and to have given good results in chronic cases, but it is only right, before we accept the report of cure, to suspend judgement in the latter until a longer interval has elapsed. The usefulness of such a piece of work as Dr. Schwartz has done is twofold: it brings together the experiences of workers in various countries as to the efficacy of a new form of treatment of a condition which has become widespread since the war, and which is the cause of much sickness and even mortality; and secondly, it should lead to a more extensive trying-*out of a remedy which will receive a universal welcome* if the laudatory reports hitherto published are confirmed by others.

THE centenary of the discovery of Bright's disease by Richard Bright, physician to the hospital from 1820 to 1843, will be celebrated at Guy's Hospital on Friday, July 8th. The Earl of Balfour, K.G., F.R.S., will attend, and at 3 p.m. Dr. W. S. Thayer, Emeritus Professor of Medicine, Johns Hopkins University, Baltimore, will deliver the Bright Memorial Oration in the Physiology Theatre of the Medical School. Academic dress will be worn.

THE Oxford University Junior Scientific Club announces that the twenty-ninth Robert Boyle Lecture will be delivered on Saturday, June 4th, at 9 p.m., in the hall of Balliol College by Sir Leonard Rogers, M.D., F.R.S., upon "Climate and disease incidence in India; forecasting epidemics."

THE FUTURE OF THE UNIVERSITY OF LONDON.

THE NEW SITE IN BLOOMSBURY.

THE purchase by the Senate of the University of London of what has been known for some years as the University site in Bloomsbury, immediately to the north of the British Museum, is undoubtedly one of the greatest advances towards the solution of the university question in London which have been made since the University was founded in 1826. As we announced in our issue of May 14th (p. 906) the Senate of the University has been enabled to acquire this site owing to two grants recently made to it. In July last, only a few months after the Duke of Bedford had resumed possession of the site which had been offered to the University in 1921 by the Government, under conditions with which it was then unable to comply, the Chancellor of the Exchequer promised to make the University a grant of £212,500 for the purpose of enabling it to provide new accommodation at South Kensington on the ground immediately behind that portion of the Imperial Institute which it now occupies, and for the purchase of such an amount of land on the Bloomsbury site as might be possible and within the financial resources of the University. The whole situation was changed by the recent offer of the Rockefeller Trustees to assist the University in the purchase of the entire site originally offered to it in 1921. We believe we are right in saying that the suggestion in this direction was only made by the Rockefeller Trustees in January last. We congratulate those who are responsible for the administration of the University on having achieved a large part of its object within three months of announcing negotiations for a purchase of part of this important site.

As we have already stated, the area now acquired is oblong in shape, and extends from the northern frontage of the British Museum to Gordon Square. It is bounded on the west by Malet Street, and on the east by Russell Square and the road leading from that to Gordon Square. This site comprises without the roads 8½ acres, and with the roads 11½ acres.

The Rockefeller Foundation was founded with the object of promoting in its widest sense "the well-being of mankind throughout the world." As is well known, in carrying out the primary object of the Foundation the Trustees have made considerable gifts for the establishment of institutions in connexion with medical education in different parts of the world. One important foundation of this kind already exists in London. Immediately adjacent to the new University site, between Malet Street and Gower Street, is the London School of Hygiene and Tropical Medicine. Its foundation charter was granted in April, 1924. The founding of this institution followed an offer by the Rockefeller Trustees of two million dollars towards the cost of building, and a guarantee by the Government of the sum of £25,000 a year for its administration and up-keep. Later on the Rockefeller Trustees promised to give £4,000 a year to provide for the payment of a director and an administrative staff. Dr. Andrew Balfour was accordingly appointed director, and he and his staff have been at work making preliminary arrangements ever since. The School was established by Royal Charter, and is governed by a Court of Governors, and a Board of Management nine in number. Since its foundation the School has taken over the administration and responsibilities of the London School of Tropical Medicine, which was established through the exertions of Sir Patrick Manson in connexion with the Seamen's Hospital at Greenwich at the Albert Dock branch. He lived to see it removed to the large building in Endsleigh Gardens, which included a teaching school, laboratories, and hospital wards. The School of Hygiene and Tropical Medicine will become, as provided in its charter, a school of the University of London as soon as its buildings have been erected and equipped.

Immediately after its appointment the Board of Management of the School of Hygiene and Tropical Medicine instituted an architectural competition for plans for the erection of the buildings required by the School on the site which had already been bought at a cost of £50,000 from the trustees of the Duke of Bedford. This architectural competition was limited to a select list of architects all of whom had had previous experience in connexion with the building of scientific laboratories, either for universities or large medical schools. As we have previously stated, Mr. Morley Horder was successful in this competition. After careful discussion by the Board of Management of the successful plans, and with a number of modifications in detail, it was determined to proceed with the construction of the building. The foundation stone was laid by the Minister of Health (Mr. Neville Chamberlain) on July 7th, 1926, and if the coal dispute had not occurred with its consequent difficulties in the provision of constructional steel, the building would by this time have been well advanced. At the present moment, however, great progress is being made. The steelwork is well under way, and the main contract has been let, and within a short time—two years or less—there will have been erected and ready for occupation what we trust will be one of the finest scientific buildings in London, and is without doubt destined to become one of the greatest schools of hygiene in the world.

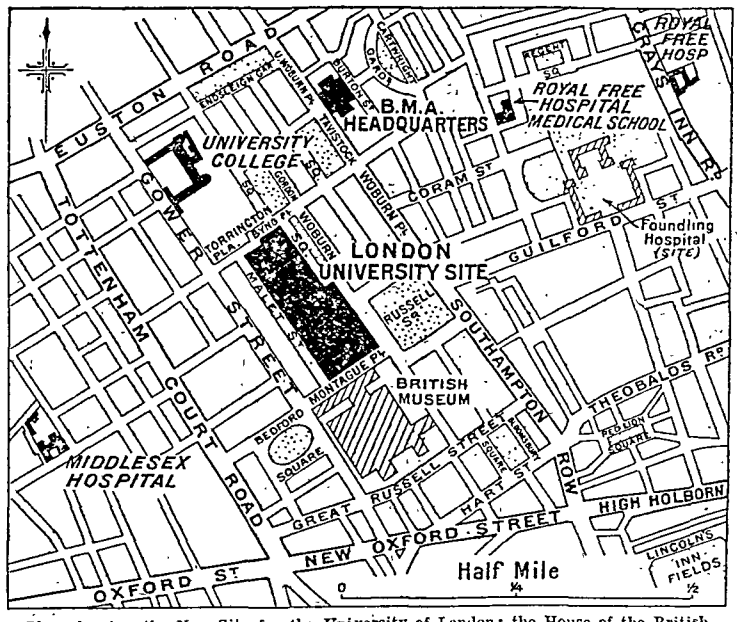
So much for what has already been arranged and is in course of construction on the area immediately adjacent to the University site.

We trust that the Senate before allocating for the purpose of any individual building any portion of the site which has been acquired will, in the first place, decide on broad lines what the institutions to be erected in Bloomsbury are to be. An open architectural competition, in which information is given as to the institutions proposed for the site, will in all probability result in a satisfactory plan. A liberal spirit ought to be observed in these suggested plans; and, if possible, the assistance and collaboration of the London County Council and the local municipal authorities obtained.

It must be remembered, however, that the University will only be able to proceed gradually with the erection and equipment of its buildings. In the first place it, at the present time, has only available a sufficient sum of money for the erection of a central administration office. The decision of the Senate, which was made on February 23rd, 1927, to remove, if possible, the administrative offices from the site at South Kensington to Bloomsbury, was a most important one. The transference of these offices to Bloomsbury will be an enormous advantage in the future to everyone connected directly or indirectly with the University. The teaching staffs of

the various constituent colleges and the students will find that with very few exceptions it is a far easier matter to get to the University at Bloomsbury than to South Kensington, owing to the means of transport to and from the Bloomsbury area. Only those who have been intimately connected with the University, and have had frequently to go to South Kensington, can realize the difference in the administration and in all university activities which this transference to Bloomsbury will make.

The institutions which it has already been suggested might be located and erected on the Bloomsbury site are:



(1) *The Central Administrative Offices.* Concerning the necessity of these there can be no doubt.

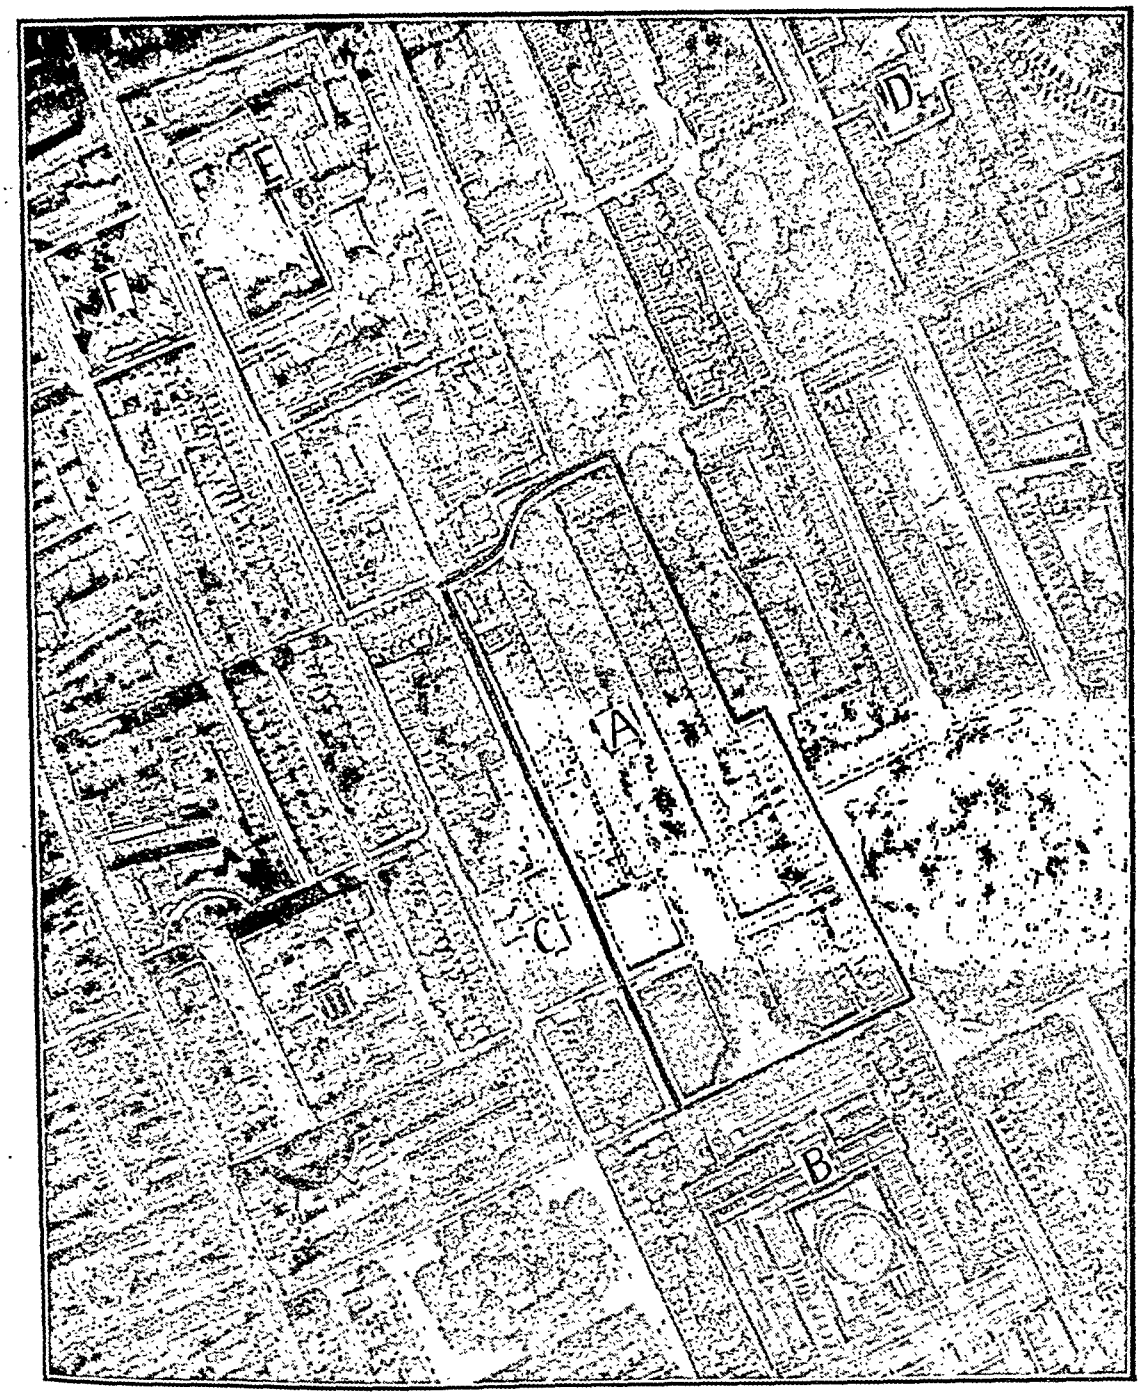
(2) *The University Library.*

(3) *The School of Historical Research*, at present inadequately accommodated in a series of temporary one-storied buildings on a portion of the site in Malet Street.

(4) *A Students' Union*, or perhaps better still a University Union, which might become a centre for the social activities of teachers and students of the University, and a centre where hospitality might be dispensed to students from overseas and from other universities.

(5) *A Senate House or Ceremonial Hall.*—Some would prefer the latter, but it is to be hoped that the University will not attempt to provide an enormous hall for its public functions. One of reasonable size would, in the long run, be found much more useful and certainly much more economical. It might be asked in this connexion what is to happen with regard to the graduation ceremony. For some years this has been held in the Albert Hall to provide room enough for the large number of graduates upon whom degrees have to be conferred. It has been the custom of the University of London to confer all the degrees and present all diplomas obtained during the preceding year on the second Wednesday in May. The University, instead of this, might follow the practice of most other universities, and publicly grant its degrees on several occasions during the year and immediately after they have been gained. This year, according to the report of the principal officer, the number who obtained degrees and diplomas in the academic year 1926 was 3,173. In the circumstances, which we may now confidently hope will be brought about within a few years, it will no longer be necessary to continue to hold an annual graduation ceremony in the Albert Hall. The Senate has partly clung to the policy of holding this one immense function in order to attempt to bring the existence of a university in London before the community. When a suitable building has been erected on the Bloomsbury site in the centre of London it will soon become known to the world at large as *the* University of London; this is a matter of considerable importance, which ought to receive attention so soon as the general lay-out plans of the new buildings come under consideration. At the present time the building in which the headquarters of the University of London are established is so little known to the community at large that when a taxi driver is directed to drive there he either asks for instructions, or goes to Gower Street or anywhere except South Kensington.

Plan showing the New Site for the University of London; the House of the British Medical Association; and the main buildings of University College.



(6) *Site for Certain Constituent Colleges.*—It has been suggested that certain colleges, such as Birkbeck College, might be allocated sites in the University area, and also that provision should be made for residential hostels, or quarters, for some teachers and students.

(7) *The Headquarters of the Officers' Training Corps.*—Provision for proper headquarters of this important part of the University work is very essential. In the past, as we all know, the University of London Officers' Training Corps has done excellent work, and is doing so at the present time. It is doing it, however, under very great difficulties and in very bad accommodation.

(8) *Administrative Offices for a Post-Graduate Medical School.*—From the point of view of medicine one of the most urgent needs of London is a post-graduate medical school. It may be suggested that space for a suitable building, to serve as the administrative headquarters of such a school, might be found on the Bloomsbury site. Many attempts have been made to provide in London a satisfactory and efficient post-graduate school; all up to the present have failed. Each school of this kind which has been attempted has never had a permanent headquarters or an efficient administrative staff. Further, no post-graduate school or association in London has ever been intimately or directly connected with the University or any of the medical licensing bodies. If a post-graduate school in London is to be a permanent success in the future we unhesitatingly say that it ought to be a school of the University, as the Athlone Committee indeed recommended; and it might be well that it should also have direct connexions or associations with the governing bodies of the Royal Colleges of Physicians and Surgeons.

Now that the University has acquired a central site upon which are a number of buildings, it might perhaps consider the possibility of allocating accommodation for the headquarters of a post-graduate school and take part in its formation on sound lines and in its administration. One great difficulty that has in the past stood in the way of the creation of a satisfactory post-graduate school of medicine has been the aversion of all the medical schools in London to give up their undergraduate work to become a post-graduate school. It is well known to everyone who has had extended experience of medical education that it is impossible to carry on in the same hospital and the same medical school an efficient and satisfactory post-graduate school and an undergraduate school. For some reason undergraduate students and post-graduates refuse to mix for educational purposes.

(9) *A University School of Law.*—The creation of a school of law in the University of London has in the past often been suggested and discussed. Provision for teaching in law has been made in the larger colleges of the University, for instance, in University College and King's College, and at the School of Economics, but any intimate connexion between those great law corporations—the Inns of Court and the Law Society—and the University has hitherto been found impossible. On several occasions discussions have taken place with the authorities of these institutions

(From an air photograph by Aerofilms, Limited.)

with the object of creating a school of law, which might be known as such. When the University was reconstructed in 1898 the commissioners put upon the new Senate representatives of the law corporations. These were six in number, a representative each for Lincoln's Inn, the Inner Temple, the Middle Temple, and Gray's Inn, and two representatives of the Law Society. This was a larger representation of institutions than in any other branch of education on the Senate. Closer working between these law corporations and the University did not result. Presumably on account of this failure in twenty-five years to effect any closer connexion between the University and the law corporations, and the desire to diminish the size of the Senate, the six representatives under the new constitution automatically disappear. In the recent reconstitution of the Senate a similar result happened with regard to the Royal Colleges of Physicians and Surgeons. They had been represented on the Senate by four members, two appointed by the Royal College of Physicians and two by the Royal College of Surgeons. As with the law representatives these four representatives were appointed when the University was reconstructed in 1898, the intention being to bring about a closer working between the Royal Colleges and the University as regards its medical faculty. We cannot help regretting that the University and the Royal Colleges have not found it possible in the past twenty-five years, during which period the Colleges have had representatives on the Senate, to evolve some such system of closer working. It would be an enormous advantage to the students of the medical schools in London if the University and the Royal Colleges could establish examinations which in part were common to the three bodies. Many members of the London medical schools who have been examiners to the University and to the Royal Colleges in medical subjects, especially as regards the final qualifying examinations, say that in reality there is little difference between the final examinations of the three bodies. The University has additional examinations in some special subjects, whereas the Colleges combine these subjects. Surely it would be possible to evolve some plan by which the University and the Colleges could carry on joint examinations. This is a subject which deserves serious consideration in the immediate future. There is no doubt it is becoming increasingly difficult to find men of recognized position and superior attainments who are willing to give the time which is necessary to the examinations of the three bodies.

(10) *Central Hospital for Tropical Diseases.*—There is, we believe, a proposal to establish a central hospital for tropical diseases in the immediate neighbourhood of the School of Hygiene and Tropical Medicine. If this is done, and we do not doubt the necessity, we hope that it will be in its immediate neighbourhood, such as the area now vacant immediately to the south of the frontage of the new buildings now being erected in Keppel Street. The site is opposite the London School of Hygiene and Tropical Medicine, and its buildings might be made architecturally and otherwise to correspond.

(11) *A Residential Campus.*—At the graduation dinner held at the Fishmongers' Hall on the evening of the graduation ceremony on May 11th it was interesting to hear an allusion in one of the speeches to the possibility of the creation of a central university residential campus in Bloomsbury. We are told that the roll of internal students in 1926 comprised 9,340, and that there were 850 foreign and oversea students attending university institutions in London. Only a small proportion of these internal students would require residential accommodation, but for the oversea and foreign students it seems essential that residential accommodation should be provided.

It was suggested that in the immediate neighbourhood of the University there was a site which might be acquired for such a university residential campus. The site mentioned was that of the Foundling Hospital. Perhaps some of our multi-millionaires who are desirous of doing the best they can for the country and the empire might give serious consideration to the suggestion. It would be difficult to imagine anything which would promote the interests of the country and the empire more than the establishment of residential accommodation of a proper kind, and in such a position as is suggested.

There are many other points in connexion with the development of the University site in Bloomsbury which we should like to have discussed, and perhaps in a future issue we may be able to pursue the possibilities of development of the Bloomsbury site in connexion with the University and university education.

THE ODONTOLOGICAL COLLECTION OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.

THE Odontological Collection of the Royal College of Surgeons of England has been completely reconstructed and rearranged under the direction of Sir Frank Colyer, K.B.E., F.R.C.S., who has been curator for over twenty-five years. It was formally opened by the President, Sir Berkeley Moynihan, Bt., on May 23rd, when the Section of Odontology of the Royal Society of Medicine held its annual meeting by invitation in the College. Sir Berkeley Moynihan spoke as follows:

Address by Sir Berkeley Moynihan.

There is little need for me to attempt to lift up your blood with persuasion in order to convince you of the importance of the odontological collection which now finds a proud and permanent place in our Hunterian Museum. It affords beyond question the most complete representation ever made of all that concerns the teeth—of their origin and growth, of their structure, their disorders, their comparative anatomy and comparative pathology. It is a collection which we who are responsible for the welfare of this Museum feel ourselves most fortunate to possess.

May I briefly remind you of the steps which have led to the formation of our collection and seek to interest you in its further progress; for happily there is no finality in any department of surgery—least of all perhaps in that which relates to the dental system?

Seventy years ago the leading dental surgeons of this country formed the Odontological Society of Great Britain. With great foresight they began at once to preserve and collect the more instructive specimens shown at its meetings, and thus in course of time they found themselves in possession of a large museum. In 1907, when the Odontological Society became the Odontological Section of the Royal Society of Medicine, this museum had so grown that it contained no fewer than 5,000 catalogued specimens. It was then in charge of an indefatigable and devoted honorary curator, Mr. J. F. Colyer, and Sir Frank Colyer, I am glad to say, is still honorary curator of the collection, and to this day displays all the energy and enthusiasm, and even more than the high competence, of twenty years ago.

Those responsible for the management of the newly formed Odontological Society naturally regarded the Museum as an essential part of their organization. They recognized also that if the collection were to continue to expand it would be better to place it where the necessary skill in the preparation and preservation of additional specimens would still be available, and where it would meet not only the immediate needs of the society, but would also serve the manifold purposes of a great national collection. With these objects in view the Royal Society of Medicine, in 1908, offered the collection, as a trust, to the Council of the Royal College of Surgeons; the trust was accepted by the council, and by the end of 1909 the collection was installed in a large new room—the "odontological room"—on the ground floor of our Museum, the cost of installation being defrayed by the College.

To the specimens assembled by the Odontological Society were added John Hunter's original specimens—things of utmost beauty of workmanship, and beyond all price both from their scientific and their historical interest. Among these are the very preparations, 83 in number, on which Hunter founded his opinion as to the manner in which teeth are formed and grow—they are known to all students from the fine drawings which were reproduced by Hunter in his *Natural History of*

...from the odontological collection of ...many of them original Hunterian specimens—to illustrate the comparative anatomy of the teeth.

The Council of the College, while gladly undertaking the responsibility of maintaining the collection, wisely acceded to the desires expressed by those who negotiated the transference, that the Odontological Section of the Royal Society of Medicine should continue to take a direct interest in the welfare and growth of the collection, should use its contents at their meetings and demonstrations, and should advise in its general management. This part of the trust, I am glad to say, has always been, and is now being, faithfully observed. The Section nominated Sir Frank Colyer as honorary curator, and through his labours, and with the generous help and unflagging zeal of other members of the Section, the odontological collection has grown with amazing rapidity. Especially has that part increased which illustrates the comparative pathology of the eth—the diseases which affect the teeth and jaws of horses, gs, and all domesticated and confined animals. This is an portant branch of knowledge which Sir Frank Colyer has de his own, and he has utilized to the full the wealth of erial placed at his disposal by the Council of the Zoological iety of London. Nor have other sources of information neglected. The diseases which occur in men living in us stages of civilization and at various periods of history here illustrated, as well as those dental diseases and lers which are found in animals living in a state of .

years ago, so greatly had the collection outgrown its accommodation, my Council had to consider how d space could be obtained. I hope you will agree with our architect, Mr. Frere, has overcome certain initial es. He has succeeded in extending the original room it is now one of most spacious dimension—large so we hope, to provide accommodation to meet not needs of the present time, but those also of the future. The collection has been rearranged, new e been added, and a new descriptive catalogue is nced in preparation. In a sense, therefore, I am laring open a new Museum—one which assuredly has any land. There is here a collection that has much the dental student anxiously concerned perhaps with s, but there is still more to offer to the student —to the dentist who is seeking to extend the on which the daily practice of his profession is is, above all, a research collection. Inquirers in ave found in its cases and upon its shelves the rials of which they were in search, and future our home schools, as well as from those overseas, an even larger scale that we have catered for s. We aim, here as elsewhere in our Museum, the maintenance but also at the progress of ll departments of surgery, and not least in that which is the province of dental surgeons.

much to say that some of Hunter's most coveries were the direct outcome of his study as the absorption of alveolar bone following a tooth that led to his views on the methods or useless parts of the body are gradually of his conclusions regarding the nature of e drawn from his observations on tooth

necessary for me to extol Hunter's funda- as to dental surgery because this aspect of so amply and so artistically dealt with in monograph, *John Hunter and Odontology*. turn over the pages of that fine work to the debt we owe to John Hunter. And ee in the collection under Sir Frank's sly beautiful preparations made by the lunter himself. The study of the teeth relation to general disorders, a study contemporary William Hunter, will pro- indeed in my judgement has already permanent influence upon general medi- ravages of oral sepsis may prove serious e complications, seemingly so unrelated a grave menace both to health and life.

I cannot better illustrate one kind of service performed by this Museum than by reminding you of a late addition. We all lament the death of the late Mr. Howard Mummery, a Fellow of this College; he had one of the most original and inquiring minds ever applied to odontological problems, and his industry and insatiable appetite for new knowledge continued throughout a long life. After his death, his microscopes, his instruments, and the material results of all his investigations were left to this collection, so that future students might benefit from his endless and unfinished labours. Without such a provision as is afforded by our museums, the lifework of a great man might be lost. As it is, the fruits of Mummery's life will be preserved side by side with the "Tomes" Collections.

The Council of this College regard as their highest trust the conservation and enlargement of this Museum, originally a legacy of Hunter's own brain and hand, and therefore held by us all as sacred. Men of high intellectual attainments, of unwearying industry, and of exquisite skill have rejoiced to labour in the Museum, and have willingly spent their best years in its service. John Hunter's influence is beyond the reach of death. His written word, clumsy and uncouth though it may sometimes be, contains a message which stirs the hearts of men in earnest pursuit of truth. Above every one in our profession of surgery he teaches by his own example the true method of approach to learning by way of observation and experiment; and his industry was simply relentless. The multitude of his specimens in our Museum shows the greedy fervour of his life-long search for stones wherewith to build the bridge from ignorance to knowledge. Close contact with him changes everything; in close contemplation of his labours and in communion with his so ardent mind men are moved to great devotion in the cause he so nobly served. Owen, Paget, Flower, Shattock—great men and great teachers—all of them were inspired by him as by no one else, and their work in our Museum is their homage to the soul of John Hunter.

To-day, on behalf of the College, I tender our sincere and grateful appreciation to two others who by long and most skilful service have greatly enriched the treasures of our Museum—Sir Arthur Keith and Sir Frank Colyer.

MEDICAL EDUCATION AND PRACTICE IN AMERICA.

THE rapid expansion of population in the United States during the latter half of the nineteenth century led to a demand for medical practitioners which was far in excess of any supply available in North America from existing centres of training. To meet the shortage many proprietary medical schools sprang into existence, turning out graduates in large numbers who, owing to the limitations of their qualifying courses, had had small opportunity for the acquisition of either knowledge or skill. American towns at one time and another produced over four hundred schools of this illusory type. Thanks to various wholesome influences, emanating mainly from the profession itself, few, if any, of them now remain. At a recent count the total number of medical schools in the United States was 79, which is still perhaps rather above the actual requirements of the country.

In the process of elimination the test of survival was that of efficiency secured under regulations. These regulations, initially strict so as to serve their immediate object, are now believed to be acting in restraint of sound medical teaching, through failure to envisage the needs of the community to which the medical graduate may be called on to minister. This consideration has engaged the attention of the Association of American Medical Colleges, one of the bodies which have been most active in the cause of reform. After sundry inquiries and discussions a Commission, including well known names, was appointed to carry out a study of the community health needs of the United States, in the hope of establishing fundamental relationships which might become a basis for the formulation

of a more elastic medical code. The Commission began its work in 1925, and has now issued a preliminary report.

The data of the report were mainly derived from the answers to a set of questions addressed to over 500 physicians, of the classes of 1915 to 1922 inclusive, engaged in general practice in communities of 50,000 or less, in 24 States of the Union and two Canadian provinces. An analysis of over 20,000 attendances shows that office consultations were 55 per cent. of the total, home visits 35 per cent., and hospital attendances 10 per cent. Allowance being made for the hospital attendances, these proportions come very near to insurance experience in the United Kingdom. In serious illness treatment was often greatly hampered by the economic status of the patient, which is seldom the case here.

The population per doctor in the United States, excluding New England, is in general less than in this country. It ranges from 536 in places of over 100,000 people to 1,338 in places under 1,000. Medical practice in isolated agricultural communities is little sought after for two reasons. The first is that standards of living there are repugnant to men of education and culture. They present, indeed, a serious national problem. The second reason, as given by the Commission, is that in many cases the young American graduate, on completion of his training, does not feel competent to assume the responsibility of an independent charge. He has been taught so to lean on laboratories and other organized services that he is reluctant to stand alone. Such young graduates, it is said, are the products of schools which have not fully envisaged the medical needs of the day.

The Commission reports that in the United States there are 15,417 specialists, or 10 per cent. of the whole profession. Among recent graduates the tendency is towards a higher rate of specialism still. For Louisiana the recent figure is 19 per cent., for Wisconsin 15 per cent., and for Connecticut 18 per cent. Of the graduates of two recent years in 52 medical schools 28 per cent. and 24 per cent. respectively were restricting their practice. The Commission expresses no opinion on these figures except to say that "the proportion of graduates practising only a specialty varies greatly with the school from which the student graduated, bearing out a general impression that emphasis in training may be a factor."

The influence of medical licensing upon medical education is regarded by the Commission as on the whole beneficial, but inasmuch as each State has its own requirements there has been considerable confusion. It was found impossible to secure the passage of identical legislation by all States, but the attempt to do so has effected much in the interests of uniformity. The freedom of the medical profession to practice has, however, been bought at a price, for most regulations extend their protection to irregular practitioners also. There is, however, a growing opinion that all healers, whether regular or irregular, should conform to the same standards of preliminary education and competence in diagnosis.

Points of resemblance between medical conditions in England, and in America as noted by the Commission, have been referred to above. Among the main contrasts emerging are the existence in America, as opposed to England, of wholly ineligible areas of practice, and the occurrence of diffidence in young medical graduates. The increasing proportion of specialists in America is impressive. It may, however, as stated by the Commission, merely reflect the attitude of certain schools. The equality before the law of regular and irregular healers is perhaps the most conspicuous divergence between the two countries. Nothing but the growth of public opinion, guided by the high example of American medicine at its best, seems likely to extinguish this offence to reason.

Of the reforms in medical teaching which may be expected to result from the data submitted by the Commission it would be precipitate here to speak. The Commission itself is apparently precluded by the terms of its reference from making concrete suggestions. The facts, however, have been declared. Medical colleagues on this side will watch with friendly interest the progress of events.

England and Wales.

INVALID CHILDREN'S AID ASSOCIATION.

LORD BURNHAM, who presided at the annual meeting of the Invalid Children's Aid Association, on May 17th, drew attention to the cordial relations which existed between the Association and the hospitals, the London County Council, the Metropolitan Asylums Board, boards of guardians, dispensaries, and nursing associations. In this way the provision of adequate treatment and after-care for the sick and crippled children of London was greatly facilitated. During 1926 help had been given in 18,000 cases, and residential accommodation in London or the country had been secured for between 7,000 and 8,000 children. A large number of invalid carriages, surgical instruments, boots, and crutches had been supplied. The income during the year had amounted to over £24,000, of which £15,230 had been received from parents towards the cost of helping their children. Sir Thomas Barlow described the origin of the society nearly forty years ago in a small band of voluntary helpers who visited child out-patients in their own homes. Convalescent homes and open-air schools were then established, an invalid school was started, and, latterly, the difficult problem of acute rheumatism was being faced. Great benefits had been obtained from the treatment by open-air methods of children recovering from acute rheumatism. An appeal is being made for £15,000 for the completion of the new institution for children at West Wickham, Kent.

THE LONDON EDUCATION COMMITTEE.

The Education Committee in London proposes as an experiment for one year to review the medical record of each child in the central schools at the age of 15½ years, and to carry out a detailed medical examination in cases in which the previous history or appearance indicates that such an examination is desirable. At present the children in both ordinary and central schools are examined when approaching the age of 14, but there is no provision for further examination of the children who continue in attendance at the central schools, as about 2,000 of them do, until the age of 16.

A suggestion that "Vitaglass" should be installed in certain of the elementary schools of London is resisted by the Education Committee, which points out that only from the middle of May to September does sufficient ultra-violet radiation penetrate the London atmosphere to make its consideration worth while, that for five weeks of this period the schools are closed, and during the rest of the time the classroom windows are generally wide open. Further, when it is considered that the glass of all windows in London rapidly becomes coated with a layer of fine dust which must obstruct the passage of ultra-violet rays, that only such children as are seated in the direct path of the rays from the sky could be affected, and that even these children would be benefited only in so far as the rays fell upon the unclothed portions of their bodies, it is held to be more important in London to continue the policy of open-air methods of education whenever possible and to draw the attention of the teachers to the benefits of the widely opened window.

SURREY TUBERCULOSIS SANATORIUM.

Lord Ashcombe, Lord-Lieutenant of Surrey, laid the foundation stone on May 11th of the central block of the Surrey County Council Sanatorium, at Milford. Although the scheme for providing residential accommodation in Surrey for the treatment of tuberculous patients was originally drawn up in 1912, the outbreak of the war put an end to the project for the time, and arrangements were made to obtain accommodation in existing institutions elsewhere. It is now proposed to provide 300 beds, including two blocks each containing 50 beds for advanced tuberculosis, and four blocks of 50 beds each for early and intermediate cases. The cost of the sanatorium is estimated at close upon £200,000.

NEW MINISTRY OF PENSIONS HOSPITAL AT LEEDS.

Princess Mary visited Leeds, on May 16th, to open the new Ministry of Pensions Hospital at Chapel Allerton, which has replaced the Beckett's Park Hospital, and will serve Yorkshire, East Lancashire, Lincolnshire, Nottinghamshire, and Derbyshire. The buildings comprise six wards for officers and men, with a total of 200 beds, two operating theatres, an *x*-ray department, a bacteriological laboratory, massage and electrical departments, and an isolation block. There are also workshops for the construction and adjustment of artificial limbs, a large recreation hall, open-air balconies, and extensive grounds. Sir Berkeley Moynihan delivered an address at the opening ceremony, and mentioned that the foundation stone of the first Leeds Infirmary had been laid by Edwin Lascelles, afterwards the first Lord Harewood. Major Tryon, Minister of Pensions, stated that of the 24,000 pensioners receiving treatment under the Ministry, 14,500 were in-patients in hospitals. He referred appreciatively to the valuable work of the Wounded Warriors' Welfare Committee, and added that Leeds was the second greatest centre in the country for the supply or repair of artificial limbs.

CAMERON HOSPITAL, WEST HARTLEPOOL.

The new orthopaedic department of the Cameron Hospital, West Hartlepool, is intended primarily for out-patients, but is so arranged that inmates may be brought into it without difficulty. The nine rooms of the new building have been equipped with the most modern forms of apparatus, including hydro-electrical, radiant heat and light baths, an ultra-violet lamp for general and local radiation, special machines for limb and body exercises, a high power suspension heat lamp, and a thermostatic hot compress. The chairman of the hospital stated at the opening ceremony that under the old cramped and unsatisfactory conditions no fewer than 6,442 treatments had been administered during 1926. Although no further financial appeal was necessary in connexion with the new orthopaedic department, the hospital had an overdraft at the bank, and the general income did not meet the expenditure. During 1926, 937 in-patients had been admitted, and 426 out-patients treated.

LEICESTER ROYAL INFIRMARY.

Improvements at the Leicester Royal Infirmary during 1926 included the opening of the reconstructed *x*-ray department, of which we gave a brief description on May 1st, 1926 (p. 803). In October the open balconies on the three floors of the south-east wing were replaced by glass-enclosed balconies, and the change has been found very beneficial. The new examination rooms which have been added to the casualty department have enabled observation to be kept of sick and injured patients whom it is desirable to retain for a few hours. The possibility of increasing accommodation of this kind and making it available during the night is under consideration. An appeal is being made for £40,000 towards the reconstruction of the central part of the infirmary, which was erected in 1861; it is hoped to construct additional operating theatres and to extend and improve the administrative accommodation. In the annual report for 1926 it is stated that the number of in-patients treated was 5,632, as compared with 5,268 in the previous year; the number of operations had also increased to 4,171, and the out-patients to 146,733. The income had risen from £74,411 to £75,763. Dr. J. D. Slight, one of the honorary physicians, has presented an electro-cardiograph to the institution.

Ireland.

LOCAL APPOINTMENTS.

AT the annual meeting of the Leinster Branch of the British Medical Association the following resolution was passed and the honorary secretary directed to forward it to the Department of Local Government and Public Health:

> The Leinster Branch of the British Medical Association welcomes the recent legislation by which the making of local appointments is, with certain exceptions, vested in a central authority. It is satisfied that this change will tend to prevent nepotism and the exercise of other improper influences in the making of medical appointments. Further, while recognizing the propriety of encouraging promotion in the public service, as is provided for in Section 5 (1) of the Local Authorities Act, 1926—a reform long demanded by the medical profession—the Branch believes that caution is necessary in any action taken under that section. It is urged that the Minister should withhold sanction to any appointment which is not made on grounds of long and meritorious service, with due regard to evidence of attempt at self-improvement, such as post-graduate work and possession of higher qualifications. Otherwise the intention of the Act is likely to be defeated.

EPIDEMIC DIARRHOEA.

A circular letter has been addressed by the Department of Local Government and Public Health to each of the sanitary authorities in the Free State directing attention to the marked increase of mortality from diarrhoea and enteritis of children under 2 years during the third and fourth quarters of 1926. As it is thought not unlikely that this disease may appear in epidemic form and with little warning, sanitary authorities are advised to consult with their medical officers of health as to the means available for controlling an outbreak. In point of incidence diarrhoea diseases are associated in a special degree with urban conditions of domicile, with the second six months of the year, and with the second and third months of infant life. They are attributable to food contamination arising from disregard of cleanliness in the household and in municipal sanitary arrangements, from the agency of flies as carriers of infection, and from an unwholesome milk supply. Young children suffer particularly from the latter cause when they are changed from breast-feeding to artificial diet. The circular concludes as follows:

> It is important not only to insist on domestic cleanliness, but also to secure that all accumulations of dust, refuse, or filth about the dwellings are removed at frequent intervals. This applies to the contents of privies, manure heaps and ashpits, and to the cleansing of yards, passages, and streets. In this way the breeding of flies, which are such potent agents in polluting food and drink, may be prevented. All practical measures for the destruction of house-flies, in order to prevent their access to food, should be taken. Strict attention to the observance of cleanliness (hands and clothing) on the part of milkers, and thorough cleansing of utensils used for containing milk, should be enjoined. Receptacles for the storage of milk in dairies and in the homes of consumers should be protected with muslin or other covering. A weekly record of bacterial content of the milk supply of urban areas would constitute a valuable index of the extent to which satisfactory methods of production and handling are adopted. The Minister would suggest that where a child welfare scheme is in operation the organization should be utilized for giving suitable warning and instruction to mothers of young children at sessions of maternity centres and through the domiciliary visits of health visitors and for obtaining information as to the incidence of diarrhoea diseases. As far as possible the leave programme of the health visiting staff should be settled with due regard to the importance of maintaining a full service of experienced visitors during the period when an attack of summer diarrhoea may be apprehended. If arrangements exist for providing milk to expectant and nursing mothers and young children, the sources of supply should be inspected with a view of guarding against possible contamination, and the subsequent methods of distribution should be regulated with strict attention to cleanliness.

MEDICAL PRACTITIONERS BILL (FREE STATE).

The Medical Practitioners Bill has passed through all its stages in the Dail and Senate.

Union of South Africa.

[FROM OUR CORRESPONDENT IN CAPETOWN.]

A PUBLIC HEALTH AMENDMENT BILL.

IN the House of Assembly, on March 23rd, the Minister of Public Health (Mr. D. F. Malan) moved the second reading of the Public Health Act (1919) Amendment Bill. Its principal provisions relate to the training of midwives, the notification of venereal diseases, and to vaccination. The bill provides that the responsibility for the training of midwives, other than those in service in maternity homes, should rest with the Union Government, and power is taken to make arrangements with the provincial administrations to have these nurses trained in existing maternity and nursing homes. There would be compulsory inspection of these institutions, the idea being that they should be kept up to as high a state of efficiency as possible; and

they would also be registered, but the right to register would be refused if certain requirements were not fulfilled. Moreover, local authorities would be required to keep a list of qualified maternity nurses.

With regard to venereal diseases, the laws existing at present were, the Minister said, very stringent, but a weakness was that only the district surgeons were entitled to bring to the notice of the proper authorities all cases of venereal disease coming under their notice. The ordinary doctors were not obliged to do so, and as the law stood now it was rather dangerous for them to do it, as they might be sued for libel. This bill, however, would make it obligatory on all medical practitioners to bring to the notice of the proper authorities all cases of venereal disease known to them, and cases known to them of patients who refused to be properly treated by medical practitioners. He predicted that if this provision came into operation it would be a very important step forward in dealing more effectively with this dangerous disease.

The provisions as to vaccination were, the Minister said, among the most important. It was desired to amend the existing law to meet the scruples of conscientious objectors. Prior to the consolidating Act of 1919 compulsory vaccination was in force in the Cape Province, the Transvaal, and the Orange Free State, but provision was made in the Natal laws for the exemption of conscientious objectors. When the Act of 1919 was passed the privilege possessed by the conscientious objectors of Natal was taken away from them. Soon after this, owing to agitation in Durban, the then Prime Minister promised that the law would be amended later on, but that meanwhile no prosecutions would be instituted against those who, on conscientious grounds, refused vaccination. The result of this was that there had been a rapid falling off in the number of vaccinations in the Union. In 1920 the number of vaccinations was 523,300, and in 1921 it was 622,000, in 1923 it had fallen to 543,000, in 1924 it was 394,000, and in 1925 it was 364,000. The position to-day was that for the year ended June 30th, 1925, though 76,800 births were registered, only 10,331, or 13 per cent., of the children were vaccinated. The amended bill would make a distinction between the position where there was an actual epidemic outbreak and a threatened epidemic outbreak on the one hand, and, on the other hand, normal circumstances and conditions. In case of an actual outbreak, or a threatened outbreak, no exemption would be allowed to conscientious objectors. When there was an actual epidemic of such a virulent disease as small-pox, the Minister said, private rights or objections must not stand in the way of public safety. The procedure to be followed in normal times would be that conscientious objectors must apply within six months of the birth of a child, or within a certain period if they were themselves not vaccinated, on a prescribed form. They would be required to appear in person before the district registrar of vaccination, and to make an affidavit stating on what grounds they objected to compulsory vaccination. The application and the affidavit would be transmitted to the registrar of vaccination of the province, and it would lie with him to make a decision concerning these objections. In arriving at his decision he would take into consideration whether the applicant for exemption had sufficient knowledge and intelligence to form a judgement, and whether his objection on these or other grounds was genuine. The method which it was proposed to adopt to find out whether an applicant was a bona fide conscientious objector or not was that of sacrifice. In other words, it would be easier for a conscientious objector to comply with the law than to obtain an exemption. The small sacrifice required would be the test whether the objection was genuine or not.

The bill passed its second reading and was set down for the Committee stage.

Plague in Capetown.

No little stir was caused in Capetown when, on April 8th, it was reported that a case of suspected plague had occurred on board the outward bound mail-boat, the *Armadale Castle*, due to sail for Southampton the same afternoon. The patient, a member of the crew, had become ill on April 6th, and was removed to the New Somerset Hospital the following day, where he died very shortly after admission as a case of pneumonia. Smears made from secretion taken at the *post-mortem* examination revealed a bipolar organism similar to *B. pestis*, and a provisional diagnosis of plague was made. Immediately this became known the authorities took every precaution possible. One contact, a member of the crew who had shared a cabin with the patient, was removed to the quarantine station for observation. Members of the medical and nursing staffs of the New Somerset Hospital who had come in contact with the case, and the ward to which he had been admitted, were placed in quarantine. The ship was similarly put in quarantine and moved out to an anchorage in the bay, where she embarked her passengers. All persons who had booked by the steamship were notified before embarkation of what had occurred and given the opportunity not to proceed. All but two, however, decided to make the voyage, and the vessel departed shortly after her scheduled time. On April 11th, as the result of animal inoculation tests carried out by the Government Bacteriological Department, the diagnosis of plague was confirmed. The chief medical officer of health for the Union has stated that there was no need for anxiety as every precaution had been taken from the beginning. He considered the case a sporadic one as no advice of the occurrence of plague at any of the coastal ports visited by the steamer prior to her arrival at Capetown had been received. Since the departure of the boat nothing untoward has occurred on board according to radio messages received, and the contacts in Capetown have remained well.

Southern Peninsula Medical Society: Annual Dinner.

The annual dinner of the Southern Peninsula Medical Society was held at the Marine Hotel, Muizenberg, on March 26th, when some thirty-three members and their guests sat down. The president of the society, Dr. A. J. Ballantine, presided, and the principal guests were Dr. J. A. Mitchell, chief medical officer of health for the Union, and Mr. James Luckhoff, president of the Cape Western Branch of the Medical Association of South Africa (British Medical Association). After the usual loyal toasts had been honoured, Mr. Luckhoff proposed that of the Southern Peninsula Medical Society, and expressed his pleasure at being privileged to be present as the representative of an organization which included among its members practically every practitioner who belonged to the Southern Peninsula Medical Society. Dr. S. F. Silberbauer replied on behalf of the society. The toast of the guests was proposed by Professor A. W. Falconer, Professor of Medicine in the University of Capetown, and responded to by Dr. Mitchell and Mr. W. Floyd, a past president of the Dental Society of the Cape Province. The singing of the National Anthem brought a most enjoyable function to a conclusion.

Influenza Medical Emergency Organization, Capetown.

The following scheme has been adopted by the Council of the Medical Association of South Africa (British Medical Association), Cape Western Branch, for the organization of the medical profession in the event of an outbreak of influenza in Capetown. It stipulates in the first place that medical men in general practice should not be interfered with, and that each individual general practitioner should confine his work as far as possible to the area in which he generally practises. The scheme, briefly outlined, provides for the appointment of (*a*) an organizing medical secretary, (*b*) district medical commandants, and (*c*) emergency medical officers. For the efficient working of the scheme the municipal area has been divided into wards; in medical charge of each, for purposes of administration only, will be a medical commandant selected from among the senior general practitioners residing in that ward. It will be his duty, in the event of an epidemic, to collaborate with his colleagues practising in that ward, and to keep in touch with the

authorities at
Whenever he considers that
work has become too great for those
ordinarily practising in the area he will communicate with
the organizing medical secretary with a view to having
medical assistance supplied. Emergency medical officers
will be recruited from the ranks of specialists, retired
medical men, and senior medical students. They will be
invited to volunteer for service in the event of an emergency
being declared, and will be allotted by the organizing
medical secretary to areas as required, where they will
get in touch with the district commandant of the ward
and work in collaboration with him. The organizing
medical secretary will work out the details of the scheme
and be responsible for compiling a roster of emergency
medical officers. In the event of an epidemic he will
be administrative charge of the organization and will
act in collaboration with the medical officer of health for
the city. The Council of the Medical Association has
advised the municipal authorities that this organization,
together with its organizing medical secretary, will be at
the disposal of the medical officer of health for the city
in the event of an outbreak of influenza occurring. It
should be called into being only in time of real emergency.

Correspondence.

DRUGS FOR SLEEPLESSNESS.

As my experience of the use and value of the group of sedatives is very different from that by Sir William Willcox (May 14th, p. 877), I like to place another point of view before your In my experience, sleeplessness is not merely but one of the most common causes of mental , and therefore in the branch of medicine in work lies it is of the utmost importance to every method of treatment which offers any ccess. With this end in view, twenty years to use medinal, first in the way that Sir llcox advises, that is intermittently, but as were very unsatisfactory from the remedial , I varied my methods constantly until at ime, and for twelve years past, my practice smallest dose that gives good results and then it regularly every night until the mental ealth of the patient has been restored and ix or twelve months, and in some cases for In this way I have advised five or seven al or a tablet of dial to be taken for long have never known any bad results from e drugs. On the contrary I have known ved from serious mental breakdown and nd and body to continue their several

gs for patients of any age, and at the ng the many patients whom I know to ill to be taking these sedatives, under here is a girl of 15 who had a severe ck of mental confusion a year ago. t on five grains of medinal every night, ng it continuously up to the present, so for a further six months. The girl spect and has been so for nine months; oint is to prevent relapse, which is so of this age. For unstable pregnant five grains of medinal to be taken the last two or three months of ix months after the baby is born, nown a mental breakdown in any ried out this advice. In men in nervous system has become over- anxiety, a mental breakdown can rted by a prolonged administration one comes to later life, the mental ssened or interfered with by sleep quality or quantity, and I have time who have taken these drugs under medical advice continuously for several years. A professor in one of the universities, who is over 70 years of age, and who for ten years before he took medinal had suffered from defective sleep with all its concomitant disabilities, has now taken five grains of medinal every night for over five years. He has been sleeping well, and during the last few years has been on a higher level of physical and mental health than had been the case for many years previously.

Space will not permit me to give the many other types of person benefited by taking these drugs. Though no one could use them more freely than I have done, I have never seen any bad effects. I have had the metabolic rate taken and other tests made on patients who have been continuously on these drugs, and the results have all been normal. As with all drugs, a few persons have an idiosyncrasy to them, but I have seen nothing more serious than a simple rash which, when the drug is changed for another, as it must be, quickly disappears. To call these drugs dangerous is, in my experience and in that of many other physicians with whom I have discussed their use, entirely without justification in clinical experience. Further, to so label them is to discourage medical men from using them and to antagonize patients against taking them. To warn a nervous patient that the drug that you are giving him is dangerous is to leave in his mind an anxiety which may go a long way towards counteracting the remedy that you have prescribed.

After spending fifteen years in mental hospitals and seeing the wreckage of humanity, much of which might have been prevented, I have spent the next twenty years of my professional life trying to correct the conditions which lead to mental disorder. Defective quality and quantity of sleep stand high in this list, but, notwithstanding that this is widely recognized, frequently nothing is done to remedy it except to give bromides, often in large doses, the effect of which in these cases is commonly to disturb the digestion and to confuse the mind.

As to addiction, from my own experience and from any evidence that I have been able to obtain from other medical men, this is practically non-existent. There are two classes of persons who might tend to become addicts. The first is the degenerate type who in most instances have always been degenerate and whose excesses are not confined to one drug. Little can be done for these, as the drug-taking is not the cause of their degeneracy but an accident in their life history. The second is even more rare, but he is usually one who suffered from sleeplessness which was ineffectively treated and, when at last he finds something which assures him of sleep, he holds to it in terror of ever again having to go through what he has suffered in the past. Sleeplessness quickly and effectively treated leaves no terrors behind, and I have always found it quite easy to stop the sedatives, even after they have been taken for several years.

I must apologize for the length of this letter, but the importance of the subject emboldens me to ask your indulgence.—I am, etc.,

London, N.W.1, May 20th. MAURICE CRAIG.

WEEDS, CANCER, AND ACIDITY.

SIR,—Some time ago I wrote a letter (BRITISH MEDICAL JOURNAL, August 28th, 1926, p. 405) suggesting a possible field of investigation into the cause and treatment of cancer. I pointed out that there might possibly be a similarity between the causation of weeds and that of cancer, and that the determining factor in the growth of certain weeds, such as plantains, daisies, etc., has been proved to depend on the alkalinity of soil, and that these weed seeds will not germinate in soils of a certain degree of acidity.

My letter has brought me communications from all over the world, and almost without exception the replies that I have received confirm my contentions.

On the other hand, one of the letters suggests that salt may be a cause of cancer, and the writer enclosed a pamphlet giving illustrations to support his theory, but his illustrations might be equally applicable to the absorption of an alkali, such as soap, through the skin.

The germination of the above-mentioned weed seeds is undoubtedly due to the application of alkaline manures to soil, and I suggest it is possible that the prevalence of cancer in man and not in animals may be due to similar causes. At any rate, this is a field of investigation which is worth while inquiring into.

When making tests of soil I have frequently noticed that my skin is markedly acid in reaction, but after washing, unless the soap has been thoroughly rinsed off, it is alkaline. I am not suggesting that people should not wash themselves, but simply that they should use clean water to rinse off the soap thoroughly.—I am, etc.,

Moor Allerton Lodge, Leeds, May 18th. A. MACKENZIE.

THE EPIGLOTTIS IN RESPIRATORY OBSTRUCTION UNDER ANAESTHESIA.

SIR,—Mr. H. Mortimer Wharry's account of the behaviour of the epiglottis in respiratory obstruction under anaesthesia (BRITISH MEDICAL JOURNAL, May 21st, p. 914) must evoke considerable interest among anaesthetists.

With the anaesthetic technique available at present, however, it would seem that certain points in the prevention and treatment of the condition call for some comment.

1. The possibility of laryngeal obstruction during the performance of any operation upon the throat can be ruled out by the use of endotracheal anaesthesia, and this method is applicable in all such operations with the exception of those actually involving the vocal cords.

2. In the treatment of laryngeal obstruction during anaesthesia, from whatever cause, the use of an efficiently illuminated direct vision laryngoscope and endotracheal catheter should surely supersede tracheotomy or laryngotomy. The catheter can be passed into the trachea more quickly than laryngotomy can be performed, and the patient thus spared the knowledge of any untoward occurrence during the operation, not to mention the imposition of an unnecessary wound in his throat.

3. In those cases where respiration has actually ceased, once the patency of the glottis has been restored, the exhibition of 10 per cent. carbon dioxide with oxygen will prove more efficacious than the use of oxygen alone.—I am, etc.,

London, W.1, May 21st. I. W. MAGILL.

SIR,—Mr. Mortimer Wharry, in my opinion, attaches too much importance to the action of the epiglottis. The textbooks on physiology have long ago given up the theory that the epiglottis folds over the orifice of the larynx like a lid during deglutition or at any time during respiration. The orifice of the larynx is closed by muscular contraction of the aryteno-epiglottidean folds, and the whole larynx is drawn up against the base of the tongue by the neck muscles. The epiglottis has frequently been removed for lupus, tuberculosis, and other conditions, with absolutely no interference with deglutition; the saliva does not trickle into the larynx, and no cough is produced. The larynx is closed just as effectually without the epiglottis. This has been observed on many occasions by myself and others.

The function of the epiglottis is to direct air into the nasopharynx and promote nasal breathing. In the horse (and other dumb animals) the epiglottis passes up behind the soft palate, and the horse is essentially a nasal breather. In man, with the development of speech, the epiglottis has become vestigial and of less importance.

There is no muscular mechanism by which the epiglottis is made to act as a lid to the larynx, and even in the swallowing of a bolus of food the epiglottis is in close contact with, and overlapped by, the base of the tongue.

The falling back of the tongue and jaw is still the important cause of respiratory obstruction, particularly during the early stages of anaesthesia before relaxation has occurred. Mr. Wharry, in pulling the epiglottis forward, must of necessity pull the base of the tongue away from the larynx.—I am, etc.,

London, W.1, May 23rd. E. D. D. DAVIS.

THE CONSTITUTIONAL FACTOR IN DISEASE.

SIR,—Dr. Hurst has rendered good service in emphasizing the need for taking more interest in this subject. There are good reasons for thinking that if more attention were paid to the teaching of several of the past masters in medicine, and less attention to the results of highly specialized lines of investigation characteristic of modern times, important advances in practical medicine would be made.

I am sure Dr. Hurst will not misunderstand my attitude if I enter a caveat against the too hasty acceptance of the interesting views and recommendations which his researches have led him to make. I view with apprehension the day when "the brothers, sisters, and children of patients with the A.A.-S.C.D.-H.G. syndrome should be given test meals," and, "if they are found to have achlorhydria, they should, in common with everybody-else in whom the condition is discovered, be advised to take a drachm or more of hydrochloric acid, fasting, in the morning and at lunch and dinner for the rest of their lives." This recommendation is apparently based very largely on the results of one investigation in which four out of one hundred students, regarded as normal, showed a condition of achlorhydria. A little reflection on this fact leads me to doubt the wisdom of founding on it a recommendation along the lines indicated.

My main reason in writing, however, has reference to the conclusion to which Dr. Hurst has been led from his experience of migraine. He states that "in migraine the usual stimulus is ocular, and a very thorough investigation in numerous cases under my care has invariably failed to reveal anything in the nature of alimentary toxaemia, hepatic insufficiency or a toxic idiopathy, which could be held responsible, in spite of the fact that on theoretical grounds these have frequently been suggested as the exciting cause of attacks."

My own experience of numerous cases leads me to an opposite conclusion. It would be interesting to hear from Dr. Hurst the precise nature of the tests which he applied, and the results which satisfied him that he could exclude an alimentary toxaemia as an important etiological factor in that disease.—I am, etc.,

Edinburgh, May 16th. CHALMERS WATSON, M.D.

TRAUMA AS A CAUSE OF AURICULAR FIBRILLATION.

SIR,—I never held the opinion imputed to me by Professor Hay (BRITISH MEDICAL JOURNAL, May 14th, p. 897) that fibrillation in itself is evidence of myocardial damage. As a matter of fact, I do not know a case of fibrillation in which there was no other evidence of a damaged heart. If trauma (overexertion) were able to induce fibrillation in a healthy heart one would expect to see a good many of these cases. Moreover, in my experience there is actually a pre-fibrillating stage recognizable in cases which subsequently develop auricular fibrillation. The characteristic feature of this stage is an exaggerated P (auricular wave) signifying enlargement of the auricle. The exaggerated P is not only found in mitral stenosis but also in other types of heart which subsequently develop auricular fibrillation. My main objection, however, to the statement of Professor Hay and his collaborator is based on entirely different grounds. We are told that the problem is of considerable practical importance because of its medico-legal bearing. Surely from this point of view the terms "apparently normal" and "ordinary methods of examination" are meaningless. From a practical point of view all that matters is: Can or cannot trauma induce fibrillation in a healthy heart? The authors say, "It is certainly true that myocardial damage or some toxaemia is generally present as a predisposing factor." It is therefore admitted on all sides that as a general rule fibrillation appears in conjunction with a damaged heart. As long as it is not proved that in a particular case of fibrillation the heart is healthy, or that trauma has actually induced fibrillation, we must assume that the case conforms to the general rule.

Now in four out of five cases on which the authors rely it has not been established that trauma actually induced fibrillation. The condition might have been there before. In Case IV there is some evidence that trauma has induced fibrillation; but in it there is conclusive proof that we are dealing with a damaged heart. There was a history of a heart attack some years before the trauma which the authors believe was fibrillation; and it is admitted by them that it was a case "predisposed" to fibrillation. (The term "predisposed" can only mean a damaged or abnormal heart in some way.) It is evident that the authors have not been able to produce a single case to support their thesis that trauma may produce fibrillation in a healthy heart.

The evidence that the hearts in these cases were healthy is based on an even more slender foundation. Professor Hay asks us to take it for granted that a case of fibrillation showing extra-systole (Fig. 1), relative preponderance of the left ventricle, slurring of R, etc., comes under the category of an apparently healthy heart! The authors have evidently not had a Wassermann test made in the majority of their cases in order to exclude syphilis. Again, it is repeatedly stated by them that the heart was "slightly enlarged." How pronounced must the enlargement be in order to justify the application of the term "unhealthy"? How do they know that fibrillation was the cause of this enlargement? In short, the authors have not produced evidence that the hearts were healthy, but, on the other hand, there is considerable evidence that they were damaged in some degree.

Professor Hay seems to lay great stress on experimental evidence. As is the case with "apparently healthy" and "ordinary methods of examination," the arguments used in this respect, if they are to hold good, will have to be considerably qualified. In the original paper dealing with the experiment (*Heart*, vol. vii, No. 4, p. 194) Sir Thomas Lewis and his collaborators induced fibrillation in an animal by means of electric stimuli, and the following quotation refers to after-effects; that means to the auricular fibrillation which continued after the stimuli had been withdrawn.

> "On many occasions there will be no after-effects; on very many other occasions there will be a short after-effect lasting a few seconds or perhaps a minute; on rare occasions an after-effect of not many minutes' duration; very rarely of thirty or sixty minutes will be seen."

Now it will be seen that Professor Hay and his collaborator in their paper are dealing with trauma which induces chronic persistent fibrillation. Clearly it follows from this experiment that trauma cannot produce chronic persistent fibrillation in a healthy heart, and it is invariably the tendency, even if fibrillation is produced in a healthy heart, for it to come spontaneously to an end within a short time.—I am, etc.,

Liverpool, May 18th. I. HARRIS.

A RISK OF LIQUID PARAFFIN IN CHRONIC CONSTIPATION.

SIR,—In a memorandum (May 14th, p. 876) Dr. Robert Gibson suggests that the administration of liquid paraffin for chronic constipation may lead to the production of cancer.

In view of the fact that many thousands of people are in the habit of taking paraffin as a daily routine, may I put forward some facts which appear to show that all the evidence is directly opposed to this somewhat disquieting suggestion?

The cancer-producing factor in tar and its derivatives and crude mineral oils—for example, Scottish shale oils and crude petroleum—has been the subject of much intensive and valuable research by Drs. Archibald Leitch, E. L. Kennaway, and others. Dr. Kennaway (*Journal Industrial Hygiene*, 1924, p. 462) has demonstrated:

1. That the cancer-producing factor is completely absent in all the known chemically pure fractions of these products.
2. That it is extremely improbable that the mere fact of continued irritation, in the ordinary sense of the word, is responsible for the production of cancer due to mineral oils or tar and its derivatives. For example, soot is not an irritant except in the sense of cancer-producing properties, while substances such as acridine, which are irritants in the ordinary sense, a innocent of cancer-producing power.
3. Since all the known pure derivatives of tar and crude oils have been thoroughly tested on mice and found to pletely devoid of the cancer-producing property, Dr. K suggests that it is not unlikely that the cancer-producing some quite unknown substance and is present in these su in amounts as small as hormones or vitamins.

Hence if liquid paraffin is devoid of the cancer-pr factor before administration, it may be safely assum it will not acquire it during its passage through the intestine.—I am, etc.,

London, W.1, May 19th. G. B. Dow

THE ESSENTIAL OIL TREATMENT OF CHOI

SIR,—*In the article on the treatment of cholera b* tial oils by Dr. Cannon in the issue of the Jou January 15th (p. 98), he appears to attribute the in of that method of treatment to Dr. Tomb. As a of fact, in an article by me (June 10th, 1922) I d this method for, I believe, the first time.

In that article I gave credit for the idea to a officer of the Public Works Department of Indi advised me about twenty-five years ago to try grat megs and rum, which he described as a specific for He mentioned that he had got the idea from som person who had found it useful also in dysente other bowel complaints. In this connexion I shoul tion that General Collins, A.M.S.(ret.), mentioned of cinnamon oil in enteric fever when, in June I recommended to him the use of the essential oils and cinnamon particularly—in the treatment of ch

In my article I explained that I was, after suc with nutmegs and rum, led to use with great suc *the early stages of cholera, a mixture almost i* with that described as Dr. Tomb's. This formula given on bottles supplied for the past thirty or fort by all the Government medical store depots, un name "Pro-diarrhoea mixture." Shortly after t lication of my article I received, and answered, i from Dr. Tomb regarding the method of administe oils, etc. It was therefore a matter of surprise when nearly two years afterwards I received an circular advising the use of these essential cholera. The source of this advice was an artic pamphlet of the Medical Research Council, which Dr. Tomb's article on the subject in the *Indian Gazette*, and, I think, an American medical (I write from memory).

So far, apparently, no credit has been given to man, whose name I cannot recollect, who thought megs and rum, nor to the medical man who thoug scientific explanation of their action and pointed o *the use of certain more potent essential oils—for e* cajuput, cloves, and cinnamon—was even more effe the treatment of this terrible disease.

I see that Drs. Tomb and Cannon further recomm use of small doses of the essential oils as a proph They may prove beneficial in this respect, a point t only be settled by fairly compiled statistics. Apa the difficulty of their administration as a proph their use might divert attention from measures th proved effective and practicable.—I am, etc.,

Lahore, March 24th. Lieutenant-Colon

DISTRICT ORGANIZATION OF HOSPITALS POST-GRADUATE TEACHING.

SIR,—In the scheme for district organization of facilities which has been foreshadowed by the M of Health it will be a pity if opportunities fo graduate work are not considered along with th aspects of the case.

In the undergraduate schools the teaching arran involve the co-operation and assistance of the stu the general work of the hospital, and this con in no small measure to the success of the hospit a higher plane this relationship might still e qualified practitioners in relation to their local inst

where these are not undergraduate hospitals. It is a commonplace that a doctor's education is never finished, and it may be taken for granted that there are few general practitioners but would admit their desire for a continued and close association with a teaching hospital.

The type of teaching that the post-graduate most needs is probably not the set lecture or course of lectures on various subjects, though these are good up to a point in the form of "refresher" courses; it is rather the team work of hospital life, with its interchange of knowledge and observation, its clash of ideas, and its inexhaustible supply of confidence, that is wanted. In this way our knowledge of medicine is first acquired and is assuredly most easily kept up. Yet it is this type of education which is, by our present methods, most difficult to come by once a man leaves his undergraduate hospital and goes out into general practice.

The undergraduate schools are, of course, always fully occupied. The post-graduate teaching hospitals are few, mostly small institutions, and probably some distance from him, and even in these, unless he can hold a clinical assistantship, he must swallow his pride and be treated like something between a medical student and a complete outsider. What I think he longs for, and needs, is the rights in a hospital which he had as an undergraduate, and to achieve these rights I think he would willingly undertake duties. It may be said that the general practitioner is a busy man, and has no time to undertake these further duties. I suspect that argument is fallacious; in any case, most of us can find time for the things we want to do, and I am convinced that many practitioners would welcome an opportunity of service in a local hospital.

There are other points, too: as regards panel practice, the State might reasonably expect and enable the doctors it employs to spend some of their time keeping abreast of modern medicine. Besides this, the panel doctor on his side undertakes to treat his sick patients, but if, for reasons of his or of theirs, they can be better treated in hospital, he sends them there. Is it unreasonable to suggest that he should follow them up and assist with their treatment in these institutions rather than wash his hands of them? I am speaking broadly, of course; it is not necessary that he should always follow his own individual cases, but rather that, in return for their treatment, he should give some part of his time (say as a clinical assistant) working in the hospital. In this way he would benefit himself, the patients, the institution, and medicine in general.

We talk about medical practitioners engaging in research, and the genius of Mackenzie has already, in a limited field, made this a reality; but we must beware of thinking too much of *research in the sense of set investigations* into individual subjects. The foundation of research is more in the nature of an atmosphere of knowledge and criticism, which every practitioner in his daily work adds to and tests. The set investigations come later, and the discoveries that we acclaim are more in the nature of coping-stones selected and placed in position on an edifice already built. It is this mass and formation of knowledge that we need to strengthen if fruitful research is to go on down the ages, and it is by knitting together the doctors in and through their local hospitals that we shall best do it. What the actual rota of work would be, and how it could be used for the institutions, would be a matter for consideration. That such work can be successfully done is seen in the many cottage hospitals where the local practitioner takes his turn in carrying on the hospital work.

It is, however, in a *reorientation of the Poor Law* hospitals that the greatest opportunity would arise. In these institutions at present the vast amount of clinical material that they contain, though carefully treated, must remain largely uninvestigated, greatly to the loss of the patients, of the institutions themselves, and of the numerous practitioners close outside their walls.

What sort of arrangements for the district organization of hospital facilities will be made remains to be seen; that these are urgently necessary is sufficiently obvious, but unless the use of these hospitals for post-graduate teaching and for bringing *practitioners into closer touch with* institutional medicine is made part of the scheme of reorganization a great opportunity will have been missed.—I am, etc.,

London, W.1, May 17th. T. H. C. BENIANS.

INFLUENZA AND ALBUMINURIA OF PREGNANCY.

SIR,—Mr. R. H. Paramore (May 7th, p. 856) would have been more correct if, instead of stating that he is sorry I "will not allow that compression of the kidney is a cause of albuminuria," he had written "allow that compression of the kidneys is *the* cause of albuminuria in the cases under consideration"—which is all my letter implied.

Mr. Paramore's initial argument was definitely this—the albuminuria of the pregnant woman suffering from influenza must be due to compression of the kidneys, for, (1) only the pregnant woman is affected in this way, and (2) a "terrible" cough adds to the compression produced already by the pregnant uterus. If the compression theory is to be proved, both (1) and (2)—on which the theory is based—must also be proved. As I showed, neither fits in with clinical facts.

Mr. Paramore says that my statement that "nephritis follows influenza oftenest when there is no cough" is "an opinion to be confirmed." Of my last 8 cases of post-influenzal nephritis, 7 followed a very definite tonsillitis which I had observed myself. Any general practitioner who keeps records would probably support this. With reference to Mr. Paramore's objection that *acute nephritis* is very different from acute pyelitis, while admitting that the latter is more of an inflammatory nature than the former, yet I find that both types of case occur at the same seasons and are probably due to the same cause. For instance, I saw between November 3rd and November 18th, 1925, 3 cases of nephritis and 3 of pyelitis. All were due to influenza, and marked tonsillitis was observed in 4 of the cases. I saw but 11 cases during the year. I have had similar "runs" of these cases on other occasions. These were all healthy people, but I have 2 cases of endocarditis whose urine has been smoky during these seasons. One case of endocarditis has passed blood during each of the last three influenza waves. Surely these facts suggest some germ or toxin as the cause of the nephritis.

Mr. Paramore, however, will not admit *that* the "occurrence of . . . nephritis in the non-pregnant, without cough," affects the issue; "for it is by no means certain that these conditions are produced by toxins affecting the kidney." I fail to see how this statement helps the compression theory. He refers to "*other forces* beside cough," but does not specify them.

Some amusement seems to have been caused by my suggestion that accidental haemorrhage may have a connexion with influenza. I have some reason for hazarding the suggestion. If I remember rightly, Browne's recent work included some interesting experiments which showed that the nephritis produced by the coliform group of organisms was most potent in producing thrombosis and infarction of the placenta—the pathological findings in accidental haemorrhage. I remarked on the combination of the influenza toxin and the *B. coli* in my previous letter.

In addition, I have observed during the numerous epidemics of these later years that pulmonary infarction is most certainly a common complication of influenza, and I have evidence that embolism occurs in other organs as well. As already stated, the nephritis cases are probably embolic. In 2 of my cases of post-influenzal nephritis I observed, when the renal symptoms were clearing up, pulmonary infarction, which was followed by the spitting of the bloody-mucous sputa so characteristic of infarction. I have found that pregnant women also get pulmonary infarction during the influenza epidemics, and that the same—as well as pulmonary embolism—also occurs in puerperal women. This may account for the large number of cases of pulmonary embolism after childbirth recently reported in the BRITISH MEDICAL JOURNAL. I have seen 4 such cases since 1920. All this goes to prove that

and thrombosis and infarction
a far cry as Mr. Paramore imagines.—

Aberdare, May 10th. AMBROSE W. OWEN, M.D., B.S.Lond.

"INFAMOUS CONDUCT."

SIR,—Has not the time arrived when it should be brought by the British Medical Association before the General Medical Council that an alteration should be made in disciplinary matters in the form of accusation against a registered medical practitioner? I allude to the term "infamous conduct in any professional respect." The public do not understand what is meant by "any professional respect." The public mind fastens only on the words "infamous conduct" against the accused.

In the navy and army the charge is "conduct unworthy of an officer and a gentleman." Why not in our profession a similar statement—conduct unworthy of a doctor and gentleman? In the public mind the wording in the charge "infamous conduct" carries condemnation before the case is heard.—I am, etc.,

Bournemouth, May 10th. A. HUMPHRY DAVY, M.D.

POST-MORTEM EXAMINATIONS IN GENERAL PRACTICE.

,—I was impressed by Dr. Orton's letter (May 21st, 9) advocating a scheme whereby the making of *post-m* examinations in general practice should become ialty for one particular medical man in a county or division of the country.

neral practitioner suddenly called upon to perform psy is under a great disadvantage; *post-mortem* ations are few and far between for him, and by f this, such a medical witness should not be expected an expert opinion on the cause of death when it is emanded for purposes of accuracy. There should considerations for the citizen, for the relations ead, and also for the doctor who performs the emeanour. It might be, and often is, that the only avail- for obeying the coroner's warrant is in the the deceased. As relations regard anything in e of a *post-mortem* examination with great general practitioner frequently incurs their and also he submits himself to personal risk when he works under cramped conditions.

re, is it fair for a man who is rendering f medical service to the living to proceed to em after doing a necropsy, where there may g. to the conditions under which he worked, acute infection of, say, streptococcus, which to detect or even suspect?

so far as Dr. Orton in his remarks on crime of certificates of death in obscure cases, ith him that there should be a medical inted with pathology, and that such a undertake all the *post-mortem* examina- of counties, and there should be proper a pathologist to do his work.—I am, etc.,

arrowshire, May 23rd. I. H. LLOYD.

C VACCINATION OF THE NEWLY AGAINST TUBERCULOSIS.

nce to the letter of Dr. Major Greenwood, ssue of May 14th (p. 896), I desire to nd's statistical report was printed in as received by me. I have informed he original reports of the medical men vaccine since 1924, preserved in the re open to the inspection of any am, etc.,

A. CALMETTE.

Obituary.

WAREN TAY, F.R.C.S.,

Consulting Surgeon, London Hospital, Royal London Ophthalmic Hospital, and the Hospital for Diseases of the Skin, Blackfriars.

WITH the death of Mr. Waren Tay there has passed away perhaps the last of the men in consulting practice in London who were first general surgeons, but with their general work combined the practice of ophthalmology. There were giants in those days who could excel in more than one branch of medicine. Tay was one of them. Jonathan Hutchinson was another. Tay and Hutchinson were close colleagues and collaborators both in clinical observation and in literary work. Although Tay did not attain the international reputation and fame that was Hutchinson's, yet he made no uncertain mark on ophthalmology. To this day we speak of "Tay's Choroiditis," those fine yellowish spots that appear in the macular region of the fundus of the eye, as one of the signs of senile degeneration; and the discovery of this characteristic lesion was but one of his observations. Besides attaining distinction in the practice of ophthalmology, Tay played no small part as a specialist in diseases of the skin. In his early days he translated into English several foreign medical works, and chief amongst them was Hebra's book on disease of the skin, published by the New Sydenham Society. He was assiduous as a clinician, holding several senior appointments at hospitals. He was first surgeon, and later consulting surgeon, to the London Hospital, where he had received his medical education; he was also surgeon to the Royal London Ophthalmic Hospital, both at the old hospital in Moorfields, and the new buildings in City Road; he was also on the staff of the Blackfriars Hospital for Skin Disease at Blackfriars, and the Queen's Hospital for Children in Hackney Road.

Many as were his hospital appointments, there was no one who was a more conscientious member of a hospital staff than Tay. At Moorfields he was always first at his desk in the out-patient room, and ready to begin seeing his many patients at the stroke of nine o'clock in the morning, thereby setting an example hard for his clinical assistants to follow, who perhaps envied him the short walk that brought him from his home in Finsbury Square to the hospital. He lived and practised in one of the fine old Georgian houses in the city square (now massive office blocks), where formerly were the homes of many consultants before the steady movement to the west of London. But he clave to his old abode until his retirement from practice, to a life of leisure and repose in Croydon, where he died on Sunday, May 15th, at the age of 84. As a man he was shy and retiring, but he had one of the kindliest and gentlest of manners. He was always patient and ready to help a neophyte to understand the intricacies of clinical technique. No trouble was too great for him to undertake. He would even suffer fools gladly, or at least we younger men sometimes thought that this was so.

He attained to the rank of Fellow of the Royal College of Surgeons of England in the year 1869, three years after he had become a Member. In the last issue of the *Calendar* of the College his name comes sixth in chronological order of Fellows, so that there are but five others of the old guard and of greater standing than he was at the time of his death.

N. B. H.

THE LATE PROFESSOR STARLING.

At the meeting of the Académie de Médecine (Paris) on May 10th, the President, Professor Gley, paid a tribute to Professor E. H. Starling, who had very recently been elected a corresponding member. He spoke of his strength of mind, his upright character, his fine spirit, his passionate love for physiology, and his devotion to science. He was, Professor Gley said, a leader of men, who had taken a large part in the development of biology in his own country, and had worthily represented British physiology at international assemblies. His death would be as sincerely lamented by his French physiological and medical colleagues as by his English. At the annual general meeting

of the Lister Institute on May 18th, when Sir James Fowler was in the chair, a vote of condolence with Mrs. Starling was adopted. It recorded the great loss the Institute had sustained by the death of Professor Starling, who for twenty years had devoted to its interests his gifts of a rare ability and a capacity for whole-hearted sympathy with all engaged in the endeavour to promote the advance of science by research. His wise judgement had always proved a safe guide in the conduct of the Institute's affairs.

Dr. NEVILLE THOROLD WOOD, who died on May 14th, aged 69, received his medical education at St. George's Hospital and Paris. He obtained the diplomas M.R.C.S., L.R.C.P. in 1883, the M.R.C.P. in 1892, and graduated M.D.Durham in 1899. A colleague writes: Dr. Neville Wood, who belonged to an old Lincolnshire family and inherited property in that county, was never a very robust man, and, after qualifying, travelled extensively, part of the time as ship surgeon in the P. & O. Co. As a result of his travels he became no mean linguist, knowing French, Spanish, and German. He subsequently settled in Kensington and built up a good high-class practice. He had held the posts of president of the West London Medico-Chirurgical Society, and consulting physician to the Kensington Dispensary and Children's Hospital. Neville Wood will be chiefly remembered for his book on the British health resorts (1912). He had an extensive knowledge of the European waters and climates, and was an active worker in the Section of Balneology and Climatology of the Royal Society of Medicine, of which he became President in 1920 His book on the British health resorts was written in collaboration with a committee of the Section, and contains many articles on the British localities by first-rate authorities. It may be regarded as marking the first step in the co-ordination of the British spas and their recognition as a national asset. Had not his health given way five or six years ago he would doubtless have taken an active part in the post-war developments at the spas in England and in other countries, but his was the task of the pioneer. Men of a strong and determined character like Neville Wood are, inevitably perhaps, a little liable to the "lonely furrow." It is to his honour that in spite of physical weakness, his active and versatile intelligence asserted itself in bold initiation and persevering work.

Dr. SAMUEL EDGAR MARTIN, who died on May 10th, in his 76th year, received his medical education at Queen's College, Belfast, and the London Hospital. He graduated M.D., R.U.I., in 1874, and in the following year obtained the M.Ch. and the diploma M.R.C.S.Eng. In 1877 he was appointed medical officer of Newry Infirmary, from which he retired recently owing to failing health. He was consulting sanitary officer to the Newry Urban and Rural councils, one of the founders of the district nursing society, and a governor of Newry Intermediate School. He was a member of the Ulster Branch of the British Medical Association. Dr. Martin took great interest in Freemasonry, having joined in 1874 St. Patrick's Lodge, Newry, the premier Lodge in Ulster. He rose to be Senior Grand Warden in the Masonic province of Down. He is survived by five sons, four of whom have adopted the medical profession, and by three daughters, one of whom is a nurse.

Surgeon Lieutenant Commander GEORGE AUBREY, R.N., died of pleuropneumonia at Hong-Kong on May 9th. He was the youngest son of Mr. John B. Aubrey of Cowes, was educated at the Middlesex Hospital, took the M.R.C.S. and L.R.C.P.Lond. in 1917, and, after serving as house-physician at Middlesex Hospital, was gazetted surgeon lieutenant, R.N., in January, 1917. He became surgeon lieutenant commander in January, 1923, and had passed for surgeon commander. In May, 1917, he was posted to the monitor M.27, in which he had nearly two years' war service, receiving the medal. In 1919 he was sent to Malta hospital as a specialist in bacteriology and pathology; in 1922 he joined the battleship *Ajax* in the Mediterranean; in 1923 the submarine parent ship *Adamant*; in 1925 the surveying ship *Kellett*, and in 1926 H.M.S. *Tamar*, being also in charge of the dockyard hospital at Hong-Kong.

The following well known foreign medical practitioners have recently died: Dr. K. OOSAWA, emeritus professor in the medical faculty of Tokyo University, one of the first to introduce European methods into medical science in Japan, aged 76; Dr. KARL STARGARDT, professor of ophthalmology and director of the eye clinic at Marburg, aged 51; Dr. A. BEVEROCK, professor of neurology and psychiatry at Prague; Dr. MAX HESSE, extraordinary professor of dermatology at Graz, aged 41.

Universities and Colleges.

UNIVERSITY OF CAMBRIDGE.

AT a congregation held on May 20th the degree of Bachelor of Medicine (M.B.) was conferred on the Hon. C. B. Buckley.

Dr. T. R. Elliott, F.R.S., has been appointed an elector to the Professorship of Physiology until February, 1933, in the place of the late Professor E. H. Starling, F.R.S.

UNIVERSITY OF LONDON.

MEETING OF THE SENATE.

A MEETING of the Senate was held on May 18th, when it was announced that as the result of the semi-general election of members of the Senate the following have been appointed: by Convocation (medicine), Mr. W. G. Spencer, O.B.E., M.S.; by Royal College of Physicians of London, Dr. J. Fawcett; by Royal College of Surgeons of England, Mr. V. Warren Low, C.B., F.R.C.S.; by the Faculty of Medicine, Lord Dawson of Penn, G.C.V.O., M.D., and Mr. H. L. Eason, C.B., M.D., M.S.

Sir William Collins.

In connexion with the retirement of Sir William Collins from the Senate the following resolution was adopted:

> That Sir William Collins be informed that the Senate have learned with great regret of his decision not to seek reappointment on the [illegible] as one of the representatives of the body, and that they desire to place of the distinguished services which to the University.

Chair of Dietetics.

With reference to the anonymou [illegible] £10,000 towards the establishment c' Wander have intimated their desire the same object.

The Bloomsbury Site.

An anonymous offer of £250 has been received as a contribution towards any preliminary expense involved in the preparation of a comprehensive plan for the development of the Bloomsbury site.

Appointments.

The following appointments were made: Mr. D. MacC. Blair, M.B., Ch.B.Glasg., to the University chair of anatomy at King's College, and Dr. G. S. Wilson to the University readership in bacteriology and immunology tenable at the London School of Hygiene and Tropical Medicine. The title of Emeritus Professor of Ophthalmic Medicine and Surgery at University College has been conferred upon Mr. Percy Flemming, M.D., F.R.C.S.

Exhibitions.

The Dunn exhibitions in anatomy and physiology have been awarded to Mr. K. M. Robertson, an internal student of St. Thomas's Hospital Medical School.

QUEEN'S UNIVERSITY, BELFAST.

THE Senate of Queen's University, Belfast, has decided to confer the honorary degree of Doctor of Science upon Sir Berkeley Moynihan, Bt., K.C.M.G., President of the Royal College of Surgeons of England, and upon Professor G. Elliot Smith, M.D., F.R.S., Professor of Anatomy in University College, London.

ROYAL COLLEGE OF SURGEONS OF EDINBURGH.

AT a meeting of the College held on May 17th, Dr. A. Logan Turner, President, in the chair, the following were admitted Fellows:

J. N. Adam, H. G. Armstrong, T. O. Chenoweth, A. L. Clowes, A. H. Coleman, K. A. Gilchrist, M.C., A. C. Gillies, P. N. Gokhale, N. D. P. de V. Graaff, G. M. Gray, J. F. Hackwood, W. K. R. Hamilton, B M. Johns, B. G. Kane, J. J. Kelly, H. Lewis, A. N. McMillan, B T. Rao, M. S. Ross, R. R. Simpson, A. Sourasky, W. C. Wilson, Ruth E. Millar.

The Bathgate Memorial prize, consisting of bronze medal and set of books, was, after a competitive examination in materia medica, awarded to C. J. Poh and D. M. O'Flaherty, who obtained equal marks

SOCIETY OF APOTHECARIES OF LONDON.

The following candidates have passed in the subjects indicated:

SURGERY.—P. V. Bamford, F. W. Crossley-Holland, P. F. Fanaken, S. Goldman, H. M. de Hartog, G. L. McDermott, E. H. Roberts, V. K. Samy.

MEI [illegible] D. Neill,

FOR " " Gillatt,

MID " " M. H.

[illegible] Messrs. P. V. Bamford, H. Gillatt, W. Howard, and L. D. Williams.

Medical Notes in Parliament.

[FROM OUR PARLIAMENTARY CORRESPONDENT.]

THIS week the House of Commons made further progress with the Committee stage of the Trade Disputes and Trade Unions Bill, in the course of which references were made to "boycotts" by medical men. Inquiries are being made to ascertain whether the position of the medical profession is covered by the words "trade or industry" in Clause 1 of the bill.

On Tuesday the Prime Minister announced to the House of Commons that the Government had decided to sever diplomatic relations with Soviet Russia.

The address by Lord Dawson of Penn to members of Parliament on the use of animals in experiments has been postponed owing to pressure of other parliamentary business.

International Labour Conventions.

Brief mention was made last week of the debate raised in the House of Lords, on May 17th, by Lord Arnold, on the use of white lead paint. The statement made for the Government by Lord Cecil of Chelwood as to the obligation of the Government to ratify international labour conventions was important. Lord Arnold had pointed out the two aspects the subject assumed—the technical and the moral. While it was true that a vote for a Draft Convention was not constitutionally binding until the Convention had been ratified by Parliament there was a moral obligation to honour the vote given by its delegates, unless, possibly, circumstances altered very materially after the vote had been given. In the case of the Draft White Lead Convention not only had the Government not ratified, but it had passed an Act to do exactly the opposite of what the Convention, approved by ninety delegates from thirty countries, had laid down. What wonder, when this is done, that someone resigns! Countries would say quite properly: What is the good of sending delegates and technical advisers, at great expense, to try and raise the standard of the workers if, after attaining agreement, the vote really carries no obligation at all? There was reason to fear, if this danger was not recognized, that the pernicious effect would react on treaty obligations of the League of Nations itself.

Viscount Cecil (Chancellor of the Duchy of Lancaster), who replied, described the differences in the machinery for negotiating international conventions of the League and international labour conventions of the International Labour Office, which is a branch of the League. In the latter case the technical obligation, as laid down in Article 405 of the Treaty of Versailles, is to "bring the Draft Convention before the authority or authorities within whose competence the matter lies, for the enactment of legislation or other action." In this respect, therefore, it differed from a treaty obligation seeing that the only technical duty is to present it to Parliament. As to the moral obligation, he agreed with *Lord Arnold that it was not* right that a Government at home should ignore altogether the action which its representative had taken in an international assembly and treat his vote, as representing the Government, as of no account at all. "Personally, I think it a very unfortunate thing when it becomes necessary, not only in this case but in any case, for a Government to take a different view from that which is taken by its representative. . . . It gives an impression of infirmity of purpose and vacillation. No one who has had, as I have, to discuss similar topics before international assemblies since these events took place can have failed to feel that the unfortunate circumstance . . . does to some extent weaken the position of the British representatives who are discussing similar matters before international assemblies. It is obvious that it does."

The debate was continued by Viscount Burnham, who said that but for the steady sympathy and support of this country it was doubtful whether the International Labour Office would be in existence; by Lord Parmoor, who considered that there was a strong moral obligation on this country to go forward with ratification; and by Lord Arnold, who thought that the speech of Lord Cecil was a great advance on the previous position taken up by certain members of the Government.

"Trade Unionism" and Medicine.

During the debate on the Trade Unions Bill, on May 23rd, Mr. Lawson said that anyone who had acted towards the medical profession as Mr. Spencer, the Labour member for Broxtowe, had acted towards the Miners' Federation, would have been driven out of the profession. There was the case of Dr. Axham, which had attracted great attention in the press and among the public, but the British Medical Association, despite public opinion, persisted in its action toward that gentleman. In mining districts, where it was considered that the medical service was not as good as it ought to be, arrangements had been made locally to appoint doctors who were given better salaries than they got elsewhere and better instruments, but in every case the British Medical Association had intervened to prevent these men practising.

Dr. Vernon Davies: Do I understand the hon. member to say that the British Medical Association have definitely threatened these men, or that they have simply offered advice to them not to undertake the work?

Mr. Lawson replied that these professional men had been "advised." They had been brought down to meet representatives of the British Medical Association in the country. They had put their case and defended themselves, and there was not a single case where they had not been driven out and intimidated.

Dr. Vernon Davies said that Mr. Lawson seemed to be suffering under some slight misapprehension in his remarks concerning the British Medical Association. That Association was not a trade union, it was a voluntary combination of certain medical men, but there was no compulsion upon any man to join. He had been a member of the Association ever since he went into practice and had sometimes been opposed to its policy. In that House he had voted against their policy on committees, and yet he had not been penalized in any way, threatened, or interfered with. He had given his point of view and said that, as he believed the Association was wrong, he should vote against them, and he had done so and had not suffered. Cases were mentioned where the British Medical Association had interfered with certain appointments. All that the British Medical Association did was this. They said, "We are an Association of medical men out to protect the interests of the medical men and the public. We think a certain job is worth a certain amount of money. This particular society or company is advertising a job at a rate of remuneration which we think is too low. If you accept it you will be very foolish, because if you stick out you can get more." Suppose a man took it, nothing was done to him. All that the British Medical Association did was to say, "You are satisfied with a lower rate; we cannot interfere, we cannot penalize you, and we cannot turn you out of the Association, nor can we advise anybody to have nothing to do with you."

Mr. Lawson: They drive him out.

Dr. Davies: Not at all; that is where hon. members make a mistake. All that the British Medical Association does is to say, "You are foolish if you are prepared to work for a lesser wage," but it cannot, and does not, penalize that man in any shape or form.

Colonel Watts-Morgan asked Dr. Davies to take it from him that he could give him the case of four doctors who had accepted appointments and had been boycotted by all the medical men in the district, who had refused their assistance in operations and in cases in hospitals. If that was not intimidation, heaven knew what intimidation was!

Dr. Davies said that he was referring to the British Medical Association. It might be that the local doctors considered that a man who accepted this appointment was doing what would bring down the rates of remuneration, and they might say, "We do not approve, and, socially, we will not meet you." But, professionally, they were bound to meet him. If any doctor refused to assist his professional brethren who might request consultation he would not receive the backing of the British Medical Association or of any medical man.

Small-pox.

On May 23rd Sir K. Wood told Captain Garro-Jones that the Minister of Health was of opinion that local authorities had all the necessary powers to safeguard the population from small-pox if adequate use were made by the public of the facilities provided for free vaccination. Further cases had occurred in the Hackney Wick area. The Minister was unable to say when the inhabitants would be free from the danger of infection. Captain Garro-Jones asked if the question of overcrowding would be considered in connexion with preventive measures. Dr. Vernon Davies inquired if Sir K. Wood was aware that overcrowding would not cause small-pox. Sir K. Wood: Yes. Mr. Chamberlain, on May 23rd, said that nine small-pox patients (one male and eight female), whose homes were in the urban district of Hendon, had been removed to hospital. One patient was 8 days old, and the others were aged 8, 15, 16, 21, 23, 37, 42, and 47 years respectively. There were five fatal cases. At the time of infection four of these were unvaccinated and one vaccinated. Of the non-fatal cases, two were unvaccinated and two vaccinated at the time of infection. The vaccinated cases were all vaccinated only in infancy.

He was not aware of any special circumstances which contributed to the fatal results. The source of infection had not been traced.

Sir John Gilmour stated that in the year ended April, 1927, the only locality in Scotland where small-pox cases were notified was Dundee; sixty-one cases were notified there.

Mr. Chamberlain could not say how many of the 694,563 children born in England and Wales in 1926 had been vaccinated, nor could he give the cost of treatment of the 12,922 cases of small-pox notified during the year ended April 2nd last. Save in the case of patients who were suffering from the disease on entering the country, no part of this cost fell on the Exchequer. The cost of public vaccination was approximately £175,000 in 1925-26. Answering Mr. Briant, Mr. Chamberlain said he could not yet say when a report would be issued from the committee appointed to inquire into the methods which are available to diminish or remove any risks which may result from vaccination. Mr. Briant, in his question, described this committee as "appointed to consider the question of post-vaccinal encephalitis."

Shop Acts, 1920 and 1921.

On May 18th the committee which is inquiring into the working of the Shop Acts, 1920 and 1921, heard evidence from Mr. G. A. Foan, on behalf of the Hairdressers' Trade Parliamentary Committee. He said that the long hours of labour before the war affected the health of those engaged in the trade, and it was reported in 1914 that one out of every five hairdressers died of consumption. Since the earlier evening closing there had been a perceptible improvement in the health of the personnel of the trade, but even now they were employed for one hour a day later and longer than the majority of shop workers.

Evidence on behalf of the Retail Pharmacists' Union was given by Mr. H. J. Martin and Mr. G. A. Mallinson. The latter said that chemists had to wait for the evening consulting hours of the doctors. Closing hours of 7 or 8 would not fit the pharmacists, because the doctors did not consult until between 6 and 7, and the chemists had to dispense after that. Mr. Martin said that there was no necessity for a later closing hour on Saturdays than on any other night. Doctors did not make a point of seeing many patients on Saturday nights. The witness added that in most towns there were sufficient chemists living on their premises to provide a service of medicine required after regular hours.

Mr. Mallinson explained that if a chemist was on the national health insurance panel then, even if he did not live on the premises, a notice was posted up showing where medicines could be obtained when the shop was closed.

Replying to further questions as to how the public could get medicine in cases of emergency, Mr. Martin said it must be borne in mind that the doctors knew where the service could be got. The Chairman: Where the surgery hours close at 7, is there sufficient time for a member of the public to get his prescription made up before the chemists' closing hour at 8?—Yes, generally speaking. Witness added that he had never heard of any complaints that the closing hours of chemists, so far as prescriptions were concerned, were too early. No complaints on the subject had been made to the union, nor, so far as he was aware, to the Minister of Health on that subject.

A Vaccination Bill.

Mr. Groves presented, on May 18th, a bill "to amend the law relating to compulsory vaccination." This bill, which is supported by other Labour members, proposes to repeal the compulsory clauses of the Vaccination Acts. No time is available for its discussion this session.

The Policy of the Dental Board.—On May 24th Sir K. Wood, in reply to Mr. Hore-Belisha, said that the real balance of the Dental Board, including the invested general reserve fund, was £20,750. The Minister of Health was informed that the main items of the board's expenditure were grants in aid of dental schools, bursaries to dental students of limited means, and research. The board was not under any statutory obligation to spend money for the benefit of any class, but the Minister was informed that since the formation of the board bursaries awarded to sons of "dentists 1921" had amounted to approximately £10,000, and the sum of £3,850 had been spent on lectures and demonstrations for their benefit. In addition, over £10,000 had been allocated to dental health propaganda and £23,000 to research. "Dentists 1921" participated in the benefit derived from expenditure in these two directions in proportion to their numbers.

Invaliding for Rheumatic Heart Disease.—On May 23rd Dr. Vernon Davies asked the Secretary for Air if any, and how many youths under 21 had been invalided out of the Air Force during the past seven years for which statistics were available, for heart disease, the result of rheumatism during their period of service. He also asked similar questions of the First Lord of the Admiralty and the Secretary for War. Sir Samuel Hoare said that to furnish the statistics asked for would entail the scrutiny of a large number of records, and he did not think that the time and labour involved would be justified. Lieut.-Colonel Headlam said that the officers and men under 21 years of age, invalided from the Royal Navy and Royal Marines during the years 1921 to 1925, for organic heart disease numbered 111 in 1921, 67 in 1922, 23 in 1923, 28 in 1924, and 34 in 1925. It was not known how many of those invalidings were the result of rheumatism, and to ascertain the number would involve a considerable expenditure of time and labour, which would not appear to be justified. Captain King, for the War Office, expressed regret that he was unable to give the information asked for by Dr. Davies, which could only be obtained by examination of the documents of all men invalided during the period. Dr. Davies called Captain King's attention to the statistics given by Lieut.-Colonel Headlam, and asked if the War Office could not prepare its figures in a more get-at-able form. Captain King: I listened carefully to the Admiralty answer, and I noticed that it did not give the information for which the hon. member asked.

First Aid and Safety First.—On May 23rd Colonel Ashley told Dr. Vernon Davies that he had no powers to provide first-aid outfits on the roads of the country in case of accidents. In reply to Dr. Vernon Davies, Sir William Joynson-Hicks said every recruit entering the Metropolitan Police had to secure a certificate of proficiency in first aid. About 90 per cent. of the force possessed certificates. He added, in answer to Mr. Sexton, that the chief inspector of factories reported that the regulations for the provision of ambulances and first-aid appliances at docks were now well observed. No increase of inspectors under the dock regulations could be considered at present. The factory department had taken up with employers' and workers' representatives the question of establishing "safety first" organizations at the ports. He hoped for early practical results.

International Conference on Hydrophobia.—Mr. Chamberlain, on May 23rd, said that the Ministry of Agriculture was represented at the International Congress on Hydrophobia, in Paris, by Dr. W. H. Andrews, the Medical Research Council by Captain S. R. Douglas, and the Ministry of Health by Dr. W. M. Scott. In addition, six representatives attended from British institutes overseas at which antirabic work was specially important. The only expenses entailed to the public funds were travelling and subsistence allowances on the ordinary scale for the three delegates from Great Britain.

Protection Against Gas Attack.—On May 24th Mr. Baldwin told Mr. C. Wilson that the problem of protecting the civil population against gas attack was being closely studied, both in its technical and its non-technical aspects. He could not at the present time particularize the steps taken further than to say that they were directed to securing, in the first place, the provision of an adequate personnel suitably equipped and trained in protective measures, and, secondly, the dissemination at the proper time of full information in regard to the best methods of self-protection.

Deaths from Accident Among Miners.—On May 24th Colonel Lane-Fox informed Mr. F. Hall that during 1925 the death rates from accidents per 1,000 persons employed in mines under the Coal Mines Act in the principal districts were: 1.23 in Scotland, 1.52 in Northumberland (including 38 deaths caused by an irruption of water at Montagu Colliery), 0.75 in Durham, 0.84 in Yorkshire, 1.04 in Lancs, Cheshire, and North Wales, 0.83 in Derby, Notts, and Leicester, 0.84 in Stafford, Salop, Worcestershire, and Warwickshire, 1.25 in South Wales and Monmouth, 1.14 in other English districts, and in Great Britain 1.02. Deaths from diseases scheduled under the Workmen's Compensation Act, which in 1925 numbered 3, had no appreciable effect on the figures.

Research on Vitamins.—On May 24th Mr. Chamberlain, in answer to a question, said investigations of fundamental importance had been made recently in the National Institute for Medical Research at Hampstead, where the production of a vitamin of intense potency had been effected by the action of light upon a known chemical substance in pure form. He was glad to be able to say that this country continued to take the leading position in vitamin research, which it had held throughout. He was informed that much important work upon the various vitamins, including that already mentioned, was in progress in various laboratories, and in large part with the support of public funds administered by the Medical Research Council.

Sodium Silicate to Prevent Plumbo-Solvency of Water.—Sir K. Wood, on May 24th, informed Mr. Morris that the Minister of Health was aware that the process of adding sodium silicate to soft water in order to prevent the solvent action of the water on lead pipes had been adopted in a few districts, mainly on an experimental scale. The quantity of sodium silicate used was so small that the proportion in the treated water was much less than that contained in many natural waters used for domestic supplies. The results of the treatment were being carefully watched, and, upon the information so far available, there appeared to be no reason to apprehend any danger to health or any diminution in the wholesomeness of the water.

Notes in Brief.

Mr. Chamberlain states that from the inception of the National Health Insurance Act till the end of 1926 there were paid in England and Wales, for sickness [illegible] and for disablement benefit £31,000,000, for maternity benefit [illegible] and for additional treatment benefits [illegible]. He is unable to make any statement regarding the recommendation of the Royal Commission on National Health Insurance that benefit should be extended to include a consultant and specialist medical service.

Mr. Chamberlain says that no case has been established for reconsidering the grant made by the Ministry of Health for the maintenance of patients in asylums.

The inquiry by a special inspector of the Home Office into the incidence of lead poisoning in potteries is in progress. It cannot be completed for some little time.

Medical News.

A JOINT meeting of the Guildford Branch of the British Medical Association and the Royal and Southern Counties Branches of the National Veterinary Association was held on May 19th, at the Royal Surrey County Hospital, Guildford, when Professor Hobday opened a discussion on clean milk, in which he recommended the appointment of special boards to deal with milk inspection; these should include the medical officer of health, a veterinary officer of health, and a sanitary inspector. Dr. Nathan Raw said that 10 to 12 per cent. of the milk samples examined contained tubercle bacilli, and that pasteurization was, therefore, necessary at present. Dr. Howell, medical officer of health for Hammersmith, agreed that, owing to the present uncertain condition of milk production, pasteurized milk was the cleanest and safest.

THE ninth Carlsbad international post-graduate course in balneology and balneotherapy will be held from September 8th to 24th. Among others, Dr. H. H. Dale, F.R.S., will deliver a lecture on the theory of insulin action. The course is open to all medical practitioners, for whom full opportunities for studying the local therapeutic institutions will be provided. In connexion with the course a Czechoslovakian visa will be supplied without charge and a 33 per cent. reduction allowed on the State railways. Further information may be obtained from the honorary secretary, Dr. Edgar Gauz, Carlsbad, Czechoslovakia.

THE April issue of *The Fight Against Disease*, the journal of the Research Defence Society, contains an account of Lord Lister's evidence before the Royal Commission on Vivisection in 1875, and his letter to Queen Victoria in the same year. Sir Berkeley Moynihan's recent broadcast speech about Lister is printed, and there is a reprint of the account in the BRITISH MEDICAL JOURNAL of April 9th of the conference with reference to the Dogs' Protection Bill held at the House of the Association. The methods and menace of antivivisection are described, and a short reference is made to the benefits which experimental research has brought to animals. The subscription for membership of the society is 10s., and further information may be obtained from the secretary, Dr. G. P. Crowden, at the offices of the society, 11, Chandos Street, W.1, who will also supply copies of *The Fight Against Disease*, price 6d. net.

A PARTY of 120 members of the Inter-State Post-Graduate Assembly of North America will visit London from June 1st to the 3rd. A series of lectures has been arranged at Dartmouth House on the mornings of the three days, and in the afternoons special demonstrations have been arranged at several London hospitals. Receptions will be held at the Royal College of Surgeons, at 5.30 p.m., on June 2nd, and at the Royal Society of Medicine, at 8.30 p.m., on June 3rd.

THE Council of the Medical School, medical women, and medical women students are arranging a fair at the London (Royal Free Hospital) School of Medicine for Women, 8, Hunter Street, Brunswick Square, W.C.1, in aid of the Centenary Fund of the Royal Free Hospital. It will be opened on Friday, June 10th, by Lady Rayleigh, O.B.E.

THE Fellowship of Medicine announces that on May 30th, at 2 p.m., Dr. A. S. Woodwark will deliver a lecture on diabetes at the Royal Waterloo Hospital, and on the same date and at the same hour Mr. W. McK. McCullagh will give a special demonstration at the Samaritan Hospital; the lecture and demonstration are free to medical practitioners. There will be a series of demonstrations during June at the Royal Eye Hospital, the first of which will be given on June 9th, at 3 p.m., by Mr. Letchworth. The Chelsea Hospital staff will hold a special course from June 8th to 21st, including operative technique and lectures on the diseases of women. From June 8th to 29th there will be an afternoon course at the Central London Ophthalmic Hospital and an operative course will be arranged if desired. From June 13th to 25th a combined course in diseases of children will be held at the children's clinic, the Royal Waterloo Hospital, the National Hospital for Diseases of the Heart, and the Royal National Orthopaedic Hospital. An afternoon course has been arranged at the Blackfriars Skin Hospital from June 20th to July 1st; special cases of interest will be shown on each Tuesday. The Victoria Park Hospital will provide a special course from June 27th to July 9th. The Fellowship of Medicine can arrange for practical courses in anaesthetics and obstetrics and for clinical assistantships in gynaecology. Copies of all syllabuses are obtainable from the Secretary of the Fellowship, 1, Wimpole Street, W.1.

A POST-GRADUATE course on the plastic surgery of the face will be given at the St. Louis Hospital, Paris, from June 15th to July 13th, by Dr. Ferris Smith of Grand Rapids and Dr. Eastmann Sheehan, of New York. The course, which will be given in English, will include lectures, clinical work, and practical instruction in operations on the cadaver. As the entry is limited early application should be made to Professor F. Lemaitre, St. Louis Hospital, 40, rue Bichat, Paris, from whom further information may be obtained. At its conclusion Dr. Chevalier-Jackson will commence a complete course on broncho-oesophagoscopy at the Paris Faculty of Medicine.

The house and library of the Royal Society of Medicine, 1, Wimpole Street, W.1, will be closed on Saturday, June 4th, and Monday, June 6th.

THE May issue of the *Tropical Diseases Bulletin* contains an historical section dealing with early records of research in tropical medicine, including Portuguese contributions in the fifteenth and sixteenth centuries, and ancient reports of plague, malaria, dysentery, leprosy, and scurvy.

LIEUT.-COLONEL JAMES CRAN, M.D., O.B.E., V.D., Principal Medical Officer, has been appointed an official member of the Legislative Council of the Colony of British Honduras.

THE seventh annual Congress of German Oto-Rhino-Laryngologists will be held at Vienna from June 2nd to 4th.

THE nineteenth French Congress of Medicine will be held in Paris from October 10th to 13th under the presidency of Professor Teissier. The subjects to be discussed include the symptomatology of the medical septicaemias; the pathology of the oedemas; and the medical indications and therapeutic value of splenectomy. Further information can be obtained from the general secretary, Dr. M. Chiray, 14, rue Pétrarque, Paris XVIe.

IT was reported to a recent meeting of the Standing Committee of the Office International d'Hygiène Publique that leprosy, which for a number of years had been declining in Bosnia and Herzegovina, is now increasing. In Korea, where there are three or four thousand lepers, treatment with the fatty esters of chaulmoogra oil has produced some results. The curious circumstance was disclosed that three cases of indigenous leprosy have recently been detected in Switzerland. The patients lived in a high lonely valley, which can only be reached on mule-back, and had never been away from home. It is conjectured that some old focus of infection has revived.

THE second part (E–L) of the sale catalogue published by *L'Art Ancien*, Lugano, of early books on medicine, natural science, and alchemy has recently appeared. Each entry is accompanied by an explanatory or historical note in English, and the text is freely interspersed with contemporary woodcuts.

A THREE weeks' summer holiday cruise is being arranged by the *Bruxelles Medical* to leave Havre on August 10th and visit Bordeaux, Lisbon, Tangiers, Algiers, Palma, Barcelona, and Marseilles. The cost will be from £16 upwards; further information may be obtained from Dr. F. F. Imianitoff, 29, Boulevard Adolphe Max, Brussels.

THE number of persons attacked by rabies in 1924 in Germany was 41. It was 63 in 1923, 101 in 1922, and 52 in 1921. Deaths from rabies after inoculation numbered 8 in 1921 (1.44 per cent. of those bitten), 9 in 1922 (0.43 per cent.), 6 in 1923 (0.55 per cent.), and 5 in 1924 (0.34 per cent.), while the deaths among the non-inoculated were 4 in 1921 (8.01 per cent. of those bitten), 9 in 1922 (10 per cent.), 10 in 1923 (22.22 per cent.), and 5 in 1924 (2.36 per cent.).

THERE are at present 32,000 medical practitioners in Italy; 800 medical students become qualified annually.

PROFESSOR EUGEN FISCHER, the well known anatomist of Freiburg, has been appointed director of the Kaiser Wilhelm Institute for Anthropology at Berlin, which is to be opened in September on the occasion of the International Congress on Heredity.

AN institute for the study of tuberculosis has been founded in the Hamburg-Eppendorf General Hospital.

THE Chinese Physiological Society has established a new quarterly periodical entitled the *Chinese Journal of Physiology*, under the editorial direction of Drs. R. K. S. Lim, B. E. Read, and Hsien Wu of Peking, and H. G. Earle of Hong-Kong. The first number, January 1st, 1927, contained papers on the pharmacology of Chinese aconite, the use in anaesthesia of mixtures of ephedrine and procaine, observations on the secretion of the transplanted stomach, and reports of investigations of Chinese pharmacological products. The April issue is larger and includes twelve reports of physiological, pharmacological, and biochemical investigations. The articles appear in English, French, or German, with abstracts in Chinese. The journal may be obtained from the Peking Union Medical College; the annual subscription is £1 2s. 6d.

THE Bureau of the Far East at Singapore reports that for the week ending April 16th there were 18 cases of plague with 16 deaths, 213 cases of cholera with 178 deaths, and 600 cases of small-pox with 241 deaths.

Letters, Notes, and Answers.

All communications in regard to editorial business should be addressed to ***The EDITOR, British Medical Journal, British Medical Association House, Tavistock Square, W.C.1.***

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the BRITISH MEDICAL JOURNAL alone unless the contrary be stated. Correspondents who wish notice to be taken of their communications should authenticate them with their names, not necessarily for publication.

Authors desiring REPRINTS of their articles published in the BRITISH MEDICAL JOURNAL must communicate with the Financial Secretary and Business Manager, British Medical Association House, Tavistock Square, W.C.1, on receipt of proofs.

All communications with reference to ADVERTISEMENTS, as well as orders for copies of the JOURNAL, should be addressed to the Financial Secretary and Business Manager.

The ***TELEPHONE NUMBERS*** of the British Medical Association and the BRITISH MEDICAL JOURNAL are *MUSEUM 9861, 9862, 9863, and 9864* (internal exchange, four lines).

The ***TELEGRAPHIC ADDRESSES*** are:

EDITOR of the BRITISH MEDICAL JOURNAL, *Aitiology Westcent, London.*

FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements, etc.), *Articulate Westcent, London.*

MEDICAL SECRETARY, *Medisecra Westcent, London.*

The address of the Irish Office of the British Medical Association is 16, South Frederick Street, Dublin (telegrams: *Bacillus, Dublin*; telephone: 4737 Dublin), and of the Scottish Office, 6, Drumsheugh Gardens, Edinburgh (telegrams: *Associate, Edinburgh*; telephone: 4361 Central).

QUERIES AND ANSWERS.

MR. F. PEARCE STURM, aural surgeon to the Leigh Infirmary, Lancashire, wishes to consult the English translation of Alexander's *Diseases of the Ear in Children*, but cannot find it in any library. He asks for information.

INCOME TAX.

Deduction for House, etc.

"R.A.M.C.(RET.)" expends £150 in rent and rates, keeps one servant at £50, and uses two rooms (and apparently the garage) for professional purposes; he bought his car six years ago for £250 and is about to replace it at a net cost of £85; he expended £50 on instruments when he began civil practice a year ago.

*** The only safe test as to the amount to be deducted in respect of the house is that it should be reasonable. Assuming that the professional rooms are on the ground floor, we should suggest something between £50 and £75, but it depends on the size, etc., of the house. A somewhat similar proportion should be taken of the cost of the servant, including therein her food, laundry, etc. The amount deductible for the renewal of the car will be £85, or the value of the car when taken into use for the practice a year ago, whichever is the less. No allowance is due for the £50 expended on the provision of the stock of instruments; repairs and renewals will, of course, be deductible.

Motor Car Allowance.

"A. C. R." is informed by his local inspector of taxes that when he claims an allowance for the cost of his car, either by way of depreciation or cost of renewal, it will be necessary for him to produce "accounts" supporting his return.

*** It is, of course, understood that when a special allowance is claimed the Revenue officials have some ground for wishing to have evidence to show that an equivalent allowance has not already been given in one form or another, but the production of accounts hardly seems to be the only way of proving that fact. At the same time the request is one which is difficult to refuse; it is not possible to make an accurate return unless the gross receipts are known and the expenses calculated in detail, and, after all, the inspector is apparently only asking for a copy of statements that *ex hypothesi* have already been prepared.

Expenses.

"W. C. B. S." draws a pension and has bought a share in a partnership, paying his own drug and motor expenses; he asks what deductions he can claim.

*** The pension will, of course, be dealt with by the Government Paymaster, and it should be shown separately in the statement of total income. The partnership income will be included as part of the assessment on the practice as a separate unit, and the necessary joint return will be made by the senior partner. It may be that our correspondent's share will have to be computed wholly or partly according to the earnings of his predecessor—for example, if he bought his share after April 6th, 1926, he will not yet have a full past year's earnings to declare. When it becomes necessary to calculate his own profits for the purpose of the return he should deduct *inter alia* a reasonable sum for professional use of his house, running expenses and depreciation of car, cost of drugs used, telephone, etc. No doubt his colleagues will collaborate with him in this, in view of the necessity for the joint return.

LETTERS, NOTES, ETC.

TRAPS FOR THE UNWARY.

"NEVERMORE" writes: Medical men are not, as a rule, conversant with the many traps that they are liable to fall into in dealing with the numerous circulars they receive through the post. The suspicious nature of some at once put one on guard. But I have been victimized on two occasions, and I should like to warn others.

Some time ago I received a circular pointing out that in the event of a fire occurring on one's premises it would be very difficult to make a claim unless one had a complete schedule of the contents of the house. In response to my inquiry an agent called on me and we discussed the matter, and it appeared that their charge was based on the amount of the valuation, being 1¼ per cent. He suggested that my valuation was probably about £500, and I agreed to have it done, as I thought it would cost me about £5 or £6. A very polite man took two or three days to go over the house, and as a result the total amount was said by him to be £1,500. My bill, therefore, came to over £18, instead of £5 or £6! I refused to pay this amount, and eventually paid £10 to settle.

My next experience was an offer I received from a firm holding themselves out as brokers in connexion with Stock Exchange dealings. They sent me a very full account of the rosy prospects of certain companies in which I could buy shares. I need not put down the whole amount of the purchase money, but I could pay a small amount on each share, and this would give me an option on the shares for three months, or a longer term if arranged. As one of these companies was one that I much fancied, I paid £20 for an option on 200 £1 shares for three months. My impression was that if at the end of the three months the shares were higher than when I bought them, I should get the profit and my £20 back, and if, on the other hand, the shares were lower, I should pay the loss and get my £20 back, or what was left of it. Unfortunately the shares at the end of the three months were exactly the same price as when I bought my option. I received a letter stating that my option was closed and they retained my £20. I am also informed that if the price of the shares had been higher I should still have lost my £20. I have bought my experience; I give this free to my professional brothers.

TREATMENT OF DIABETICS AS OUT-PATIENTS.

DR. C. J. C. EARL (Royal Hospital, Salford) writes: Dr. Lawrence, in his interesting comment (JOURNAL, May 14th, p. 897) on my article under the above heading, claims that most cases of diabetes should be treated as out-patients from the start. I must disagree with him—firstly, upon the grounds that our circumstances are not analogous, and that the daily attendance of patients to which he refers is impossible in a busy provincial hospital such as this. Furthermore, apart from its disciplinary advantages, in-patient treatment allows insulin to be pressed to a degree quite impossible in out-patients, with a consequent increase in the degree of "pancreatic rest" obtained.

BREATHING EXERCISES WITH MOVING ARMS.

WITH reference to the criticism by Surgeon Commander H. Hill, R.N., of the practice of moving the arms during breathing exercises (JOURNAL, March 5th, p. [illegible]
broke Hospital, Wandsworth) writ
co-operation of the vascular system is a necessary part of [illegible]
function of respiration. The output of the right side of the
the rate of the heart beat, and this,
law, varies directly with the amount
nous side. Muscular activity entails
an *increased peripheral distribution of* the blood. When the activity ceases the return of the blood to the heart is improved by steady compression of the veins by the muscles, and, on occasion, by gravity—illustrated best in cardiac embarrassment. Thus the venous input is increased by *steady* leg or arm movements during respiration; the heart beats become more efficient; and the physiological demand for increased oxygenation is better met. This, Dr. Evans considers, is the only real objective of deep breathing. Moreover, the *essential* muscles of respiration benefit by their active contraction against resistance. The slight giddiness caused by simply expanding the chest wall, after exercise, without movements of the limbs, can be experienced by anyone, and witnesses sufficiently to the very important vascular side of respiration. The chest wall is only capable of a certain maximal expansion, which can be achieved despite any opposition by the extra-respiratory muscles.

VACANCIES.

NOTIFICATIONS of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals, will be found at pages 36, 37, 40, 41, 42, and 43 of our advertisement columns, and *advertisements as to* partnerships, assistantships, and locumtenencies at pages 38 and 39.

A short summary of vacant posts notified in the advertisement columns appears in the *Supplement* at page *219*.

Remarks
ON
THE MEDICAL ASPECTS OF HAEMATURIA.*

BY
SIR THOMAS HORDER, M.D., F.R.C.P.,
PHYSICIAN TO ST. BARTHOLOMEW'S HOSPITAL.

THE title of this discussion is rather a misnomer, for it suggests that cases presenting this very common and important symptom can be divided into two classes: medical and surgical. I suggest that the condition of haematuria demonstrates—what I take it we all believe—that, in the first instance at all events, all patients are both potentially medical and surgical: that is to say, they are suffering from pathological conditions, and we do not know at first—sometimes we do not know at last—whether these conditions lie chiefly in the province of the surgeon or of the physician. Several types of haematuria in their causation interest mutually both sides of our work—nephrolithiasis, for example; tuberculosis; urinary tract infection; neoplasm: all of these are conditions which frequently give rise to haematuria, and they all have both medical and surgical bearings.

Still, I think it is clear what is intended by the title, and I do not propose to deal with certain forms of haematuria which are essentially surgical in their aspects. Trauma, of course, is outside my sphere; so also is neoplasm when it is operable; also calculus of the gross kind giving definite indications for nephrotomy or nephrectomy; again, tuberculosis when the primary condition is renal, as it nearly always is, and radical measures can be employed by way of excision, partial or complete. Further, certain anatomical defects in the vessels and in the position of the organ, when these are diagnosed as being the cause of the haematuria, are outside the sphere of the physician. But I would like to stress the point that haematuria is a symptom which in many cases calls for an approach from both the medical and the surgical aspect in investigation, and very also often in treatment.

As regards definition, I take it that the word as we use it has no reference to microscopic amounts of blood or even to specimens of smoky urine, but to the grosser condition in which blood is present to the naked eye as blood, and at some periods in considerable amount.

I thought it might be useful, as giving me certain types of cases to discuss, if I took a list of cases of haematuria of the kind I have just mentioned—gross, frank haemorrhage—in patients, male and female, who have been in my medical wards, during the past five years, and have therefore been under my own observation, some of them jointly with my colleague Dr. Gow. I have had the cases tabulated—fifty-four in all—in which during the last five years haematuria has been observed either as the main symptom or as a very important and striking symptom. The final diagnoses with regard to these patients were as follow: out of the fifty-four cases, twenty were diagnosed as acute nephritis—nearly one-half the cases, therefore, during these five years have been of this nature—seven were cases of chronic nephritis, four of renal calculus, four of infective endocarditis, three of urinary tract infection, two were suffering from mitral stenosis, and presumably therefore had renal infarction, two were cases of purpura, and two were thought to be prostatic in their origin. There was one of each of the following: Addisonian anaemia, an interesting case of polycythaemia (Vaquez's disease), haematuria following on administration of hexamine in the treatment of encephalitis, and haematuria thought to be due to intensive salicylate treatment. There were also five unclassified cases, and of these five cases I think two come into that ill defined group of haematurias which have been called "essential haematuria."

*The opening paper of a discussion in the Urological Section of the Royal Society of Medicine on April 26th, 1927. The remainder of the discussion is printed at page 1066.

Acute Nephritis.

I will briefly comment upon each type of
haematuria is a common feature. Acut

are all sorts of theories, but none of them
by the bacteriological or other evidence.

Chronic Nephritis.

With regard to chronic nephritis, I do not
anything to add to the accepted views, t
two conditions in which bleeding may occu
chronic parenchymatous nephritis—that is
nephritis with considerable oedema, a tende
uraemic symptoms and cardio-vascular char
not very marked. It seems to take very lit
of subinfection in a patient subject to la
matous nephritis to produce haematuria. T
is the so-called chronic interstitial nephr
kidney, or contracted kidney, with high
and marked cardio-vascular changes. Pati
condition are subject from time to time t
and definite bouts of haematuria, and these
ciated with subinfection. These facts are
study of the cases which have occurred
The term "renal epistaxis" has been r
from Gull's original meaning to a group
"essential haematuria," to which I shall
later. There is no reason why the term "re
should not be applied to a form of kidney
is not associated with marked vascular cha
was not the original meaning of the expres

Some authorities state that if a chronic nephritis is syphilitic in origin bleeding is more prone to occur. To judge by the positive Wassermann reaction in cases of chronic nephritis, if that can be taken as a guide to cases which are syphilitic, there was, in the four cases of which I have notes, no special tendency to bleeding. Nevertheless, it is sometimes said that syphilitic patients tend to a haemorrhagic type of nephritis if the kidney is affected.

Renal Calculus.

With regard to renal calculus, I wonder sometimes if we ought to diagnose renal calculus in the absence of haematuria, assuming that radiological findings are negative. If they are negative and haematuria has not occurred, I think it is questionable whether pain—even pain that seems to be strikingly like renal colic—should be regarded as the result of calculus. In the four cases in this series that I have had under observation, all showed good evidence, either by radioscopy or by nephrotomy undertaken for the purpose of clearing up the diagnosis; but when I come to the cases that are unclassified it is obvious that some may have been due to calculus. I have here a caution to enter, which one of my cases taught me. I overlooked a large calculus in the kidney for a considerable time in the case of a woman who had a gross coliform infection with symptoms of dysuria and with haematuria. She had no renal pain, her kidney could not be felt, and, as it happened, she was not *x*-rayed for a considerable time. The trouble was not a new growth, but a kidney which had been for years disorganized by the presence of a large calculus. It is a thing to beware of in a case in which infection is very easily demonstrable, and is such as to give rise to haematuria, that calculus may be present as well as the infection.

Acute Infections of the Urinary Tract.

That brings me to acute infection of the urinary tract—another group of cases common to both physicians and surgeons. In one of these cases there was a high temperature—104° F.—dysuria, and very copious bleeding. I think that in this country we are aware of the frequency, or at all events the definiteness, of haematuria as an early sign—perhaps the first sign—of coliform infection of the urinary tract; but, all the same, I wonder how many such cases are still thought to be tuberculous. If epididymitis occur, and it sometimes does, that tends to turn the thoughts still more in the direction of tuberculosis. In one of these cases there was a papilloma of the bladder in addition to the infection—a very deceptive case. The woman had had chronic cholecystitis for some time before she came under observation at St. Bartholomew's Hospital. She had haematuria and a urinary tract infection that was quite marked; but Mr. Ball demonstrated by cystoscopic examination that in spite of all this there was a definite papillomatous condition of the bladder, in a small area actually involving the right ureter.

Like the case of calculus already mentioned, here is another possible source of haemorrhage to bear in mind in cases of infection. This reminds me that although I have not a case amongst this series, I have in private seen a case, and have been partly responsible for the demonstration after nephrectomy, of papilloma of the renal pelvis; so that one should be on the look out for the double cause of haemorrhage—papilloma in the pelvis of the kidney or in the bladder, plus the coliform or other infection of the urinary tract.

Prostate.

Two of my cases were labelled prostatic. The patients were men aged respectively 64 and 74 years, and the diagnosis was not entirely on my responsibility. A surgical colleague agreed that the probable cause of the haemorrhage was the prostate—not malignant—rather soft in one case, and with an unusually large intravesical projection. One of these patients—the man aged 64—had a systolic pressure of 100 and a diastolic pressure of 90, so that possibly the hyperpiesis may have increased the tendency to bleeding.

Haematuria Associated with Heart Disease.

I come now to a more definitely medical class of case—haematuria in association with heart disease. There are three forms of heart disease illustrated in my group. The first is septic endocarditis. As I said at the beginning, I am not concerned with the discovery of a few red blood corpuscles in the urine. That is very important, as we all know, in the diagnosis of septic endocarditis—a very early symptom and a very constant symptom, and one which calls perhaps for daily microscopical examination of the urine over a period of a week or ten days. The pathological condition underlying it is well known, and has been described by Gaskell and others. I am not, however, referring to that, but to frank haematuria, the result of embolism. Sometimes the haematuria is unusually prolonged, lasting for weeks, because the embolus is a septic embolus and no doubt sets up a septic focus in the kidney. The condition is usually painless. But in one of my cases of infective endocarditis—a girl of 18—the patient suffered great pain. Her pain was so severe that I thought for some time there must be some other feature than septic infarction. She complained bitterly of the pain, and once or twice it was so great as to require narcotics. But when she died in hospital of cerebral embolism there was nothing found *post mortem* to cause this pain except the renal infarction.

The second form of heart disease in which haematuria occurs is mitral stenosis. There again the cause is renal infarction. In addition to septic endocarditis and mitral stenosis, there is dilated heart. Patients with chronic cardiac dilatation and chronic renal congestion sometimes have quite a large amount of blood in the urine.

Haematuria Associated with Blood Disorders.

I now come to certain blood states. In this series were two cases of purpura, both of them of Henoch's type. They were children, one of whom is still under observation in the hospital, and has been for a considerable time—three months—and is still bleeding. He is a small boy aged 14, whose illness began ten days before he came to hospital, a few days after eating skate. He vomited and had a rash; a very diffuse petechial eruption was present over the arms and legs, with a few spots on the abdomen; he was very listless. On admission his abdomen was retracted, tender, and he had a little pyrexia. At this time there was no blood in his urine, though a little albumin. He gave a history of having had severe abdominal pain on two occasions preceding this, but there was no history of bleeding. He was put on salicylates when admitted on December 27th, 1926. On January 17th, 1927, for the first time, there was a considerable amount of blood in the urine. On the strength of what one knew to be a fact—namely, that salicylates occasionally produce haematuria, the salicylates were stopped, but the haematuria persisted. He also developed oedema of the hands and forearms. The relation of purpura to haematuria is very complex. The kidney may bleed as an expression of the purpuric state; the toxic element causing the purpura may cause the kidney to bleed. But haemorrhages into the kidney themselves cause renal changes very closely allied to, if not identical with, nephritis, so that it is sometimes very difficult to say what is the sequence of events. This boy had large tonsils which it was thought were septic. In another case of Henoch's purpura the patient had three attacks of haematuria with abdominal pain, and then the condition seemed to clear up.

The case of polycythaemia (Vaquez's disease) which occurred in this series was very interesting. It was that of a woman who had been under observation several times in St. Bartholomew's Hospital and in private—a very typical case of the disease. She had had retinal haemorrhages. She also had an arterial block, I thought, in the artery to the left big toe, where there was commencing gangrene which necessitated amputation. Three months after this amputation of the left big toe she was sea-bathing at Eastbourne, and this was followed twelve hours afterwards by an attack of haematuria which persisted for six weeks, indeed up to the time of her death. It was a very intractable haematuria. The loss of blood was so considerable

uco what had been a polycythaemia to figures re just above those of a normal blood count. s before this event Dr. George Graham helped me ier continuous inhalations of oxygen. We demonat the blood state of these patients is not improved easure.

Haematuria due to Hexamine.

series there is only one case of hexamine haemathink there was no doubt about the causation. ase of acute encephalitis. A *post-mortem* examas made eventually. The patient had been given derate dose—20 grains every six hours—and at f the third day there was a profuse haematuria.

Unclassified Cases.

ere five unclassified cases, and I have already I feel sure that one or perhaps two of them put down as "essential haematuria" by those der that there is a group of cases to which we e that provisional label.

these unclassified cases was a patient with of the thoracic aorta; she had a profuse haema- *days before death. The second of the unclassified* ht possibly be regarded as a case of calculus or iasis. Then there was the case of a boy of 18 r. Ogier Ward sent to me from St. Peter's. I *make a diagnosis*, but Mr. Ball was able to say blood came from one kidney only, and not from e know that in some of these cases of haematuria bvious cause it is one side only that bleeds. That rantee, however, that if nephrectomy is performed kidney the other one may not start a similar

rhaps the most typical case of what is termed il haematuria" was that of a man of 33 (looking iterature I find that the cases coming into this up of haematurias are generally between 20 and of age), a cycle maker, who, in 1921, passed blood ine. He was examined with the cystoscope withhing abnormal being found. In November of that had a certain dull, not acute, pain, but nothing , because again nothing further was found. In 1922, he had a short attack of haematuria with symptoms. When he presented himself at the a third time the left kidney was explored, but th negative findings. He bled a little in February, d then nothing happened until he came under on at St. Bartholomew's Hospital in March, 1923. is no event in his past history or present condition st any reason for *this tendency to bleed*. Radiology e negative, he had no dysuria, there were no arterial changes, no hyperpiesis, no albumin or his urine. Conveniently for our purpose, he had k of *haematuria while thus under observation, but* ination of the urine showed merely that there was leal of blood, a few blood casts, but no other casts, condition cleared up rather quickly; within a week e was normal again. I do not know what has d to him since, but that is what I regard as a type which goes by the name of "essential haematuria." easy to say that this is only a group of cases in e *do not know the cause of the haematuria, but it* king fact that in some patients bleeding from the occurs somewhat easily and without obvious cause. tter has been written about a good deal, not much *country, although* Hale-White[1] has published a it.

e seen one case of this type in private. The bleed- so profuse that everybody was alarmed, and said mething must be done; but everything had been cept nephrectomy, and eventually that was done. completely to find anything wrong with the excised and I was particularly keen on one or two points had been brought to my attention: one was the f the pelvis in view of the possibility of minute nata, and the other was the so-called naevoid con- n the kidney substance itself.

[1] *Quart. Journ. Med.*, 1910-11, iv, 509.

Hale-White says of these cases that there is no satisfactory explanation; he uses the term "renal epistaxis" for them, and comes to the conclusion that there are two factors, one an undue case of bleeding from the kidney and the other some toxic state at present unknown.

In my list there does not happen to be an instance, curiously enough, of tuberculosis, or of drugs other than hexamine. The condition has been brought on by use of carbolic ointments and lotions, and there is our familiar friend rhubarb, to which some patients are susceptible. I have also no instance of bilharzia haematuria. I thought, however, it might be useful to take actual cases as a basis for these rather discursive remarks.

An Address

ON

OBSERVATION, CO-ORDINATION OF KNOWLEDGE, AND JUDGEMENT.

ILLUSTRATED BY THE CARDIO-ARTERIAL SYSTEM.*

BY

WILLIAM RUSSELL, M.D., LL.D., F.R.C.P.ED.,

EMERITUS PROFESSOR OF CLINICAL MEDICINE IN THE UNIVERSITY; CONSULTING PHYSICIAN, ROYAL INFIRMARY, EDINBURGH.

WHEN the subject of the address you invited me to give had been settled, I decided, after consideration, that the cardio-arterial system would afford all the illustration my theme required. I was strengthened in this decision by some sentences in one of the Gifford Lectures, which Professor J. S. Haldane of Oxford is delivering at Glasgow University. He is reported as saying, "From its beginnings the mechanistic theory of life was embarked on a hopeless task." "What physiology was progressively revealing was the detail of co-ordinated physiological activity." These quotations are applicable to the system we are to consider. Last century we heard much about the heart as a pump, and the arteries as pipes. I propose to look at them as the co-ordinated system of a *living* pump and *live* tubes, which alter their lumen under a variety of influences, and thereby affect the flow of blood through them.

CO-ORDINATION OF HEART AND ARTERIES.

Beginning with the heart, I ask your attention to the case of a lady who came to Edinburgh a short time ago to consult me.

CASE I.—*Weak Left Ventricle: Constriction of Arteries.*

The patient was a woman, aged 44, the mother of two or three children; she told me that for years she had had a leak at one of her valves. The pulse was 120, regular, small, and cord-like; the brachial artery was in a similar state. There was pulsation between the left sternal edge and the vertical mammary line; the left border of the heart by percussion was beyond that line; the right border was two inches to the right of the sternal edge; the veins, above the right clavicle were greatly distended, and showed a ventricular systolic wave. On auscultation at the apex the first sound was faint and impure. Over the area of pulsation and over the adjoining sternum there was a loud blowing systolic murmur. The pulsation was not "a diffuse apex beat," but was caused by, and the murmur was heard over, the right ventricle. The murmur was therefore tricuspid in origin. The brachial pressure given by the sphygmometer was 130 mm. These observations, co-ordinated with our anatomical and pathological knowledge, showed that the left ventricle was seriously disabled; that the right chambers of the heart and the veins in the neck were distended with blood; that the safety-valve action of the tricuspid had come into play; and that the right ventricle was strong enough to produce a loud murmur as blood was driven back from ventricle to auricle. The pulse rate was 120, the brachial and radial arteries were small and cord-like.

When we have to deal with a weak left ventricle it means that the ventricle does not and cannot empty itself. *The contractions may increase in number, but each* contraction only projects a fraction of the ventricular blood into the aorta; there is, to use Professor MacWilliam's words, "defective cardiac output." The dogma of the

* An address delivered to the Royal Medical Society of Edinburgh.

physiologist is that as a consequence of defective output vaso-constriction occurs, "which tends to keep up aortic pressure." This doctrine of keeping up aortic pressure does not appeal to our clinical judgement when the power of the left ventricle is much lowered. Let me present another view, one which may appeal to clinicians. The aorta and its primary branches constitute a blood cistern, which is kept full by the contraction of the ventricle lifting the weight on the aortic cusps and emptying its contents into the cistern. It must be realized that the pump, which keeps the cistern full, works from below and at a great disadvantage when enfeebled. The cistern, the fullness of which is essential to life, would undoubtedly rapidly empty did the outlets from the cistern retain their normal size; but they become constricted by virtue of possessing a living and active muscular coat, and the fullness of the cistern is assured—up to a point. I submit that this autonomous co-ordination of left ventricle output and arterial constriction is one of the most beautiful arrangements in the body. This is precisely what happened to the patient—namely, a damaged and weakened pump, and a constriction of the arteries easily recognized by the educated finger, yet her so-called blood pressure was 130 mm. Under treatment matters improved. The distension and pulsation in the veins disappeared, the tricuspid murmur ceased, at the apex a loud blowing systolic murmur appeared, the pulse fell to 70, the arteries were twice as large and had lost their cord-like character, and the sphygmometer reading had fallen from 130 to 105 mm. The left heart had regained power, was shooting more blood into the aortic cistern, and the arteries relaxed in virtue of their autonomous co-ordination with cardiac output. The pulse indicated the free outflow from the cistern, and I ask the reader to note that the sphygmometer pressure fell 25 mm.; and we are asked to believe that these records are blood pressure, and indicate heart power.

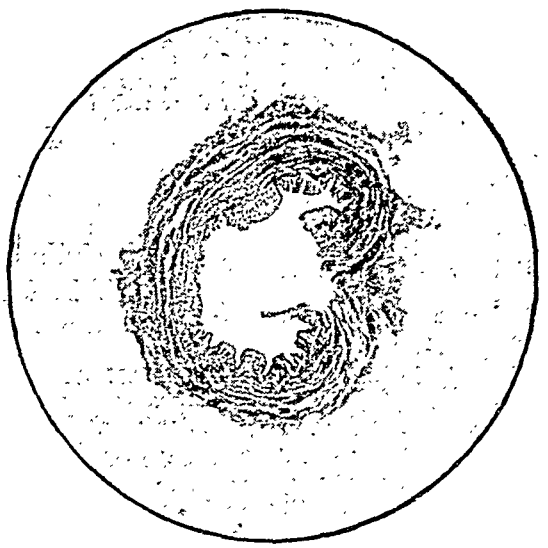

FIG. 1.—Contracted Brachial Artery.

I direct your attention to Fig. 1, which represents a contracted brachial artery; and to Fig. 2, which is a bit of the same artery relaxed (the *post-mortem* appearance of a normal brachial artery). Fig. 1 represents the tightened up artery present in the patient I have spoken of. That that contracted, hypertonic muscular tube, with its thickened wall and much lessened lumen, offers no more resistance to the pressure of the armlet than the artery of Fig. 2, to which, of course, has to be added a normal living degree of tonicity, is a strange belief, and seems to have sprung from the traditional doctrine of the maintenance of aortic pressure even when the left ventricle had lost a large part of its power. Years ago the late Dr. Janeway, in conjunction with Park, experimenting in America with the artery of a bullock, the size of a human artery, came to the conclusion that when hypertonically contracted it required over 60 mm. of pressure to occlude its lumen.

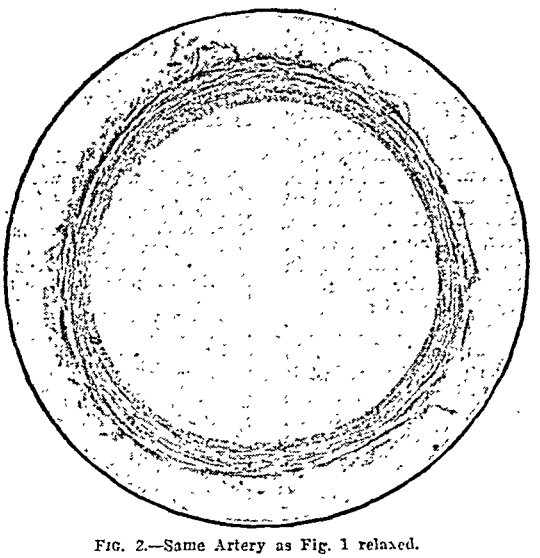

FIG. 2.—Same Artery as Fig. 1 relaxed.

HYPERMYOTONIA IN UNTHICKENED ARTERIES.

I now ask your attention to further clinical manifestations of hypermyotonia in unthickened arteries.

CASE II.—*Hypermyotonia due to Acidosis.*

A man had consulted me when his pressure was 120 mm. Some months later I saw him in the country. He was suffering from insomnia and air hunger; the heart action was irregular, and the arteries were tightened; the sphygmometer pressure was 160 mm. He was given sodium bicarbonate in considerable quantity, and 20 drops of paraldehyde instead of his usual hypnotic. When I saw him the following morning the air hunger was gone, he had slept well, and the pressure had fallen to 135 mm. I suggested that the alkali might be continued as the pressure would probably come down 10 to 15 mm. more. This was clearly a case of hypermyotonia due to acidosis.

CASE III.—*Influence of Emotion on Blood Pressure.*

A man consulted me several times from the end of 1922 into the early months of 1923. The symptoms described to me clearly indicated angina pectoris. The arteries were not thickened, the pulse was soft and regular, the heart sounds were poor. The brachial pressure was about 135 mm.—a normal pressure for over 60 years of age with soft arteries. There was little improvement in the symptoms as I heard them. In April he came into my room after walking some two to three hundred yards from the railway station. His face was pale, he was evidently distressed, he had precordial pain, and he had had to stand still two or three times before he reached my house. His pressure was 158 mm., and his vessels were tightened up. This was clearly the kind of thing he had been describing to me but which I had not seen. He went into a nursing home, where, with rest and some simple treatment, the pressure stabilized to 120 mm. A day or two before he left the home he was sitting up in bed, and offered to show me building plans in which he knew I was interested. This he did, explaining them very clearly and in detail. When he had finished he complained of precordial pain: the pulse was tightened up, and the pressure, which had been 120 mm. before this effort, had risen to 150 mm. Here was an illustration of mental and some emotional stimulation leading to hypertonic arterial constriction and acting back on a myocardium with little reserve of power. I advised him to give up all his country activities, and to confine himself to office and administrative duties. He was an abstainer from alcohol and tobacco. His diet was regulated, a mild laxative was used, and a myocardial tonic taken. He was to avoid everything which threatened to bring on an attack. He has followed out these directions for nearly three years, and has been able to do a great deal of most useful work; but he has still to walk slowly on level ground, and when faced by a slight incline still more leisurely.

These three cases illustrate three causes of arterial constriction in persons with unthickened arteries: (1) lowered cardiac output; (2) blood composition; (3) nervous or emotional influence. In all, when the hypertonia or constriction passed or was overcome, and the left heart recovered, the readings fell; and we are asked to regard them all as blood pressure only.

HYPERMYOTONIA IN SCLEROSED ARTERIES.

Sclerosed arteries are common. Their characteristics are investigated most easily by examining the lower part of the brachial artery, where it is often superficial and its pulsation visible. The finger shows it to be hard and thickened, and often tortuous. The degree of sclerosis, of course, varies in different persons; a tightened up, and therefore hard, normal artery must not be confused with sclerosis.

In Fig. 2[1] the *post-mortem* thickness of a normal brachial artery is shown; but Figs. 3 and 4 represent advanced sclerosis. It will be noted that the thickening is due entirely to the thickening of the middle coat—that is, the muscular coat. This is the kind of artery which, during life, may be felt as hard as a pipe shank; and it was looked upon as a rigid tube. As to its resistance to the pressure of the finger, there was never any doubt until physicians were led away by the claims of the sphygmomanometer, or, as it was first named, the haemodynamometer. This thickened muscular coat is hard; but in many cases it is not a rigid tube, for it can contract and relax, although it has not the range of movement the normal artery has.

At this stage let me point out that the resistance offered by such a structural thickening as is represented in Figs. 3 and 4 cannot be removed; all that remedial measures can effect is to check hypermyotonia, and the power to do this is illustrated in the following cases.

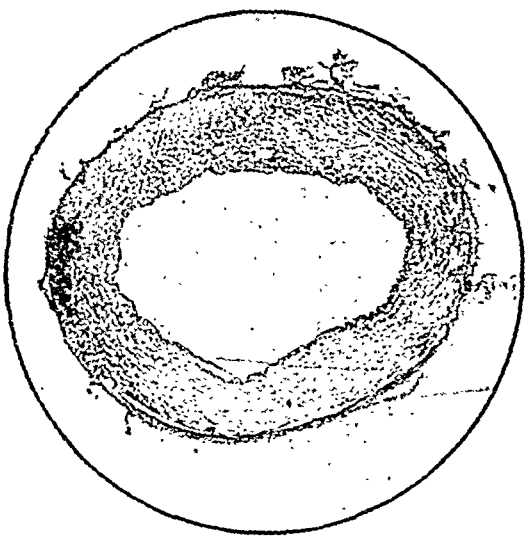

FIG. 3.—Sclerosis of Brachial Artery.

CASE IV.—*Moderate Sclerosis: Hypermyotonia 75 mm.*

A man, aged 58, while seated at his writing table was seized with inability to write, and he could not speak. He was taken home and seen by his doctor soon after arrival. His brachial pressure was 225 mm. He was given a tablet of erythrol tetranitrate. The following morning the pressure was 180, a fall of 45 mm. I saw him two days after his seizure. Speech had improved but was still blurred and it was difficult to make out what he tried to say. The right hand and arm had improved. The radial artery was small and hard, the brachial pressure was 175 mm. The heart sounds were faint. The apex by percussion was in the mammary line. He was given sodium iodide and bicarbonate and tincture of squill. A suitable laxative was suggested. I saw him again seven days later, when the pressure had been 160; my visit put it up to 180. Speech was much improved, but not quite pure, and he was able to write. Thereafter the pressure varied from 125 to 190, but it was promising to stabilize about 150. At that level it could be left, as a certain amount of sclerosis was assumed. Hypermyotonia was responsible for at least 75 mm. There was in this patient a history of habitual constipation, prolonged worry, and considerable tobacco smoking.

CASE V.—*Marked Sclerosis: Hypermyotonia 30 mm.*

A man, aged 68, complained of being drowsy and lethargic, and fit for nothing. I saw him in November, 1923. The brachial artery was hard, thickened, and tortuous; the pressure was 210 mm. He had been taking each morning a purgative which gave him one or more loose motions daily. He was given a laxative which was to be used so as to give one formed motion daily; his diet was regulated, and he was advised to abstain from wine. Two weeks later I saw him again. He had carried out instructions. His unpleasant symptoms had disappeared, he felt quite well, and the pressure was 180 mm. Iodides had no effect in lowering this figure, so they were not persevered with. I saw him last in February, 1924. He had continued well, and the pressure had remained at 180 mm. His death was recorded in August, 1926; but I do not know the cause.

It will be noted that a fall of 30 mm. removed the symptoms complained of, while the structural changes in the arteries made further efforts at reduction unwise.

CASE VI.—*Marked Sclerosis: Hypermyotonia 60 mm.*

A man, aged 54, sent to me at the end of February, 1924, complained of headaches, irritability, and somnolence—he fell asleep when he tried to read, and what he read he forgot in a few hours; he was unfit for work. The pulse was languid and poor. The brachial artery was visible at the bend of the elbow; it was hard, thickened, and tortuous, and the pressure was 240 mm. The heart sounds, including the aortic second, were faint. The urine, acid, specific gravity 1018, contained no albumin or sugar. I had seen this patient ten years before, when the brachial pressure was 170 mm. The outlook now seemed very hopeless, but I suggested cascara and taraxacum as a daily laxative; squill and spirit of nitrous ether; and spare meals. He was a teetotaler. He was sent to me again early in the following May, and I was surprised at the improvement. The drowsiness had gone, and memory had been recovered. The pulse was 84, regular and good, the myocardium had improved and the radial artery had lost its segmented character. The pressure was 180 mm.—a fall of 60 mm., and only 10 mm. above what it had been in 1914.

I need not multiply cases, but there are two others of such great significance that they must be briefly alluded to.

CASE VII.—*Suppression of Urine after Prostatectomy.*

This was a patient with high pressure, who remained well when his pressure was kept about 160 mm. After removal of his prostate he had suppression of urine, and was steadily sinking into coma. The pulse was 140, difficult to count, and felt like a small firm thread. The pressure was 220 mm. With the approval of the surgeon I gave him pituitrin and erythrol tetranitrate—the former to counteract the spasm of renal vessels, which I assumed to be the cause of the suppression, the latter to counteract the constrictive action of pituitrin on the systemic arteries. Within a few hours renal function was re-established; the threatening coma was removed; the pulse was large, slow, and regular; the pressure was 160 mm.

Here there was a fall of 60 mm., with relaxation of arteries and a steady good pulse wave.

CASE VIII.—*Thick Hard Artery; no Radial Pulse; Brachial Pressure 110 mm.*

A man was admitted after a severe attack of pneumonia. He was collapsed and apathetic. There was no pulse at the wrist. There was no heart sound audible anywhere. On examining the brachial artery at the bend of the elbow it was visible, tortuous, and hard, and the pulse could be felt as a mere tap. A pressure of 110 mm. was required to stop the tap. On auscultation no sound was heard as the pressure was applied. Cardiac stimulants were administered, and when I saw him the following morning the pulse at the wrist was easily counted. The pressure was 125 mm.—a rise of 15. How many of the 15 were required to drive the pulse wave from the bend of the elbow to the wrist I do not know.

FIG. 4.—Sclerosis of Brachial Artery.

SUMMARY.

This last case provided a clinical demonstration, more convincing than many experiments, of the positive resistance of a sclerosed living artery, and of the unreasonableness of regarding sphygmometer readings as an index of heart power. Years ago I tested a sclerosed brachial artery, obtained soon after death, and found that it offered a resistance of 100 mm. to compression.[1]

The cases I have reported are examples taken from many. The observations were made in the course of ordinary routine examinations. I have shown constriction of a normal artery, and also the pathological changes which are present in the hard and thickened arteries known as arteriosclerosis. I have given examples of the tightening up of sclerosed arteries, and of the removal of that tightening,

and of the concomitant fall of sphygmometer pressure varying from 30 to 75 or more millimetres. To me the judgement to be pronounced is clear, plain, and inevitable.

CAUSATION.

As to causation, let me refer for a moment to the term "hyperpiesis," introduced to define cases of raised sphygmometer readings in persons without arterio-sclerosis and with no evidence of kidney lesion. They were therefore inexplicable, and were labelled with this name. I have seen many cases of this kind, but I never saw one without palpable constriction of the brachial artery. But the users of this word, and the exponents of what is called "primary and essential hypertension"—hypertension meaning sphygmometer readings—do not recognize that a constricted normal artery, with its living and thickened wall, and lessened lumen, materially affects sphygmometer pressures. I have stated that Janeway and Park gave over 60 mm. for hypertonic contraction in an unthickened artery; the first three cases recorded here gave relaxation readings of 25, 30, and 25 mm.—and that figure after the left ventricle had improved. In Case IV, after the initial fall of 45 mm., the extreme sensitiveness of the arterial wall gave sphygmometer readings which varied from day to day between 120 or 130 and 190 mm. If heart power was being recorded in this case the readings would have indicated an erratic variation of heart power of from 90 to 100 mm. without any indication that the left ventricle was responsible.

As to the influences invoked to account for high pressures, Professor MacWilliam[2] in a recent lecture says:

> "While it is obvious that some powerful agency is at work, the search for definite pressor bodies (from any source) in the circulation has proved to be singularly inconclusive. Clifford Allbutt said: 'Such catch phrases as intestinal toxins, kidney inadequacy, endocrine disorder, and the like are but dust in our eyes.'"

As a clinician who for many years has watched and measured the constriction and relaxation of the arteries examined for clinical purposes, I have learnt the great sensitiveness of this arterial function. The physiological conception that it is mainly, if not wholly, to maintain or regulate blood pressure is much too restricted a view. The arteries respond not only to cardiac output and to nervous influences, but to influences from the alimentary tract, including excess of protein food, wine, tobacco, insufficient removal of hepatic excretion, constipation, and so on. The subtlety of the chemico-vital composition of the blood in different individuals is a fact of which the observant physician has abundant proof, although the laboratory may not be able to explain it or define it by analysis. Biochemistry has done much; but can chemical analysis of the blood determine minor degrees of what is known as acidosis? Yet the clinician removes symptoms, and relaxes hypertonus, by the administration of sodium bicarbonate. So also with treatment directed to biliary secretion and suitable colon emptying; in other cases to the reduction of protein food; in others abstention from wines, and so forth. In all these classes the only feasible explanation is that there is a chemical substance present in the blood which acts directly on the arterial wall. Clinical medicine cannot wait for the advance of biochemical analysis for the confirmation of treatment results. Supposing that large protein feeding acted by increasing the secretion of adrenaline, could biochemistry show its increase in the systemic blood? The same question can be asked with regard to other possible constituents. As a clinician, with some understanding of chemical pathology, I entirely repudiate the doctrine that "such catch phrases as intestinal toxins, kidney inadequacy, endocrine disorder, and the like are but dust in our eyes." Any one of them, or any combination of them, can, and does, cause arterial constriction; and that, as we have seen, means a rise in sphygmometer reading.

The clinical observation which it is most important for us to train ourselves to make is the tightening up of the arteries we examine for clinical purposes. Arterio-sclerosis is the result of more or less continued tightening up in persons whose hearts readily respond to extra strain. It takes years to develop; and it can be checked if tightening is recognized and means are taken to eliminate the factor which is the prime cause. The heart hypertrophy is the response of the heart to the extra strain of driving blood through constricted channels. Kidney changes develop of an interesting and informative type. The renal artery outside the kidney shows the type of change seen in Figs. 3 and 4, whilst the divisions of the artery inside the organ show an irritative and progressive endarteritis. This goes on to the "gouty kidney" of last century, the arterio-sclerotic kidney of a later time.

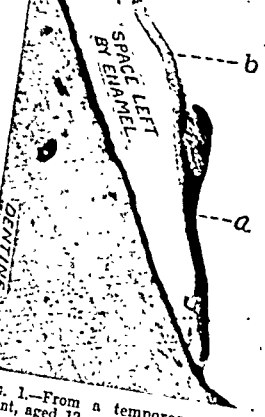
THE HISTOLOGY OF THE PERIODONTAL SULCUS.

BY

J. G. TURNER, F.R.C.S.,

DENTAL SURGEON AND LECTURER ON DENTAL SURGERY.



(From the Research Laboratory of the Royal Dental Hospital of London.)

(*With Special Plate.*)

THE importance of the periodontal sulcus as being the seat of origin of pyorrhœa will be patent to all who have grasped the significance of dental sepsis, yet it is a fact that there are no definite data as to its intimate structure. The chief point at issue has been how is epithelial continuity provided for in the normal condition? Does the gum epithelium attach itself to the tooth, or is there normally a breach of epithelial continuity where the tooth projects? In the latter case the apex of the sulcus would be a serious defect in our defensive armament.

For many years I failed in my efforts to get a section of the normal periodontal sulcus, owing to the dissociation of the tissues which occurs during decalcification and sectioning. A few years ago, however, I hit on the plan of embedding in celloidin before decalcifying, and have been able to get some very useful sections. Having no access to the dead-house I have had to rely on the forceps for my material. Obviously the forceps destroys the lingual and labial parts of the periodontal sulcus, so that my observations relate only to the interstitial part. In many cases a piece of the interstitial gum comes away attached to the tooth, probably more or less dissociated, but possibly intact. I have had a large number of such specimens sectioned, and have been led to the conclusion that interstitially at least there may be, possibly should be, no periodontal sulcus. I have found a considerable number of cases in which the gum is attached directly to the tooth-crown, and the attachment has been firm enough to resist disruption at the moment of extraction. Some of these cases show that there was no possibility of a sulcus (Fig. 1), the gum epithelium being prolonged on to the tooth-crown and fusing with Nasmyth's membrane; others leave a possibility that there was a shallow sulcus, not, however, at the neck of the tooth, but in a position halfway along the crown (Fig. 2). Some sections, again, suggest a potential rather than an actual sulcus (Fig. 3).

The question of epithelial continuity may be definitely answered. There should be no breach until the dentine of the tooth is exposed, or the neck denuded. The gum epithelium may spread over the tooth-crown, much as the skin epithelium over a nail (Fig. 1), becoming continuous with Nasmyth's membrane over a wide area; or it may be continuous with Nasmyth's membrane only at the edge, leaving the fibrous gum to take direct attachment to the tooth-crown (Fig. 5); or for a varying distance it may be split away from Nasmyth's membrane, taking a vital attachment only as the neck of the tooth is approached (Fig. 6); or it may take attachment only to the neck of the tooth—that is, to the cementum (Fig. 7). The first and last two cases leave a possibility of a periodontal sulcus which would develop as the gum epithelium split away from Nasmyth's membrane, possibly as the latter became less vital owing to ageing, or as the gum epithelium peels off

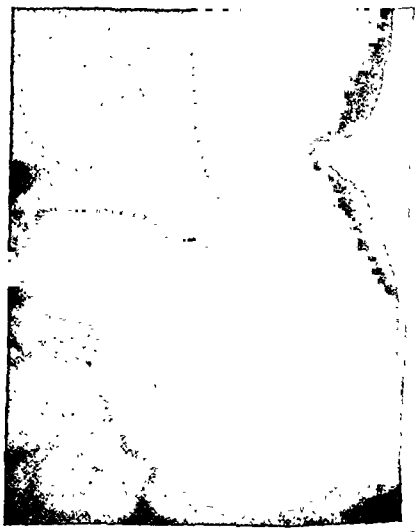

FIG. 1, D.—Ulcer crater has disappeared (December 16th, 1926).

FIG. 2, A.—Large ulcer; confirmed at operation (November, 1925).

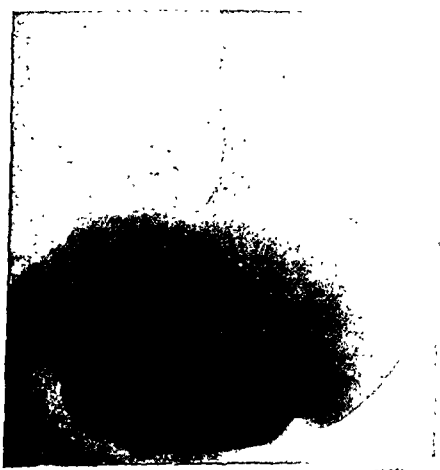

FIG. 2, B.—No *x*-ray sign of ulcer (March, 1926).

the root. The sulcus is thus seen to be a cleft left by the splitting away of gum epithelium from Nasmyth's membrane. When the gum epithelium has split clear away from the whole length of the tooth-crown, or where it never has united with Nasmyth's membrane, it may take a more or less extensive attachment to the root of the tooth (to the cementum).

Thus, though technically there is a breach of epithelial continuity where the attachment of gum to tooth has receded beyond the enamel, practically there is no breach in the defence till the enamel has been worn through to the dentine (by caries or attrition) or till disease (pyorrhœa) has destroyed the epithelial attachment to the tooth.

The nature of the epithelial prolongation which provides for epithelial attachment to the tooth-root is worth further notice.

It is not always present (Fig. 8), and in such cases, if it be due to develop later, it must be provided by the gum epithelium, as was probably the case in Fig. 7, where the gum epithelium can be seen gradually losing its papillary character as it passes along the root. In many cases, however, it seems to have been provided for from the beginning. Most of my sections of this point are taken from temporary teeth, and it is worthy of note that there is no difference in extent of prolongation between teeth about to be shed and those of earlier age (Figs. 3 and 6). There is thus no evidence in the temporary teeth of "continuous eruption." Fig. 7 shows epithelium whose gum origin is indicated by the gradual fading away of the papillary structure; but Figs. 3 and 6 from temporary teeth, and Fig. 2 from a permanent molar, suggest a different origin. A higher magnification (Fig. 4) of the prolongation strongly suggests stellate epithelium—a form of epithelium more likely to arise from epithelium originating from the enamel organ than from the gum. As Figs. 8 and 9 show, there is at the time of eruption an epithelial lining to the tooth-crypt derived from the outermost epithelium of the enamel-forming organ. To allow gum epithelium to take attachment to the tooth this epithelial lining must either atrophy or blend with the gum. I have not been able to decide which, but am inclined to think it generally atrophies, except at its periphery, where it remains capable at need of further growth.

THE HEALING OF GASTRIC ULCERS:

RADIOLOGICAL OBSERVATIONS.

BY

F. G. NICHOLAS, M.B., B.S.LOND., D.M.R. AND E.CAMB.,

ASSISTANT RADIOLOGIST TO THE MIDDLESEX HOSPITAL. RADIOLOGIST TO ST. LUKE'S HOSPITAL, CHELSEA;

AND

ALAN MONCRIEFF, M.D., M.R.C.P.LOND.,

MEDICAL REGISTRAR, MIDDLESEX HOSPITAL.

(*With Special Plate.*)

THE radiological diagnosis of ulcers of the stomach dates from the classical description by Haudek[1] of the characteristic "*niche*" seen in the outline of the stomach after an opaque meal. Much interest has been attached to the disappearance of this "niche" under treatment, and many papers have recently appeared on the subject of the "healing" of gastric ulcers. The terms "healing" and "healed" with reference to gastric ulcer are open to a certain amount of criticism; but it must be accepted that disappearance of a "niche" associated with clinical improvement, disappearance of pain and tenderness, disappearance of occult blood from the stools and vomit, gain in weight, must certainly indicate a *healing* process, as Hamburger[2] has pointed out. If the healing process continues and no recurrence takes place over a period of, say, two years, many observers would consider such cases as "healed." There is certain histological evidence to support this view, and the matter is more fully discussed later.

During the past two years we have investigated a group of cases by *means of repeated opaque meals*, paper we deal with the results. Seventeen selected in which *x*-ray examination disclose "crater" on the lesser curvature of the stom cases occurring at the time when this inve commenced, in which an ulcer was present on or posterior wall of the stomach, have not b since it was found that unless an ulcer could profile in a skiagraph it was very difficult to change in size at subsequent examinations. included in-patients and out-patients, but stances the attendance of the latter for treatn irregular, and no deductions as to the succe of medical treatment are made in this pape such deductions be legitimately made on the forward.

The "double meal" method has been em nights before the examination an ounce of given, and the evening before a light meal is hours previous to the time arranged for radio ounces of barium sulphate are given well bread-and-milk.

At the screen examination notice is taken o of the head of the meal and whether a gast present or not. Occasionally there has been barium in an ulcer crater. Next a mouth barium emulsion is administered, and this "whitewash" the whole of the stomach acc method described by Scott.[3] After a careful e the whole of the stomach by this method the tinues to take barium emulsion until the sto The patient is then rotated, and the stoma from all angles. A skiagram is taken at that shows the maximum size of the crater with of distortion. At the re-examination great that the distance between target and plate, an of the patient, are the same.

Results.

Of the 17 cases in this series all were exa occasions, and 15 on three occasions, the inte the examinations varying from one week to on

TABLE I.—*Results of First Re-examination (I*

(1) "Healed." No evidence of ulceration ...	
(2) "Healing." Definite decrease in size of ulc	
(3) "Stationary." No alteration in size ...	
Average period elapsed since primary examination	

The 11 cases in which no ulcer crater could all clinically free from symptoms, and in good 4 cases in which the ulcer crater was smaller i improving, although the patients were not al from pain. In one of these cases, although *on the lesser curvature had disappeared*, the sistent incisura opposite to the original site and symptoms were still present suggesting tha not complete.

TABLE II.—*Results of Second Re-examina*

(1) No *x*-ray evidence of presence of ulce 11 cases, made up as follows:	
"Healed" cases without recurrence ...	
"Healing" cases now "healed" ...	
"Stationary" case now "healed" ...	
(2) Ulcer again present ("healed" cases relapsed)	
Two cases did not attend; one shown as "he other as "stationary" in Table I.	
Average period between the two re-examinatio half months.	

It will be seen from this table that in 4 cas "healed" in the first examination definite occurred. The clinical symptoms and signs h in all these patients, although at the time re-examination, when no ulcer crater was s 4 cases were clinically free from symptoms. I cases the ulcer crater was definitely larger tha the 11 cases reported as "healed" in Table sented patients in whom the ulcer had remain the whole period of investigation, and the o

whom "healing" had progressed satisfactorily between the two re-examinations.

In view of the great variability in the rate of healing present in this series of cases, quite apart from any question of special treatment, the results were further analysed with regard to length of history, since it might be expected that only ulcers with a short history would heal quickly or at all.

TABLE III.—*Results in Relation to Length of History.*

Length of history—9, 8, 6, 4, 1 (years), 6 months.

Group 2.
Cases found "healed" at first re-examination which were found relapsed at the second re-examination 4
Length of history—15, 4, 4 (years), 9 months.

Group 3.
Cases with ulcer still present at first re-examination which were "healed" at second re-examination 5
Length of history—10, 3, 1, 1 (years), 4 months.

These figures indicate that in our series of cases the healing of an ulcer has very little, if any, relation to the length of a patient's symptoms. It will be seen that the longest "history" in this series was fifteen years, and the shortest four months.

COMMENTARY.

The results here described confirm the value of *x*-ray examinations to check the healing of gastric ulcers. The ulcer may disappear very quickly; in one of our cases examined at weekly intervals it was no longer visible at the end of four weeks (Fig. 1). In another very striking case a huge crater suggestive of a malignant ulcer was discovered on radiological examination. At a subsequent laparotomy the large mass then found was so adherent to surrounding structures that the case was considered unsuitable for surgical removal. On a second radiological examination four months later there was no sign of a crater and the stomach appeared normal (Fig. 2). The "base" of the ulcer shadow was measured in each of our cases, and ranged from 3.5 cm. to 0.5 cm. In this series the size of the ulcer appeared to have very little connexion with the question of whether it would heal or not.

Healing and recurrence have taken place without any sort of treatment in patients who refused to attend regularly, and the "natural periodicity" of the peptic ulcer, as it has been called, has been very well shown. An important point arises from this with regard to the period at which a patient is submitted to radiological examination. By keeping careful clinical records of the patients here described we have found that as a rule pain disappears as the ulcer heals, but it is often gone before the complete disappearance of the crater. Also pain tends to reappear in a patient with recurrence before the ulcer can be shown on radiological examination. Consequently a negative *x*-ray examination between two "attacks" of gastric ulcer or even at the beginning of an attack must not be taken to exclude the existence of an ulcer.

Possible Fallacies.

In reading the literature on the healing of gastric ulcers we have been impressed with the possibility of certain fallacies with regard to the disappearance of the "niche."

Hamburger[2] has pointed out that when the "niche" on the lesser curvature disappears it probably means that scar tissue has filled up the ulcer crater. He holds, therefore, that disappearance of the "niche" and improvement in the clinical condition must occur together and be maintained for six months to two years before the cases are to be regarded as cured. In one group of his cases the "niche" disappeared, but peristaltic waves failed to pass over the ulcer area, indicating that a pathological condition was persisting.

The "niche" may possibly appear smaller because it contains food, as pointed out by F. W. White,[4] or mucus, as stressed by Hollander,[5] but we think that this source of fallacy is largely overcome by the use of the "double meal" technique, since we believe that the first meal acts as a cleanser of the stomach and there is much less risk of mucus or food debris being present in the floor of the ulcer when the second meal is given six hours later. White further stresses the importance of taking all the *x*-ray pictures from the same angle, a point to which we have paid attention. Hollander is inclined to doubt the value of the disappearance of the "niche" as an indication of healing, on account of one case in which healing was reported but haematemesis occurred soon afterwards, and a large chronic ulcer was found at operation. He suggests that an ulcer crater may possibly be obliterated by the pressure of surrounding organs. The probability in such a case is, however, that clinical signs and symptoms would still be present.

A paper on gastric ulcer by Büscher[6] contains certain interesting points in connexion with healing. This paper deals with 643 cases and is a study of the pathology and treatment of the condition. The author states emphatically that radiological observation of the disappearance of the "niche" during treatment is a most valuable estimation of the success of treatment. He stresses certain necessary precautions in technique, but in his wide experience he has not met with many cases where an error was made. Büscher points out, however, that the "niche" may disappear and quickly recur, so that in exceptional cases, such as that reported by Hollander with haematemesis after "healing," an ulcer reported as "healed" may be found at operation. Two recent papers by Crohn, Weiskopf, and Aschner[7] give support to the value of radiological evidence of "healing" of an ulcer. In the first of these they describe a group of 20 cases kept under constant clinical observation. They point out that certain mistakes may be made; a false impression of a "niche" may be produced by persistent peristaltic waves overlying shadows of barium-filled intestines, perigastric adhesions, or localized spasms. They believe, however, that the percentage of errors is very small, and that most objections are theoretical. They point out that whether disappearance of a "niche" means a fully healed ulcer, or the temporary filling of a crater with granulation tissue, can only be settled by examination of a stomach removed at operation from a case in which the "niche" has been shown to have disappeared.

In their second paper they deal specifically with this point, describing two cases of gastric ulcer operated upon. In one of these healing of the ulcer was far advanced, and definitely in progress in the other. Such healing had been associated in these two cases with the regression of subjective clinical symptoms, and the objective evidence of subsistence of the "niche" formation found radiologically. This evidence confirms the previous clinical evidence as to the value of *x*-ray examinations for observing the healing of gastric ulcers, and justifies the conclusion that radiological investigation of "healing" is a most valuable method.

SUMMARY.

1. Seventeen cases of gastric ulcer showing a crater on the lesser curvature have been observed radiologically and clinically over a period of two years.

2. The disappearance and reappearance of the characteristic "niche" have been observed and were associated with remission and recurrence respectively of clinical symptoms and signs.

3. No relation was found either between the length of history or the size of an ulcer and the rate or permanence of healing.

4. Certain fallacies are discussed, but on the whole *x*-ray evidence of healing appears to be of great value.

We are greatly indebted to the physicians and surgeons of the Middlesex Hospital for permission to examine patients under their care.

UNEXPECTED DEATHS IN THE POST-OPERATIVE PERIOD.

BY

A. RENDLE SHORT, M.D., B.S., B.Sc., F.R.C.S.,

SURGEON TO THE BRISTOL ROYAL INFIRMARY, LECTURER IN PHYSIOLOGY TO THE UNIVERSITY OF BRISTOL;

AND

A. D. FRASER, M.A., B.Sc., M.B., Ch.B.,

CLINICAL PATHOLOGIST TO THE BRISTOL ROYAL INFIRMARY, PATHOLOGIST TO THE BRISTOL EYE HOSPITAL, DEMONSTRATOR IN PATHOLOGY TO THE UNIVERSITY OF BRISTOL.

THE material on which this study is based is contained in the accompanying tables.

It will be observed that during the ten-year period, and out of a total of about 16,000 operations, there were seven deaths on the table. In our study of deaths in the post-operative period we have excluded cases of cancer, intestinal obstruction, etc., but not when deaths on the table are considered. Of these seven, two were anaesthetic deaths, four must be attributed to the surgical procedure, and the other was moribund from strangulated umbilical hernia, and died after inhaling only a few drops of ether.

Anaesthetic Deaths.—The first was a man of 48, with an appendix abscess complicated by tuberculous peritonitis. He died during the induction stage. The autopsy showed a flabby degenerated myocardium. The second was a woman of 77, with acute intestinal obstruction, who died during induction. The probable cause was cardiac failure. Open ether, with a little chloroform occasionally during the induction stage, is the almost invariable anaesthetic agent used.

Deaths on the Table from the Surgical Procedure.—The first was a lad in a very feeble condition, with a temperature swinging to 103°, suffering from psoas abscess. He died during the operation. The autopsy showed a flabby heart. Another was a man of 43, with a subclavian aneurysm. He died of haemorrhage. The third had traumatic middle meningeal haemorrhage, and died of bleeding and cerebral compression. The fourth was a baby with bronchopneumonia (temperature 100°, pulse 144). An abscess in the groin was opened without an anaesthetic.

DEATHS IN THE POST-OPERATIVE PERIOD.

The table fully bears out what is well known to the profession, but what the public is slow to learn—that the real dangers of an operation are not during, but after. It will be seen that, except in babies under a year, the risks of surgery are very small indeed until the age of 30 in women and 40 in men. If our statistics had included out-patients and throat cases, a few deaths from the tonsil operation might have appeared to detract from this conclusion. Our figures show no deaths from status lymphaticus. Another ancient bugbear that does not appear is entry of air into a vein. Only one death due to air embolism was noted during the period under discussion, and that was a case of cut throat with partial severance of the external jugular vein. Surgery seems to furnish rather more calamities in men than in women, but this is partly due to a slight preponderance of males operated upon, and especially to the prostate deaths in old men.

It will further be observed that the bulk of the deaths followed operation for three conditions—namely, enlarged prostate, gastric or duodenal ulcer, and gall stones or cholecystitis—and here the principal gains are to be hoped for in the future.

A special table is given of what are described as utterly unexpected deaths, eighteen in number. This includes such disasters as the following:

A man, aged 45, who collapsed suddenly on the fourteenth day after operation for hernia, was thought to be bleeding internally; laparotomy was performed, but nothing found. At necropsy he was found to have had a dilated and fatty heart and atheroma of the aorta.

A man, aged 50, died of tuberculous meningitis eight days after orchidectomy for tuberculous testis.

CONSIDERATION OF THE ASSIGNED CAUSES OF DEATH.

It will be observed that the greatest number of post-operative deaths are attributed to pneumonia, bronchitis, or massive pulmonary collapse (27 out of 109). Of these, 7 followed operation for gastric or duodenal ul 3 were after gall-bladder surgery. As has of remarked, this shows that there is some special c this complication after these as compared with oth tive procedures of equal length and severity. How account for these cases? In 5 or 6 the notes s bronchitis was present before operation, and in we suspect that an appendix was removed in error real diagnosis should have been incipient pneumo have several times given rectal ether instead of a anaesthetic in bronchities or phthisies, but have t pneumonia or collapse of the lung follow—fortun fatal.

It is not probable that sepsis, *per se*, gives ri bulk of the lung complications. Many of those were clean cases; *pneumonias rarely followed opera* cellulitis, pyaemia, and abscesses. Several fact be regarded as possibly acting. The operative proc the upper abdomen probably gives rise to reflex i of the diaphragm, which in its turn is followed by of the lung, and that again by infection. Minut carrying germs may be a factor. The anaesthe some part, no doubt, but not so large a one as recently supposed. Inhalation of vomit may s occur. The subject has been reviewed within year by Featherstone of Birmingham, after stu considerable volume of statistics. He thinks inhi the diaphragm is the principal cause, and the f of lung complications after upper abdomen oper certainly suggestive of this. According to previous gastric lavage and the substitution of inhalation anaesthesia reduce the incidence of po tive pneumonia in gastric cases from 21 to 9 per

And how may we attain the greatest success in *this most dangerous sequel?* First, and principall collection of evidence as to the exact cause. Unt more accurately known very little progress is lik our present information the following rules may down:

1. To avoid as far as possible operating or with bronchitis, or to operate under local ana
2. Careful guarding against inhalation of v
3. As little moving through cold corridors a on the way back to bed.
4. The use of novocain or quinine-urea t the inhibition reflex in upper abdomen op no drainage tubes just under the liver to in descent; no tight binders.
5. After returning to bed to prop the pa when possible, and coax him to draw deep as soon as conscious.

A striking and rather unusual example of suc expected death falling into this class is the follow

A woman, aged 36, had a trifling incision made, under anaesthetic, over a supposed lump in the groin, whic to be nothing. She seemed well afterwards, and on the f got out of bed to go home. She became cyanosed an breathing. The pulse went on beating for a while, then The *post-mortem* examination showed collapse of the ri old-standing bronchitis, and fatty heart.

It seems probable that an examination of the the lung would have saved her.

Pulmonary Embolism.

Contrary to the usual opinion, this seems to b cause of sudden post-operative death. It has oft suspected, rarely found. What had been diagn pulmonary embolism generally turned out to be cardiac failure. Only two cases appear in our series. One of these, occurring on the thirtee after operation for salpingo-oöphoritis, was typica both as to symptoms and *post-mortem* findings. Th following on the eleventh day after a gastro-jeju was atypical, and the clot in the pulmonary art evidently been present unsuspected for some day death. A few cases may have been overlooked of an autopsy, but, if so, the symptoms were n usually associated with this disaster.

It is stated that getting patients up early, or, ir of this, making them move the legs in bed, helps

the thrombosis which determines the embolism. At the Mayo Clinic there were 146 deaths from post-operative pulmonary embolism from 1889 to 1920—that is, about one to every 1,200 operations. It was especially frequent after pelvic surgery (Heard). At the Zürich clinic during the past twenty years, fatal pulmonary embolism occurred in 1.25 per cent. of the operations for uterine myoma (Holzmann).

Cardiac Failure.

Here we approach the most inscrutable, the most tragic, and probably the least preventable of the causes of death in the post-operative period. There is, of course, room for difference of opinion as to classification, but we have blamed the heart for 11 out of 109 deaths, and in 6 of these the event is tabulated as "totally unexpected," on account of the slightness of the operation or the good progress made heretofore.

A few examples typical of various groups may be given.

1. A man, aged 63, underwent Bassini's operation for hernia; he did well till the seventh day, then showed signs of cardio-vascular failure, and died the next day. *Post-mortem* examination showed marked coronary atheroma and myocardial degeneration.

2. A man, aged 58, fell down pulseless whilst crossing the ward nine days after operation for varicocele, and died on the spot after feeble movements of the arms and legs. A dilated left heart was found at necropsy, with flabby muscle and atheromatous coronary arteries.

3. A woman, aged 51, whose gall bladder was drained for cholecystitis without stones, following on repeated attacks of acute cholecystitis with rigors and jaundice. She had a rigor on returning from the theatre. The legs became oedematous on the second day. The temperature never settled to normal; on the seventh day she became collapsed, and later died. At the *post-mortem* examination the liver was swollen and mottled, the ducts dilated and oozing pus, there were stones in the common duct, and patches of ulcerative endocarditis on the aortic valves, which showed ruptures in two places.

The third example can scarcely be called an unexpected death, but the others illustrate how cardiac failure may be either gradual or sudden.

Omitting a few fatalities from endocarditis and pericarditis, we observe that the remaining cardiac deaths include 5 in men, all over 45, and 3 in women. Of the men, 3 followed operation for hernia or varicocele, and one each after gastro-jejunostomy and enlarged prostate. In the first three of these there is no note that any warning of heart weakness had been given. The fourth (the gastric case) did very well for nine days, and then died suddenly. The day before death he vomited without obvious reason and without alteration of the pulse. The next day he suddenly fainted and had "a sort of fit." The pulse disappeared. There was no pain and no vomiting, and no signs of tenderness or rigidity or distension of the abdomen. Finally, the breathing stopped half an hour after the seizure. There was no necropsy. It transpired afterwards that a brother and an aunt and other relatives had also died suddenly, two of them after operations. The fifth patient, who died three days after prostatectomy, had had anginal symptoms, though without signs. The necropsy showed atheroma of the coronary arteries.

Of the women, one was 39, the others older. Two had had attacks of faintness before operation.

Some such patients die probably because an infected area has been stirred up by the surgeon, and a heavy dose of toxin absorbed. In others chloroform may have a share, but probably not ether to any serious extent. The deadly nature of the chloroform-adrenaline combination is or ought to be well known. Several of the cases have occurred just when the patient was getting up again, and the strain has been too much. In a few cases it has seemed possible that post-operative semi-starvation has just turned the scale against them.

How may disaster be averted? In patients over 45 careful inquiry ought to be made into their response to hill-climbing and walking exercise. In cases where there is any ground for suspicion, we should do as little as possible to disturb an infected area, avoid chloroform, feed as well as possible, and exercise special care about getting the patient up again. But the surgeon is apt to be caught in a dilemma when there is some suspicion about the heart, and yet the condition demands intervention. Surgery will always need courage.

Haemorrhage and Shock.

Little need be said under this heading. It is important to realize that catgut knots are apt to be insecure, and it is wise to use a three-cast knot instead of two, and to transfix with a needle if the hold will not be perfectly reliable. In operations on the neck it is well to let the patient cough or vomit just before suturing the skin. If the patient is jaundiced the coagulation time should be taken, and if it is delayed a prophylactic intravenous injection of calcium chloride should be given (10 per cent. in 5 c.cm. doses per 60 kilo body weight, on one, two, or three successive days). If gastro-jejunostomy is being done with clamps we earnestly advocate using an interlocking inner suture line, and taking off the clamps before the conclusion of the inner (through-all-coats) suture line to inspect for bleeding points.

Two of the eight deaths after gastro-jejunostomy succumbed to secondary haemorrhage more than a week after operation. Three were very exsanguinated when operated on, and probably it would have been wiser to let them alone. In one case a patient bled to death after splitting the kidney; it would have been better to remove it (for persistent unilateral idiopathic renal haematuria).

It will be noted that most of the deaths from shock were after gall-bladder surgery. It is probable that there was some underlying defect in the liver. Other fatalities classified here include an amputation at the hip-joint for tubercle, an abdominal nephrectomy, and an Albee operation on the spine, with aspiration of a psoas abscess.

Late Anaesthetic Deaths.

To what extent anaesthetics contributed to some of the deaths from chest complications is a difficult question to which we have already referred, and we shall shortly consider their relation to liver deaths. A woman, aged 47, operated on for interval appendix, died the next day, with cyanosis and dyspnoea. She appears to have inhaled vomit into the trachea. There was no necropsy.

Renal Deaths.

Fourteen fatalities in our series are attributed to this cause. In 7 cases the operation was a prostatectomy; in 5 others the diagnosis was papilloma of the bladder, vesical calculus, and stricture (three). One patient died of anuria after nephrectomy, on the fifth day; this was a case of pyonephrosis and perinephric abscess. The remaining case was a curious one.

A mentally deficient woman, with incontinence of urine and faeces, had a needle in her thigh, and an attempt to remove it under a local anaesthetic failed; it was therefore taken out under ether. The temperature ran up to 102° that night, and she died the next day in a condition of cyanosis and dyspnoea. At the *post-mortem* examination chronic nephritis and a fatty heart were found.

Deaths from renal bankruptcy in urinary surgery, and especially after prostatectomy, are much less frequent than they were, but it seems probable that further improvement can be obtained. The use of the two-stage operation, and the preliminary testing of the kidneys by the urea concentration test and the estimation of blood urea, as well as the routine examination and measurement of the urine, and it may be of the Rowntree-Geraghty and other tests, enable us to avoid some dangerous pitfalls. We now know that the patient may look and feel in good health, and there may be no cystitis, and yet the kidneys may be on the verge of a final breakdown. On the other hand, they are sometimes surprisingly little affected even in a man who has carried a bladder up to his umbilicus for months. My own practice has been to perform the two-stage operation in all cases in which the urea concentration test is below 1.5 per cent. But this does not avert all danger. Out of our 16 deaths following prostatectomy all but two underwent the two-stage operation, 4 dying after the cystotomy and 10 after the removal of the prostate. Not all these deaths were renal, however.

We believe that even very gravely affected kidneys will improve if they are relieved of back-pressure, and then given plenty of time. In two recent cases in the practice of one of us, men who nearly died after the first stage were left for three months wearing a Pezzer tube, and both did well after the prostatectomy. In a third the

percentage of urea before giving any by the mouth was 0.5, and the administration of 15 grams did not raise it in the least. A Pezzer tube was inserted, and after three months the urea concentration test showed 1.1 per cent. The prostate was removed, and he never gave any anxiety.

Liver and Pancreatic Deaths.

Far too many patients have died, as will be seen from the tables, after gall-bladder surgery, and the deaths have often been somewhat mysterious, and unlike those following other operative procedures. Three such fatalities are classed as of "uncertain" cause. Four were probably due to defects of the liver or pancreas, and five occurred under forty-eight hours, and are attributed to "shock," but it seems likely that there was some underlying hepatic deficiency.

Heyd has been in the habit of removing small pieces of liver for the microscope at gall-bladder operations, and has found that there is often a good deal of cell change, fibrosis, etc. He describes three types of death after operations for cholelithiasis. In the first they die in a few hours in a drowsy state, and the operation may have been an easy and simple one. The second type do well for a couple of days, and then develop vasomotor collapse, and may die, or may be saved by proctoclysis and the administration of salines and glucose. In the third the interval before symptoms occur is longer, about five days, and they die in coma. All these are probably due to liver inadequacy. The liver contributes fibrinogen to the blood, so deaths from uncontrollable oozing may also be assigned to hepatic inefficiency.

In our series 9 out of the 20 deaths followed operation either during an acute febrile attack or within a day or two of one. In such circumstances the liver poisoning would be at its worst. Three cases classed as liver deaths were as follows:

1. A woman, aged 30, underwent cholecystectomy during an attack of biliary colic. The gall bladder was very thick and inflamed, but was not adherent; two small stones were removed. The next day she passed into a very collapsed state, with very feeble pulse, temperature 97°, blood pressure (on eighth day) only 60. There were no abdominal signs. The legs became paralysed, and she died on the eleventh day. This seems to belong to Heyd's second type.

2. A woman, aged 62. Cholecystenterostomy was performed for deep jaundice. A lot of oozing followed the operation. She never recovered from the feeble condition, and died on the seventh day. *Post-mortem* examination showed stones in the gall bladder and bile ducts, chronic fibrotic pancreatitis, and much dilatation of the liver ducts and signs of toxaemia.

3. A woman, aged 59, with acute febrile cholecystitis and jaundice, for which cholecystectomy was performed. She did well at first, but the appetite became poor and the pulse very feeble, and she died on the seventh day. *Post-mortem* examination showed a stone in the ampulla of Vater, dilated bile ducts, and flabby dilated heart.

One case classified as a pancreatic death showed fat necrosis at necropsy. The patient died on the twelfth day after cholecystotomy for a "strawberry" gall bladder. The case was admitted as an urgent one. The liver showed parenchymatous infection. There was pus in the gall bladder, but no stones.

The case returned as a liver death apart from gall-bladder surgery was a girl with tuberculous peritonitis, who at necropsy was found to have advanced hepatic cirrhosis.

How, then, is safety to be obtained in gall-stone cases? Certainly, by doing our utmost to avoid operating on febrile patients, or in the presence of an acute attack of biliary colic (unless done on the first day, before the liver has had time to be poisoned). Much is gained if we can tide the patient over for a fortnight or more. Inasmuch as chloroform and ether are well-known to be hepatic poisons, they should be avoided when liver toxaemia is suspected. If we must intervene, let us do as little as possible; if the patient is not jaundiced, it may suffice to drain the gall bladder under local anaesthesia without disturbing adhesions. If jaundice is present, of course more must be done, and the risks in a febrile toxaemic patient are sure to be considerable. With the gall bladder, as with other organs, interval surgery is safe surgery.

The diagnosis of liver toxaemia rests on the following tests: (1) Rosenthal's bromsulphalein test; (2) the laevulose tolerance test; (3) van den Bergh's test for the detection of latent jaundice. In several recent cases the laevulose test has warned us to wait a little longer before operating on patients who have recently had an acute attack, and the operation findings have shown that the delay was wise.

Other Causes.

The remaining causes of unexpected death in the post-operative period do not call for much remark.

A patient died of peritonitis after cystotomy for enlarged prostate, without any direct leakage, by infection tracking up in the layers of muscle. Two cases developed meningitis: one, a man, after orchidectomy for tuberculous testis; and the other, a child, after removal of the cuboid for talipes (in the latter the meningitis was not verified *post mortem*). Three cases of persistent vomiting after gastro-jejunostomy were presumably due to vicious circle or faulty lie, as there was no evidence of leakage.

As an example of a strange fatality after operation the following may be given:

A woman, aged 53, was sigmoidoscoped, and piles were ligatured under a general anaesthetic. A little bronchitis was present. During the night the pulse dropped to 50, and there was extreme feebleness. She died twenty hours after the operation. At the necropsy no injury to the bowel was found, but it "showed signs of absorption of toxins," and there was "slight peritonitis"; the lungs were congested, and liver and heart showed slight fatty degeneration; there was atheroma of the aorta and right coronary artery, and old pericarditis; the heart muscle was weak. The spleen and kidneys were toxaemic. Death was attributed to peritonitis and heart failure.

The tables refer to cases during the ten years 1915 to 1924 at the Bristol Royal Infirmary, under six surgeons, also the private practice of one of us (A. R. S.) during the same period. They include all deaths on the table, from whatever cause; all deaths within fourteen days of operation, amongst in-patients in the surgical wards, or in a nursing home or private house, except those specifically excluded. Many of the deaths were therefore not entirely unexpected. For instance, all deaths following operation for enlarged prostate, gastric or duodenal ulcer and gall stones are included. The cases excluded comprise out-patients; eye, ear, nose, throat, and gynaecological cases, except when operated on by a general surgeon; big accident cases; cases of cancer, intestinal obstruction, strangulated hernia, peritonitis, osteomyelitis, septicaemia, pyaemia, cellulitis, carbuncle, diabetic gangrene, myelocele, cerebral tumour, and exophthalmic goitre. Two or three deaths due to a technical error in the operation are also excluded.

The total operations in the period numbered about 16,000.

NASAL INFECTION IN CHILDREN.

AN ANALYSIS OF 85 CASES TREATED BY AUTOGENOUS VACCINE.

BY

LEONARD MACKEY, M.D., M.R.C.P.,

PHYSICIAN, QUEEN'S HOSPITAL, BIRMINGHAM.

IN response to the suggestion of a medical colleague specially interested in diseases of children, I turned up the records of all the children (85) who had been brought to consult me between 1915 and 1925, whose illnesses I attributed to nasal infections, and for whom I had prepared autogenous vaccines.

I then wrote to each child's medical attendant and asked: What was the result of the vaccine treatment? and Did the administration of the vaccine upset the child?

I received answers from all. In eighty-three cases the inoculations caused no inconvenience and the full course was administered; in one case the reactions were so severe that the vaccine was discontinued, and in one case the vaccine was stopped because the child got whooping-cough. The therapeutic effect of the treatment appears later, and is so satisfactory that some analysis of the cases cannot fail to be of some scientific and clinical interest.

The average age of the children was 8 years. The following table shows the complaint for which I was consulted, and the result as reported recently by the medical attendant.

Complaints.	Cured.	Much Improved.	Little or no Improvement.
Asthma	1	1	0
Bronchitis and asthma	5	7	0
Chronic bronchitis	11	2	2
Chronic bronchitis and nasal catarrh	12	6	1
Chronic nasal catarrh	17	11	2
Recurrent pyrexial attacks	3	0	0
Recurrent pneumonia	2	0	0
Total	51	27	5

Naturally every child was brought to me by the father or mother, whose anxiety centred either on the poorness of the child's general health, the fear that "consumption" would develop, or the inability of the child to attend school. These children for the most part had had prolonged medical treatment, had failed to benefit from a change at the sea, and the tonsils and adenoids had been removed.

When the vaccine was begun all other treatment ceased. In every case the vaccine was given every week for twelve or fourteen weeks.

The bacteriological findings were as follows:

Pneumococcus	73 cases
B. influenzae	31 "
Friedländer's bacillus	17 "
Staphylococcus aureus	11 "
M. catarrhalis	9 "
Streptococcus	*6* "
Streptococcus pyogenes	2 "
Bordet's bacillus	1 case.

From these figures it will be seen that although the pneumococcus was present in nearly all cases, in most instances one of the other germs was present also. No notice was taken and no record kept of diphtheroid bacilli, hard colonies of chromogenic diplococci, or any other germs which were regarded as unimportant.

The vaccines were usually made from primary cultures or first subcultures, sterilized by heat. Their strength varied with the ages of the children. In a child of 8 the initial dose was about five million and the final dose fifty million of each germ employed.

The cultures were made from nasal swabs on plates of blood agar and pepsinized blood influenza medium. *Never more than five minutes was allowed to elapse between the taking of the swabs and the inoculation of the media.*

In some cases sputum was available, but added nothing to the bacteriological findings from the nasal cultures. The cultures were usually so profuse as to leave no doubt as to the reality of the infection.

My own belief is that the infection in such cases lies in *one or more of the nasal sinuses*, and the results confirm the opinion, which I have held for many years and expressed in the JOURNAL on more than one occasion in the past, that not only in nasal catarrh, but also in chronic bronchitis, certain types of asthma, and some cases of unexplained pyrexia, the cause must be sought in the nasal passages. *That one should have been so fortunate as to* get satisfactory results in over 90 per cent. of cases which had defied other forms of treatment is the excuse offered for publishing these notes.

THE DIAGNOSIS OF TUBAL ABORTION AND RUPTURE.

BY

J. S. M. CONNELL, F.R.C.S.ED.,

GYNAECOLOGICAL AND OBSTETRIC OFFICER, DUDLEY ROAD HOSPITAL, BIRMINGHAM.

TEACHERS of gynaecology and obstetrics are compelled to be somewhat dogmatic when lecturing to undergraduates; and even by the bedside they have to try to impress the student's mind with a fairly definite picture of the various types of pelvic lesions with which he is expected to deal in after-life. I think most young graduates feel that whatever else they do not know, they are not going to fail to diagnose the classical case of tubal abortion or rupture. The history that one or two regular menstrual periods have been missed; the sudden onset of pain in either iliac region, with extreme tenderness and rigidity of the abdominal muscles; the slight loss per vaginam; the rapid pulse; the pallor of the patient; and the discovery of a fluctuant mass in the posterior fornix—when all these are present there is no difficulty in coming to a quick and correct diagnosis.

This picture, however, is seldom seen, and many cases have come under my care where the diagnosis has not been made or has been made very late. When the case has been diagnosed early the prognosis is very good, but becomes rapidly worse the longer the patient continues to bleed—for two reasons: first, the drainage of blood, apart from the primary risk of death by syncope, exhausts the haemopoietic tissues, and postpones the re-establishment of an efficient blood supply; secondly, the continued

presence of blood in the peritoneal cavity increases the chances of infection from the bowel, contributed to by the invariable constipation, or, more rarely, from latent infection of the adnexa. The classical picture may fail us in the following respects:

The Missed Period.—(*a*) It is frequently observed that the first two or three months of intrauterine pregnancy are associated with menstrual loss more or less normal. This may also be the case when the pregnancy is extrauterine, and hence the history of missed periods may be entirely absent. (*b*) When the periods have been perfectly regular previously, the occurrence of intraperitoneal haemorrhage before the onset of the first menses is very rare, but the abortion or rupture may occur synchronously with the expected menses, and the condition be diagnosed as dysmenorrhoea. (*c*) The patient may be lactating, with the associated amenorrhoea, and she may be very emphatic as to the impossibility of conception having taken place. The first menstrual period after lactation and amenorrhoea is frequently copious and of long duration, and on this account the extrauterine disturbance may be overlooked. (*d*) Another group is common, in which an apparently normal period has continued for several weeks with occasional attacks of abdominal pain and faintness of varying intensity. If a period or two have been missed the diagnosis is threatened abortion, until a severe paroxysm of pain leads to more careful examination, and the pelvis is found full of blood clot, with recent blood in the abdomen.

Pain.—The first attack of pain is nearly always typical. The intensity varies from the acute disabling spasm to very slight pain, but it is always definite, always sudden, and nearly always associated with a varying degree of faintness. It passes away to a great extent in a short time (an hour or two), if the patient is at rest and no further bleeding takes place. These are points of difference from all but the rarest cases of appendicitis, with which the condition is commonly confused, owing to the associated constipation and one or two attacks of vomiting. Blood is said to be highly irritating to the peritoneum, and this is so when it is first effused, but the irritation passes off, and cases are not rare in which severe attacks of pain have occurred at intervals of a week or more, the patient going about her usual avocation, and in which, at operation, very old organizing blood clot has been found in the pelvis. The site of the pain varies. Usually in either iliac region, it may originally be umbilical or even epigastric, and in three of my cases has extended later to the left shoulder, presumably owing to the blood getting up to the subdiaphragmatic region and irritating the phrenic nerve. The point of maximum tenderness is always pelvic.

Decidual Cast.—The slight loss from the vagina is so commonly mistaken for a normal period as to call for only cursory mention, and the passing of a uterine decidual cast, in about a third of the cases, is not often noted by the patient or inquired into by the doctor, but when found it gives a positive diagnosis. The loss is usually dark brown.

General Signs.

Pulse.—The rapidity of the pulse rate varies with the rapidity of the bleeding. I have seen a case with abdomen full of blood, with a pulse rate of only 90—she had been bleeding intermittently for three weeks. Severe bleeding may also cause much surgical shock, in which case the pulse rate occasionally is low, even down to 80.

Temperature.—The usually normal or subnormal temperature does not assist very much in diagnosis. Many abdominal emergencies show similar conditions, and a late case of blood in the peritoneum may have a temperature as high as 100°.

Pallor is almost always present in both early and late cases, and this sign is not given the important place it should have in the textbooks.

Local Signs.

Rigidity and Tenderness.—Rigidity and extreme tenderness of the abdomen are by no means invariably present. In more than half of my cases the abdomen was comparatively flaccid and only slightly tender, with the peritoneal cavity full of blood. These cases include early and late ones. As in the case of pain, the irritation of the effused blood apparently passes quickly, unlike that caused by acute inflammation, where the rigidity tends to increase. In my experience the absence of this sign, more than that of any other, has given rise to mistakes by general surgeons.

Fluctuation.—The fluctuant mass in the pelvis is only found in the textbooks or in late cases. Fluctuation implies some tension, and no tension is present until the irritation of the blood has led to some peritoneal adhesions of loops of bowel, to form a roof to the pelvis (the omentum does not take much part in this, as in inflammatory lesions). These adhesions are formed only after several days, and the only sign in the pelvis is tenderness, usually extreme, and usually in all the fornices—not particularly the posterior. This helps to differentiate from suppurative conditions, where the tenderness is nearly always posterior. The fluctuant mass is an intermediate stage and not often found, the common sign being an irregular doughy mass in cases of a week's standing or longer.

It seems clear, then, that the diagnosis of tubal abortion or rupture is not the easy matter we are led to expect, and in many cases can be arrived at only after detailed examination of the history and careful investigation of the physical signs.

I now put most faith in the following: The history of sudden onset, almost always while the patient is in motion—that is, going about her work; the feeling of faintness; the missed menses, if any; the pallor of the patient, and the presence of evenly distributed tenderness in the fornices.

Memoranda:

MEDICAL, SURGICAL, OBSTETRICAL.

POISONING BY OIL OF EUCALYPTUS.

As I fail to find any record in any textbook of toxic symptoms produced by eucalyptus the following case may be of interest.

On April 27th I was called to see Mr. T., and was informed by his wife that he had taken an overdose of eucalyptus oil.

The patient was cyanosed, the respirations were very shallow, the rate being about 12 a minute. He was in a condition of stupor, and could be roused but refused to speak. The pulse rate was 50 and very feeble. The pupils were contracted to pin-point and did not react to light. The reflexes were very sluggish and there was considerable loss of muscular tone. The body was cold and clammy.

Strychnine 1/60 grain was given hypodermically and 2 drachms of mustard in water by the mouth. He vomited soon after, and the vomitus smelt strongly of the essential oil. A stomach tube was passed and the stomach washed out with two quarts of water. The patient's condition improved gradually. On regaining his normal mental condition he stated that after taking about 4 drachms of oil of eucalyptus he at once felt a pain in his stomach. A feeling of nausea soon followed, but he did not vomit. His limbs began to get weak, and this was followed by giddiness. Cold sweats and rigors were also felt, as well as severe headache. He gradually became more exhausted and then lost all recollection.

VOLVULUS NEONATORUM.

I WAS extremely interested in the article by Mr. Norman M. Dott in the BRITISH MEDICAL JOURNAL of February 5th, 1927 (p. 230), and for statistical purposes should like to record a case of volvulus that occurred in my practice.

A full-term male child, weighing 7½ lb. was born on March 14th, 1927. No meconium was passed for some four hours after birth, when about two teaspoonfuls were expelled. Thirty hours after birth the child refused the breast and appeared to be in pain. The abdomen was slightly distended, but the general appearance was good. An enema (1 drachm of glycerin to an ounce of water) brought away about a dessertspoonful of meconium. Six hours later there had been no further passage of intestinal contents, and the abdomen was more distended. Rectal examination failed to locate any abnormality. The next morning, or fifty-two hours after birth, as obstruction was evidently complete, a small amount of mucus only being passed after rectal examination, operation was decided upon. The baby was extremely ill, and the father was given the option of refusing the operation, as the chance of success seemed so remote.

Under open ether the abdomen was opened, and a condition identical with that described by Mr. Dott was found. The volvulus was of the small intestine, the twist being in clockwise direction and through 360 degrees. The intestine was extremely dilated above the site of the stricture, which was marked by a transverse yellowish-white line, almost gangrenous, owing to pressure. This occlusion of the bowel was about eighteen inches below the upper end of the jejunum. The baby died some four hours after the operation.

I must congratulate Mr. Dott on his masterly description of the symptoms and probable etiology of the condition, but would like to point out one or two points of difference. *In this instance the volvulus must have been present at* birth, or more meconium would have passed. There was at no time any faecal material passed.

There was little vomiting, this being due probably to the fact that the site of obstruction was some inches down the jejunum, and not at the third part of the duodenum. The baby hiccuped and brought up a few mouthfuls of water towards the end. The abdominal distension was general, and by no means limited to the upper abdomen, this being accounted for by the same reason.

I think that all cases of volvulus neonatorum should be investigated fully, and reported so that practitioners may be more on the look out for them. In view of the fact that volvulus is such an eminently relievable condition should a diagnosis be made early enough, we should have the possibility of its occurrence always in mind, instead of dismissing it once examinations are over. I believe that had we been bold enough to operate when this baby was but forty-eight hours old, we might have saved him.

Hamilton, New Zealand. F.R.C.S.Ed.

DOUBLE TUBAL PREGNANCY.

THE following case seems of sufficient interest to warrant placing on record.

A married woman, aged 30, with one child, 16 months old, was admitted to hospital on June 19th, 1925, complaining of pain in the lower part of the abdomen, chiefly on the right side, near the middle line, about three inches above the pubes. The pulse was 80 and the temperature normal.

Menstruation had been normal until April, the first day after last period being the 23rd of that month. On May 30th she felt a sudden acute pain in the abdomen, which was followed by a gush of blood from the vagina. This flow continued for about an hour, when the pain disappeared. She had not done anything of a strenuous nature to account for these phenomena. There was no more pain until June 14th, when the same thing occurred in the afternoon. The following day, after a bath, there was another gush of blood, which soon ceased, and, on June 17th, whilst out walking, the violent pain recurred, but was unaccompanied by the usual haemorrhage. On June 19th she was sent into hospital by her medical attendant as a case of suspected tubal pregnancy.

On admission the patient did not look very ill, and pulse and temperature were normal. Marked tenderness was found at a spot about three inches above the pubes and two inches from the middle line on the right side. Vaginal examination was very difficult, as the patient was somewhat hysterical, but a lump was located to the left of the uterus. As there were no urgent symptoms the patient was put to bed and watched. The next day a thorough examination was made under a general anaesthetic.

The uterus was slightly enlarged, and Douglas's pouch was felt to be boggy. Nothing much could be made out to the right of the uterus. There was a lump about the size of a small hen's egg to the left of the uterus. Operation was carried out under open ether anaesthesia, and a ruptured tubal pregnancy was found on the right side. The tube was removed and the pelvis cleared of blood clot. The lump on the left side proved to be an unruptured tubal pregnancy, which was removed. The patient made an uneventful recovery.

Nairobi, Kenya. N. P. JEWELL, F.R.C.S.I.

HYDATIDIFORM MOLE.

THE following case seems worthy of record, both because of the response to treatment and the rarity of the condition; Madame Boivin of Paris found it in one of 20,000 cases, and Clifton Edgar found it in a series of 15,000.

A multipara, aged 35, with a previously uneventful obstetrical history began to suffer regular bleeding and slight "bearing down" pains; the uterus was enlarged to the size of a three months' pregnancy as vague as to dates, but had had amenorrhoea. All symptoms ceased under appropriate treatment.

A month later I was called urgently and found the patient in a critical condition. She was bleeding profusely, was extremely blanched, and the pulse was almost imperceptible. Some vesicles had been passed and established the diagnosis. Measures, amongst which was the injection of pituitrin, 1/2 c.cm., were used to counteract the shock. When the patient's condition warranted, the uterus was cleared by the gloved finger with due asepsis, and another dose of pituitrin, 1/2 c.cm., administered. Stypticin was subsequently given by the mouth in the recommended dosage. In four days the bleeding was reduced to a mere stain, and in seven days had entirely ceased. There have been no further symptoms. Pathological examination showed no evidence of chorion epithelioma, but the possibility of its later occurrence is not lost sight of.

The points of interest are: (1) the immediate control of the haemorrhage by stypticin, and (2) the fact that, apart from the "doughy" feel attributed to the uterus in this condition, there appears to be little on which to base a diagnosis when the cervix is undilated, as was the case when this patient was first seen.

I am indebted to Dr. L. A. Mackenzie of Bradford for permission to publish this note.

HENRY P. O'KEEFFE, M.R.C.S., L.R.C.P.
Westgate-on-Sea.

INFLAMMATORY SEALING OF THE EXTERNAL OS CAUSING DELAY IN LABOUR.

THE following case is placed on record because of the extreme rarity of the condition.

A woman, aged 42, who had had ten pregnancies, was admitted to the Birkenhead Maternity Hospital on April 1st. Her seventh, eighth, and ninth pregnancies had all ended in miscarriage, and she had been curetted after the last two of these. She had suffered for years from a chronic vaginal discharge, and latterly there had been prolapse of the uterus with rectocele and cystocele.

On admission the patient showed definite evidence of myocarditis with albuminuria.

Labour began at 6 a.m. on April 29th, and eight and a half hours later I was called to the case. The pains were then very severe and frequent, and accompanied by bulging of the perineum and extrusion of the vaginal wall through the vulva. Examination with the gloved hand revealed a smooth, tense, rounded swelling which completely filled up the cavity of the pelvis, and came well down on the pelvic floor with each pain. Through this swelling a foetal head could be felt, but not a trace of cervix or external os could be made out. The gloves were then dispensed with, and the ungloved fingers could just detect a very faint furrow about half an inch long, running in the line of the diagonal conjugate, on the surface of the swelling. This furrow was carefully deepened with the tip of the finger and finger-nail, and after considerable resistance it resolved itself into the external os, through which a bag of membranes immediately protruded. The presentation was left occipito-anterior, the patient's condition did not cause any anxiety, and about an hour and a half later a healthy child, weighing 7 lb., was born without further difficulty or intervention.

Birkenhead. RIDTON BLAIR, *M.C.*, M.B., B.Ch.

APPENDICITIS IN AN INFANT.

THE following case seems worthy of record owing to the youth of the patient, as the youngest case I can find recorded was 7 weeks old.

A baby, 12 days old, was admitted to the Bristol Royal Infirmary on January 25th, 1927, with a history of one day's swelling of the right side of the scrotum. Vomiting occurred once, and the infant did not take the breast well, but did not seem in pain, unless the scrotum was touched. The temperature was 101°, pulse 160. There was a hard swelling of the right side of the scrotum and inguinal canal, with redness of the skin over the swelling. Mr. Rendle Short operated about two hours after admission. A scrotal hernia was found, containing the caecum and a gangrenous appendix. The appendix was removed. Apart from a small faecal fistula the child made an uneventful recovery.

I am indebted to Mr. Short for permission to publish this case.

C. I. HAM, M.R.C.S., L.R.C.P.,
House-Surgeon, Bristol Royal Infirmary.

Reports of Societies.

MEDICAL ASPECTS OF HAEMATURIA.

A MEETING of the Section of Urology of the Royal Society of Medicine was held on April 28th, the President, Mr. W. GIRLING BALL, in the chair. The discussion was opened by Sir THOMAS HORDER, whose paper is published in full at page 993 of this issue of the JOURNAL.

The PRESIDENT said that Sir Thomas Horder's remarks had illustrated the desirability of collaboration between physicians and surgeons in such a field as this. Many cases which used to be called essential haematuria were now, as a result of more perfect methods of investigation, classified in other categories.

Dr. GEORGE GRAHAM thought it remarkable that in a series of cases covering five years in the medical wards there should not have been an instance of oxaluria. A case of haematuria in an elderly woman had come under his

PERINEAL PROSTATECTOMY.

At the meeting of the Section of Urology of the Royal Society of Medicine on May 26th, Mr. GIRLING BALL presiding, an address on prostatectomy was given by Professor HANS WILDBOLZ, of Berne.

Professor Wildbolz advocated the perineal operation, which, he said, was performed seldom in this country, but which was favoured by many Continental surgeons and by a school of surgery in the United States. He opposed the performance of prostatectomy as a prophylactic measure; it was never a harmless intervention, and it was only required when the patient was in real danger. He dwelt at length on the tests of renal function now generally employed before deciding upon operation, and gave the figures obtained with his patients for the blood urea test, the phenolphthalein test, and the test for determining the specific gravity of the urine by freezing. He added that no reliance should be placed upon any one kind of determination, but only upon a comparison of several. With regard to the blood urea test, a high quantity of urea certainly forbade prostatectomy, but a normal quantity was no proof of renal adequacy. Renal function would improve quickly under treatment, with intermittent or continuous drainage by catheter, and the patient would become in a few weeks fit for operation. The lecturer went on to claim certain advantages for perineal prostatectomy as against the suprapubic operation. The perineal method, in his opinion, produced far less shock. Moreover, suprapubic intervention was followed by an increase of blood urea during the first days after operation, while perineal prostatectomy hardly ever caused such an increase. Only 18 per cent. of the patients upon whom he had performed the perineal operation showed an increase in blood urea, and that only of a trifling order; while many patients showed a lowered quantity. The perineal operation did not cause nearly so much bleeding as the suprapubic, nor did it damage so seriously the tissues of the neck of the bladder. Professor Wildbolz gave a brief description of his technique, illustrated by a series of coloured drawings of the different stages of the operation, and explained wherein his own procedure differed from that of Young and others who also practised the perineal method. He drew attention especially to his complete resection of the part of the prostatic urethra which was encircled by the adenoma, also the suture between the neck of the bladder and the urethra, and the suture of the incised prostatic capsule. Little damage was caused to the tissues by his operation, and the only bleeding of any importance was stopped nearly completely by his method of sutures. Serious post-operative bleeding very rarely happened. He had seen symptoms of sepsis in only four out of three hundred operation cases, which he thought was a better record than that of the suprapubic method. His tabulated results for 300 perineal prostatectomies showed a mortality of 6.5 per cent., whereas the mortality he had had previously with the suprapubic method of operation was 15 per cent. In 227 patients recovery followed within two weeks of the operation; in 44 cases within three weeks; in 22 cases within four weeks, and in only 7 cases was the period before recovery prolonged to five weeks or more. By some mischance lesion of the rectum occurred in 7 cases out of the 300, and in 11 some incontinence persisted, not, however, of a serious character, but usually a dribble if the patient sneezed or laughed. He urged British surgeons to give perineal prostatectomy a trial.

Sir J. W. THOMSON-WALKER said that it was rather a bold thing to recommend another method in London, where all urologists were performing the suprapubic operation, not because of antipathy to any other, but because it best suited them. Professor Wildbolz had criticized the tendency to operate early, more or less as a preventive measure. Sir J. W. Thomson-Walker had been one of those surgeons who had always advocated early operation in enlarged prostate, on the contention that a large number of enlarged prostates at the present time were neglected too long. The symptom of frequency of micturition had been looked upon as a physiological condition of old age, and its true significance in relation to the prostate had been disregarded. Every old man who had frequency of micturition ought to

be examined to see if he had any residual urine. If all the cases which were known as "silent prostates" were examined the condition of enlarged prostate would be found at an earlier stage than at present. With regard to tests for renal function, urologists had seen many of these come and go, and he was interested to notice that Professor Wildbolz had again advocated a test which was much used in this country twenty years ago, showing the specific gravity of the urine by freezing. The disadvantage of this test was that it was too variable under a slight change in the condition, such as sweating or a little diarrhoea or fever. The test which most British surgeons employed was that of the urea, but no determination by itself was quite reliable. The question with all tests was how far they ought to be allowed to decide surgical action. It was pleasant to think that a figure could be obtained from the laboratory to determine whether prostatectomy should or should not be performed, but in fact this could not be forthcoming. The only use of these tests was to show that operation was attended by a greater or a less risk; they must be used as a guide, not as a bogy. Patients could not be refused prostatectomy on all occasions where the urea was low in the urine or where the kidney tests were not good. Professor Wildbolz had given certain reasons for thinking that the perineal operation was better than the suprapubic. He had said that it did not raise the blood urea. But the suprapubic operation in itself did not raise the blood urea; it was the operation of draining the bladder which did so. With care it was possible to operate with higher blood urea concentrations even than 80 mgm. in 100 c.cm. With regard to shock, he could not see that the patients upon whom suprapubic operation was performed suffered greatly. Shock was largely a question of haemorrhage, and really serious haemorrhage was now not often found after prostatectomy. Nor did he think there need be as much sepsis as Professor Wildbolz had suggested. Quite often his own patients healed with clear urine; he could not always secure this, and it required a great deal of care, but it was not impossible. The mortality figure of 15 per cent. for suprapubic prostatectomy which Professor Wildbolz had mentioned might have been correct years ago, but it was not true now. In his last 156 cases the mortality was 4.4 per cent., which was below the figure (6.5) Professor Wildbolz had given them for the perineal operation.

Mr. RALPH THOMPSON stated that he had performed 25 perineal prostatectomies. It was not a question of what was advised by one school or another, but of what should be done for a particular patient. There were a great many prostates for which perineal prostatectomy would be preferable to the other, and vice versa. In his few cases of perineal prostatectomy shock seemed to be very much reduced. He thought, however, that there was less bleeding with the suprapubic than with the perineal. With regard to malignant disease of the prostate, provided they were certain of its extent, the perineal route was the better. But there was one great disadvantage attending the perineal operation; the smaller the adenoma the greater was the likelihood of incontinence after operation, and because this was so distressing, he felt inclined, after having performed 25 such operations, to do no more perineal prostatectomies.

Mr. JOCELYN SWAN urged that reliance should be placed on a combination of tests, not on one test, of renal function. As for the perineal operation, he had reserved it for early malignant disease. Mr. PANNETT urged that the haemoglobin estimation should be made before every prostatectomy. He believed that there was less shock after the perineal operation, and certainly one had a better view of the prostatic pouch by that route. Mr. FRANK KIDD had always felt that the perineal operation was more scientific, and he thought it safer, provided always that it was done by a surgeon thoroughly conversant with the technique; otherwise it could be much more disastrous than the suprapubic in hands similarly inexpert.

Professor WILDBOLZ, in a brief reply, said that the main objection brought against the perineal method appeared to be persisting incontinence. But in fact, in his own 300 cases, he had had not a single instance of permanent incontinence, and in the eleven cases in which incontinence had continued for more than a few days it was of a trifling character and entirely disappeared within a few months.

PROPHYLAXIS OF MEASLES.

AT a meeting of the Section of Epidemiology of the Royal Society of Medicine held on May 27th, with the President, Dr. S. MONCKTON COPEMAN, F.R.S., in the chair, Dr. W. S. C. COPEMAN read a paper on the prophylaxis of measles, with a suggested scheme for dealing with epidemics.

Dr. Copeman first briefly discussed the infectivity of measles, its mortality, and the present methods of prophylaxis. He then reviewed the history of serological methods of prophylaxis and described in some detail the methods of collecting, preserving, and employing the serum of convalescent cases of measles or of adults who have had the disease in childhood. Since the early days of serum prophylaxis, he said, scientific opinion had gradually been turning from the desirability of producing a passive immunity in time of danger to that of producing an active immunity at an earlier period. One of the methods of employing serum—"sero-attenuation," preferred by Debré and others—had the double merit of being applicable during an epidemic and yet of producing active immunity. Reviewing the results published and his own experience, Dr. Copeman put forward the following conclusions:

1. That the serum or blood of persons who have, in the past, suffered from, or are convalescent from measles, has a definite prophylactic value in this disease.

2. That if it be injected in sufficient dose, during the first five or six days after injection it will produce a passive immunity which will last for some weeks; whilst if injected between the fifth and ninth day of the incubation period, a modified form of the disease will develop, which in turn leads to the establishment of an active immunity which some observers consider to be permanent. That if it be injected later than this, no benefit will result.

3. That in the absence of certain contraindications, which have been mentioned, it is better to allow an attenuated form of the disease to develop ("sero-attenuation") than to rely on renewing the patients' passive immunity in time of danger by means of serum.

4. The use of convalescent serum in this latter way ("sero-prevention") should be limited, normally, to children under 3 years of age, since these supply 70 per cent. of the measles mortality. In this way the disease may be warded off until the child is of an age when it is no longer so dangerous. It is also indicated in the case of children suffering with tuberculosis, rickets, diphtheria, whooping-cough, and in feeble children, in very cold weather, and in institutions.

5. The prophylactic dose of serum has to be increased in direct ratio to the time of exposure to the disease.

Dr. Copeman then outlined his suggested scheme for dealing with measles epidemics, explaining that this was based on the creation of a centre for the distribution of prophylactic serum, and that it was a potpourri of the writings and ideas of many workers, notably of Debré and Godfrey. Following a recommendation of the Academy of Medicine of Paris in 1925 two centres were established for the collection and storage of serum from cases of measles and whooping-cough. At the centre to which Dr. Copeman was attached for a time 10 litres of serum, or 2,000 protective doses, were collected in the first five months, and this was sufficient for all needs. The aim at present, in England, was to prevent every case of measles, and the measure of success may be judged by the fact that about 90 per cent. of adults had suffered with the disease. In the light of present-day epidemiological knowledge, it appeared to be a policy of doubtful wisdom to endeavour to do so, unless adequate artificial immunization were insisted upon, since sooner or later, if we were successful, the infection would return, and, finding virgin soil, the tragedy of the Faroe or the Fiji islands would be repeated, on an even larger scale. P. L. Marie's terse statement, "le but n'est pas tant de faire disparaître la maladie de la face du monde, que de reculer son apparition jusqu'à un âge où les risques qu'elle fait courir deviennent très minimes," summed up the outlook towards the disease which should become general in this country. We should endeavour, by means

ent organization, with clear-cut aims and methods, rol the disease, rather than to stamp it out. Since cent. of all deaths from measles occurred under of 3 years, it was during these fatal first three hat we must eliminate the disease; postponing it, ssary, until the child was over this age and there- ore able to combat it. Few healthy children over s died of measles. It had been well said that attacked without distinction, but killed with dis- tion. If we could accomplish this, a great step l would have been taken by reducing the mortality, the morbidity, of measles. The methods by which d become possible to achieve this aim were twofold. a skeleton corps of trained public health workers, ould have the power to call upon less specifically l workers in allied departments, such as welfare , since the need would be for a large body of workers short time. Secondly, a knowledge of the where- of the children under 3 years whom it was desired tect. This system would obviously be easier of tion in large towns than in smaller places, and measles appeared to be more fatal in these areas, from the case morbidity, this seemed to some extent ision on the part of Providence. Compulsory notifi- would have to be instituted.

Copeman suggested that a serum-collecting station, sing a small laboratory and waiting room, and pre- attached to some institution where measles cases vailable, should form the centre of every unit of the ; a unit would in most cases comprise a large town, ie medical officer of health would be the central ity for the unit. The personnel of the centre would he "skeleton corps" of trained men who would, in f epidemic, take control of it under the supervision medical officer of health. Between epidemics they collect a store of both adult and convalescent serum ortunity arose, and work on the following lines:

educate the parents of small children in the belief that ics could roughly be predicted; thereby preparing the for a future campaign.

educate parents in the belief that measles in children three was dangerous, and the younger the child the more ous the attack, and that it was dangerous at any age if ld were weakly. They must beware of saying that "measles erous" without specifying "under three," since the public hat in older children it was not particularly dangerous.

make it known that serum was available for these cases, at its amount was limited, and that donors (voluntary or sated) were continually required to "save the children." ersonnel could visit the scene of epidemics and deal with n the spot, on application from general practitioners. They ot limit their activities to measles, although this would be le in the initial stages.

chief available channels for this propaganda were ewspapers, private doctors, occasional public lectures re or less popular lines, and notices, such as were dis- l in some boroughs. In addition, the staff concerned l have at their disposal a card index, containing the s and addresses of all children under 3 years of age ir area. This could be managed easily if duplicated of birth certificates reaching the medical officer of were sent to them. This would probably account ore than 90 per cent. of the true number of births. ames of the children could be indexed by streets or cts, and all notifications and child death certificates l be sent through this department. The names of on their index thus known to have died or had measles l be removed. The index would be revised every year moving all those cards relating to children more than rs of age.

e paper was followed by a brisk discussion, which was d by Sir GEORGE BUCHANAN, who outlined what were, s opinion, the chief difficulties in the way of Dr. AN's scheme. He thought, however, that it should be on a small scale to begin with, and that this would be teresting and valuable experiment. He was followed ir WILLIAM HAMER, Dr. J. D. ROLLESTON, Dr. J. AM FORBES, Dr. O'BRIEN, Fleet Surgeon HOME, and S, all of whom expressed interest in the paper and the osed scheme, and hoped that it might be possible to try this country.

ANTE-NATAL PREVENTION OF DIFFICULT LABOUR.

AT a meeting of the Forfarshire Medical Association on April 21st, at University College, Dundee, the President, Dr. R. C. BUIST, in the chair, Professor J. A. KYNOCH opened a discussion on ante-natal measures for the avoidance of difficult labour.

Professor Kynoch said the chief aims of supervision of pregnancy were, in the early months, to preserve the pregnancy, and in the last three months to foresee and prevent difficulties and complications in labour. To be of most value, ante-natal supervision must begin early in pregnancy. In malpositions a transverse position could always be corrected by external version even up to the commencement of labour. With a breech presentation in a primiparous patient an attempt at conversion should always be made by external version, but not until the last week or two, since, if performed earlier, there was apt to be a return to the old position. In occipito-posterior positions he advocated the use of pads and binders, as recommended by Dr. R. C. Buist. Another cause of difficulty in labour was undue prolongation of pregnancy. If the patient could give accurate dates, and the pregnancy lasted fourteen days beyond the expected time, then induction of labour should not be delayed. In connexion with pelvic deformity as a cause of difficult labour, pelvimetry during pregnancy was of great importance. It was well, however, to remember Barbour's axiom: "The child's head is the best pelvimeter." Failure of the head to enter the brim in the last weeks of pregnancy in a primiparous patient must always be taken as a warning of possible trouble. X-ray examination was occasionally of service in ante-natal diagnosis, especially in breech and transverse presentations and in multiple pregnancy. It was also of value in the diagnosis of some of the rarer varieties of pelvic contraction. In conclusion Professor Kynoch remarked that modern life did not predispose to an easy labour. He added that the excessive craze for athletics might favour in young women the occurrence of the male type of pelvis with its obstetrical disadvantages.

Mr. A. E. CHISHOLM emphasized the importance of abdominal examination, and advocated measurement of the fundus in estimating the time of labour. In locating the foetal heart sounds the Pinard stethoscope was of the greatest value.

Dr. GEORGE WHYTE was in favour of combined abdominal and vaginal examination. One cause of difficulty was an unusually large child with labour occurring at the right time; here also induction might be indicated.

Dr. JAMES STALKER, while agreeing that abdominal examination was preferable, found that he had to rely very much on vaginal. The most difficult position to diagnose was the occipito-posterior. For listening to the heart sounds, he preferred the stethoscope he used every day.

Dr. GEORGE MILLER also mentioned the difficulty in diagnosing occipito-posterior positions. He agreed that the Pinard stethoscope was of great help.

Dr. MARGARET FAIRLIE thought that in a breech case version should be performed three or four weeks before labour, and pads and bandages applied to maintain the new position. In cases of difficult labour she considered it essential to have an anaesthetist.

Dr. J. M. MORGAN could not agree that there was any special tendency to difficulty in labour in the athletic type. On the contrary he considered that owing to more hygienic fashions in dress, first confinements were becoming easy and rapid in an increasing number of cases.

Dr. F. M. SKAE asked how a hydrocephalic head could be diagnosed with any certainty, especially without vaginal examination.

The PRESIDENT said that difficulties in labour arose in two or three simple ways. There was first the position of the child, requiring chiefly abdominal examination for the diagnosis, and external version and the method of the pad and binder for treatment. Secondly, there was disproportion in size, when induction of labour had to be considered. He described a method of tapping the amnion above the foetal head. The third factor was the power of the patient, which, at times, quinine usefully reinforced.

Reviews.

VACCINATION: HISTORY AND SOCIOLOGY.

THE vaccination controversy, which began after Edward Jenner's inoculation of James Phipps with cow-pox in 1796, is the subject of a work of modest dimensions by Mr. BERNHARD J. STERN,[1] Instructor of Sociology at Columbia University. His interest in the subject is historical and social rather than medical, and he moves among the antipathies of the contending parties with serene detachment.

The first outspoken opponents of Jenner's vaccination against small-pox were [illegible] Continent, and Sims and Moseley in [illegible] died within the year, and Sims, though he suspended judgement at first, afterwards became a zealous advocate, but Moseley's hostility was unwavering. "Who knows," he said, "but that the human character may undergo strange mutations from quadrupedian sympathy and that some modern Pasiphaë may rival the fables of old?" Merry of Bath, a practitioner of variolation, held like views. He stated that vaccination was "comparable with incest, introducing into the human body a disease of bestial origin similar to syphilis." The unbridled style was not peculiar to the opposition. Jenner himself was most resentful of criticism, and one of his defenders described those who queried the merits of the cow-pox inoculation as "reptiles that plant themselves in the high road of improvement and try to hiss back all who would advance." When Goldson in 1804 proposed that experiments should be instituted to determine whether there was not a limited period to the preservative power of vaccination, Ring of the Royal Jennerian Society, then in its second year, wrote that the society, fully convinced of the absurdity of the hypothesis, did not think it necessary to comply with his request. Yet Goldson's idea was correct. Through such exchanges and in other ways some popular feeling was aroused, and in 1808 the Royal Jennerian Society had to close its doors.

Notwithstanding opposition in various quarters, however, the vogue of vaccination grew. The Jennerian Society was succeeded in 1809 by the National Vaccine Institution, and the Vaccination Act of 1840 provided for gratuitous vaccination. But with the passing of the Vaccination Act of 1853, which made vaccination compulsory, the conflict took on new vigour. Hitherto mainly an affair of experts contending on points of medical practice, it transferred itself to a wider field. It was a question now for the people of England. The cause was the sacred cause of freedom. The opposition availed themselves of the weapons thus supplied. They obtained religious support. They founded the Anti-compulsory Vaccination League. Evasion of the Act, despite prosecutions, became persistent, and in some areas the measure was a nullity. Great protagonists came down into the arena. John Bright and Herbert Spencer were opposed to compulsion. A. R. Wallace said that liberty was greater than science, and that vaccination was a terrible blunder. The plea of sanitation as an alternative to vaccination enlisted the active support of thousands. The Leicester experiment was undertaken. The Royal Commission sat and reported, and the Vaccination Act of 1898 recognized the position of the conscientious objector, who in 1907 was awarded the further concession of the statutory declaration.

Such, in summary, was the course of the vaccination controversy in England as surveyed by Mr. Stern. Analysing its motives, he comments on the intolerance of Jenner and his allies. It must be recalled, however, that they were intensely in earnest. They had found the preservative for the scourge of their times. Mr. Stern thinks that the early opponents were insincere, desiring to keep variolation alive on interested grounds. Some perhaps were disingenuous, but others were doubtless honest, if self-conceited, brethren, "giving liking to nothing but what is framed by themselves." Medicine, as well as the Church, has witnessed such, both then and since. Both sides used strong language, and with expressions like "incest" and "reptiles" flying, it is easy to see how the dispute thus early assumed an intemperate character which to some extent set the tone of its later phases. The agitation which followed the compulsory Act of 1853 was inspired by a new motive, quite genuine on the part of many. They were concerned for liberty. The Englishman's right, as Dr. Gregory had put it, of going to the devil in his own way, appeared to be at stake. But the antivaccinationists, pursuing their ends, diligently fanned the popular prejudice and imported into the campaign a good deal of the acrimony which had made itself apparent earlier in the movement.

The same kind of opposition as was met with in England was experienced in America and European countries. Vaccination throughout has suffered from the fact that it was a prodigy at the time of its birth. Had it seen the light first a hundred years later, in a world which was better informed, it would probably have aroused as little antagonism as diphtheria antitoxin.

THE EGO.

THE nature of that elusive entity—the ego—has been the subject of much speculation throughout the ages, and many are the egos which have been conceived by the minds of philosophers. Thus there is the empirical or objective ego of the academic psychologist. This is just an object like other objects which becomes differentiated from the external world by the individual in the course of his mental development. For William James "the empirical self of each of us is all that he is tempted to call by the name of *me*." When this *me* is introspectively studied it is found to have fairly constant and somewhat uninspiring constituents: a visual perception or idea of the body, organic and kinaesthetic sensations, and the verbal ideas of "I" and "my." Titchener, who writes with authority, informs us that the usual pictorial image of the self consists in a picture of the body in some unaccustomed dress or posture. Certainly the idea we have of ourselves is very different from that which other people have of us. Then there is the intangible subjective or "transcendental" ego of Kant. This has no positive attributes, cannot be directly known by introspection, and from it nothing can be deduced. It tells us, in contrast to the empirical ego, "not how we appear, not how we inwardly are, but only *that* we are."

In contrast with this nebulous and unknowable ego is the personified unconscious "super-ego" which FREUD has discovered in the course of his psycho-analytic investigations. The functions, attributes, activities, origin, development, and location in the mind of this new entity are described in a monograph entitled *The Ego and the Id*.[2]

This super-ego or ego-ideal may be said to be already known to us in a measure as it would appear more or less to correspond to the "still small voice" of conscience. It is the hidden force, so Freud believes, which dominates and restricts the actions of the conscious personality. It is the "Thou shalt" of the moral law; the categorical imperative of Kant—"An imperative, which, irrespective of every ulterior end or aim, commands categorically." Freud states that the super-ego develops from the father-complex; it is the representative of our relation to our parents. When we were young we admired and feared them, and later we took them into ourselves, and they became unconsciously part of our own personality. Further, though this super-ego is amenable to later influences, it preserves throughout life the character given to it by its derivation from the father-complex—namely, the capacity to stand apart from the ego and rule it. It is a relic of the former weakness and dependence of the ego, and the mature ego remains subject to its domination throughout life. As the child was once compelled to obey its parents, so the ego submits to the categorical imperative pronounced by its super-ego. It is this unconscious part of our ego which Freud considers is responsible for the higher moral, spiritual side of our natures, and which is also the repressing force which inhibits the "id" (the primitive,

[2] *The Ego and the Id.* By Sigm. Freud, M.D., LL.D. Authorized translation by Joan Riviere. The International Psycho-Analytical Library, No. 12. London: L. and V. Woolf, the Hogarth Press. 1927. (Roy. 8vo, pp. 88; 1 figure. 6s. net.)

non-moral unconscious) from invading the psychic life and controlling the behaviour. Briefly, it appears to be Freud's much criticized and hitherto undefined *censor* whose function it is to protect the conscious mind (both waking and sleeping) from the encroachments of the primitive life impulses.

A different view as to the nature of the ego or "kernel of the personality" is expressed by Dr. William Brown in his recent book on *Mind and Personality*.[3] The aim of this volume is to consider the general problem of personality from various points of view, and to attempt to adjust them to one another. With this end in view he discusses his thesis from the standpoints of biology and physiology, of the various schools of psychology, psychopathology, logic, ethics, and metaphysics, and finally from that of the theory of religious experience. As a result of these studies he arrives at the conclusion that, in addition to the self or mind which the psychologist deals with, there is a something which expresses itself in the realization of the absolute values—truth, beauty, and goodness—and which constitutes the soul or true ego of man. Briefly, he takes the view with which the Dean of St. Paul's has made us familiar, that the world of values, which forms the content of idealistic thought and aspiration, is the real world; and that in this world we find our own immortality. Leaving aside any question as to the validity or otherwise of the mystical doctrine to which Dr. Brown gives his adherence, there is something to be said for the view that appreciation of values is part of the innate equipment mankind. Further, goodness, as distinct from conventional morality, is a quality which often appears to emerge ite naturally in the course of mental development, and opendently of impositions from without or within. There ld seem to be something pathological in the personified science or super-ego which Freud regards as responsible the development of spiritual qualities in mankind, gh we do not question the importance of parental ence in the formation of character. What are termed al relations appear to be a natural development of the rs of life in a social medium; they represent the onal aspects of the mutual adjustment between the nts of the social aggregate which are essential for tinuance and development. It may be pointed out, hat animals often exhibit behaviour to which the ethical" may be suitably applied. In such cases the ess" is clearly natural and unconscious, and there ecessity to assume the existence of a super-ego to for its occurrence.

REATMENT OF VENEREAL DISEASE.

ears numerous works—good, bad, and indifferent peared on the diagnosis and treatment of venereal The recognition of the importance of venereal a factor in national health and the establishee clinics throughout the country have stimulated t of the profession in what was once a neglected nedicine. Dr. David Lees's recently published is subject has the advantage of being eminently n its outlook. The author is lecturer in eases to the University of Edinburgh as well in charge of the venereal department in the ary and the Royal Maternity Hospital. He e at his disposal an enormous amount of rial, as well as a special knowledge of the ersity students and post-graduates. His book, utcome of his work at Edinburgh, is intended of students and practitioners, and has no be a work of reference. His sense of what ould be taught has led him to stress the f his subject, and the lesson that he inculothers is that the disappearance of the ptoms of the disease does not necessarily mean the cure of either syphilis or gonorrhœa. Unlike many other authors who have dealt at length with the subject of syphilis and have scamped the more difficult one of gonorrhœa, Dr. David Lees has devoted a large part of his book to the latter subject. It is only the enthusiast who is able to avoid striking a pessimistic note when dealing with the treatment of gonorrhœa, and, fortunately, the author is an enthusiast. Our failure to achieve any substantial advancement in the treatment of this disease during the last ten years has not damped his ardour, and there is no reputable remedy to which he has not given a trial. After dealing with the various antiseptics which may be used for irrigation, and with such local methods of treatment as dilatation and cauterization, he discusses vaccines. In his opinion an autogenous vaccine prepared from the patient's own organisms is not in general so effective as a polyvalent detoxicated vaccine. The explanation, he considers, is to be found in the fact that the infecting organism does not, as a rule, serve as a good antigen, but that with the use of a polyvalent vaccine containing numerous strains there is a greater probability of obtaining some of better antigenic value. The ideal would appear to be the combination of a polyvalent detoxicated gonococcal vaccine with an autogenous vaccine of the patient's infecting organism. By this combination is obtained polyvalency and strong antigenic properties, and at the same time absolute specificity. The treatment that he advocates in both male and female may be summed up as follows: local antiseptic therapy by irrigation, instrumental treatment to establish good drainage, prostatic and vesicular massage to open up all foci of infection and provide them with a good blood supply, and, finally, the use of a vaccine as a means of increasing the patient's resistance to the infecting organism. A useful feature of the book is the addition of formulae likely to be of service in the treatment of venereal disease. The work is illustrated by photographs obtained from the author's own cases; they have been well chosen and, without being unnecessarily numerous, are such as to serve their purpose of rendering the text more easily understood. We can confidently recommend *Diagnosis and Treatment of Venereal Diseases* to all students and practitioners wishing to bring up to date their knowledge of venereal disease. It should acquire a popularity as great as that enjoyed by Colonel Harrison's book on the same subject.

Treatment of Venereal Disease in General Practice,[4] by E. T. Burke, has been written for practitioners undertaking a certain amount of treatment of venereal disease. The author in his preface complains that medical bookshops are lumbered with colourless tomes on venereal disease, stamped with the hall-mark of mediocrity and giving the impression that the treatment of venereal disease is bristling with difficulties that can only be overcome by a highly trained specialist; as the result, the practitioner throws up the sponge and salves his conscience by doling out bottles of ineffectual medicine. Though we have here yet another work on the subject, the most hostile critic would find it impossible to apply to it the word "colourless" or to suggest that it is merely a rehash of previously published manuals. From the start emphasis is laid on treatment, and instead of general and somewhat vague therapeutic directions precise instructions are given. In a chapter labelled "Obiter dicta Syphilitica," the author expresses his opinions with refreshing vigour. "To treat the cutaneous manifestations of syphilis as if the disease were merely one affecting the skin, is as sane as painting the leopard's spots yellow and then introducing him into the home as a domestic pet." In discussing the treatment of gonorrhœa, the author speaks forcibly of the use of vaccines. "It is no more justifiable to omit vaccines in the treatment of gonorrhœa than to omit antitoxins in diphtheria." And again: "The chief causes of complicated and chronic gonorrhœa are over-treatment, too early and too frequent prostatic massage, the use of small

hand syringes, and the omission of vaccines." Whether we agree or disagree with some of the statements, it is refreshing to find a book which reflects so truly the ideas of the author, and borrows so little from other manuals.

EPIDEMIC DISEASES OF THE CENTRAL NERVOUS SYSTEM.

DR. ARTHUR SALUSBURY MACNALTY has now produced in expanded form his Milroy Lectures delivered in 1925 on the *Epidemic Diseases of the Central Nervous System*.[6] The work is published in an attractive volume of some 200 pages by Messrs. Faber and Gwyer (the Scientific Press). Dr. MacNalty has earned the right, by his well known personal researches as a medical officer of the Ministry of Health, to review with authority the facts which are known, and the hypotheses which exist, with regard to the epidemic manifestations of the three diseases with which the lectures dealt—namely, cerebro-spinal fever, acute poliomyelitis and polio-encephalitis, and encephalitis lethargica.

The earlier chapters are concerned with the various theories which have been advanced to explain the epidemicity of these diseases in general. Dr. MacNalty accepts the view that epidemics have been favoured by the increased opportunities for infection resulting from modern transport facilities, as was seen especially during the war, but is of opinion that this can only be a partial explanation. He is not impressed by the evidence in favour of epidemic cycles in poliomyelitis and encephalitis lethargica, though that as to periodical cycles is well established in the case of cerebro-spinal fever. Neither is he as yet prepared to accept the view that these three diseases are related in some way to pandemics of influenza, and considers it wise still to regard them as separate diseases not arising from some common condition or "epidemic constitution." He is inclined to favour the belief that modern conditions of stress have increased the susceptibility of the nervous system to infection. An interesting chapter on epidemic nervous diseases in animals concludes with the opinion that insufficient evidence exists to associate such diseases with the increased incidence in man of the three diseases under consideration. The history of these diseases is then considered and the evidence reviewed which has gradually accumulated in favour of their epidemic nature. In respect of cerebro-spinal fever and poliomyelitis it is indisputable and well recognized, and especially the importance of carriers, but it is necessarily more scanty as regards encephalitis lethargica. The summary of the evidences of personal infection which the author provides is therefore of special interest.

Succeeding chapters deal with the epidemiological features of each disease in detail, and with the practical principles which arise therefrom in respect of the prevention and control of epidemics. The author's final appeal is for a closer study of the little-explored subject of personal variation in susceptibility to infection, a subject in which the clinician and bacteriologist may well collaborate with the epidemiologist.

SUPERFICIAL RADIUM THERAPY.

THE scope of radium therapy has been widening so rapidly during recent years that a concise and up-to-date account of this line of treatment is desirable, if only as a milestone. Mr. A. E. HAYWARD PINCH, medical superintendent of the Radium Institute, London, has therefore set himself to review the valuable clinical material which has been collected in the course of the sixteen years' existence of that institution in order to define the curative possibilities of this remedy. In his book *Superficial Radium Therapy*[7] he deals with the treatment of growths or lesions which do not extend more than one centimetre below the surface of the body, the apparatus used being unscreened or so lightly screened as to permit the passage of a preponderant beta radiation. Mr. Pinch proposes to issue at a later date a companion volume on deep radium therapy.

In his present book he devotes the first three chapters to the methods he employs, and to the histology of the skin and its appendages. He then considers hypertrophies, new growths, and congenital affections of the epidermis; neoplasms of the corium; angiomata; and inflammatory conditions of the skin. He devotes special chapters to tuberculosis, affections of the hair and mucous membranes, actinomycosis, and pruritus. A prominent feature of the book is a series of forty-eight full-page photographs illustrating the clinical conditions before and after radium treatment. The great mass of information is very skilfully condensed, the arrangement is good, and the various practical points are clearly detailed. Careful revision has removed superfluous descriptions, and the requirements of both experts and novices in radium therapy have been kept in view. The sound, scientific treatment of the subject is refreshing in these days of rather noisy advocacy of therapeutic procedures, and the claims he makes cannot be branded as excessive. The book can be cordially commended to general practitioners, by whom it may be obtained free on application to the secretary of the Radium Institute, 16, Riding House Street, Portland Place, W.1.

TREATMENT OF DIABETES MELLITUS.

THE earlier editions of Dr. OTTO LEYTON'S small guide to the *Treatment of Diabetes Mellitus*[8] appeared before the use of insulin had revolutionized our methods of dealing with that disease. The fourth edition has therefore undergone considerable modifications, and the employment of insulin is discussed. Dr. Leyton considers the treatment of diabetes under three headings: (1) by diet alone; (2) by diet with insulin; (3) by other preparations with or without insulin. Of the third method he says that none of the drugs other than insulin which have so far been tried has proved satisfactory. Some of them lead to a diminution of sugar in the urine, but none of them increases the power of the individual to burn or store carbohydrate, and therefore the benefit derived is apparent rather than real. Moreover, he insists that insulin is only efficacious when administered by hypodermic, intramuscular, or intravenous injection. The truth and importance of these remarks deserve the widest acceptance and reiteration. Nothing can be more distressing than to meet with patients suffering from diabetes mellitus who are led to hope that the mere decrease of glycosuria is an evidence of return to health.

Leyton's advice as to the selection of patients suitable for treatment by diet alone is excellent, and in nothing is his good judgement better displayed than in his criticism of attempts to standardize diet according to the height and weight of the patient. "The energy in the diet of the patient should be," he says, "the least which will allow the patient to maintain his weight and to carry on his work." If the patient cannot tolerate such a diet without a rise of blood sugar above 0.15 per cent., treatment with insulin becomes imperative.

His plan for the use of insulin with diet is simply described and based on sound foundations. He starts with an adequate maintenance diet and finds the dose of insulin required to enable it to be utilized. He does not make the patient fast, nor approach the adequate maintenance diet by gradual steps. He holds that his plan gives the pancreas the necessary rest and nourishment to allow it to regenerate. His experience of the degree of recovery possible even in severe cases may be received with some scepticism by those who have limited their patients' diets and allowed the barest minimum of insulin. His section on prognosis may seem to some readers unduly sanguine, but he is not alone in his experience that if the disease is of comparatively recent origin, and the blood sugar is kept below 0.15 per cent., then with adequate diet and adequate insulin the patient will, as time passes, require less and less insulin. Dr. Leyton instructs his patients whenever possible to estimate their own blood sugar, and apparently he is fortunate enough to find many patients sufficiently intelligent to do this. There can be little doubt that the prognosis in patients of this degree of intelligence

[6] *Epidemic Diseases of the Central Nervous System.* By Arthur Salusbury MacNalty, M.A., M.D.Oxon., M.R.C.P. London: Faber and Gwyer, Ltd. (Demy 8vo, pp. xiii + 194. 12s. 6d. net.)

[7] *Superficial Radium Therapy.* By A. E. Hayward Pinch, F.R.C.S. London: The Radium Institute. 1927. (Demy 8vo, pp. xv + 64; 50 plates.)

[8] *Treatment of Diabetes Mellitus.* By O. Leyton, M.D., D.Sc., F.R.C.P. Fourth edition. London: Adlard and Son, Ltd. 1927. (Cr. 8vo, pp. iii + 88. 6s. net.)

describes a method of treatment without blood sugar estimation which may prove useful to practitioners in country districts where laboratory facilities are lacking. Dr. Leyton has devoted one section to the cases where insulin fails, and he uses the expression, "When one is quite satisfied that insulin fails to act." But the question is: Should one ever be "quite satisfied" on this point? Professor Marcel Labbé (JOURNAL, March 19th, 1927, p. 530) has brought forward cogent reasons that should make us hesitate. We feel fairly sure from other parts of his book that Dr. Leyton takes more than a little satisfying too. His book is a thoughtful and practical guide well suited for the busy doctor.

Dr. WILDER, who is in charge of the section on nutrition the medical division of the Mayo Clinic, has just brought t a further impression of the third edition of his *Primer Diabetic Patients*.[9] The book is not intended as a guide self-treatment, but to give the patient sufficient informato enable the physician's directions to be carried out understanding and willing co-operation. In order that otony in diet may be avoided the patient is shown how range his diet according to a given prescription based rams of carbohydrate, protein, and fat. Numerous ry recipes are included, which will be found really . There is no disease in which it is so essential for atient to be well instructed. Only experience can how far that instruction may wisely go. The fact Dr. Wilder's book has run through three editions suggests that he has been successful in reaching, t overstepping, the limits of useful information for e patients.

NOTES ON BOOKS.

little difficult to understand why a barrister and man should spend much time in translating from n a verbose book such as *Woman*,[10] by Dr. BERNHARD , a gynaecologist of Vienna. Yet Dr. NORMAN d Mr. E. S. JERDAN have apparently thought it le to place it within the reach of those who cannot an. The preface to the translation concludes with nt that it "is intended primarily for the medical, educational professions"; the most optimistic foreresume that its circulation will be very large. ife clear what the motive can be for bringing such a medical practitioners. It does not contain any aterial that has not already been dealt with in ations and English books. Citations of sexual ther countries, which are made at some length, id to be of value to the British practitioner, interested in comparative and historical surveys t, in which case he would obtain information ealing with these matters. The book is lengthy t, and contains the author's own opinion on ts. It is arranged in five parts: the first deals le body and its functions, the second with the oman, the third with the sexual life of woman, h the erotic life of woman, and the last with rriage. There is an appendix on prostitution from Austrian observations and statistics.

h Veterinary Series, under the general editor- C. Bradley, is now well known as providing and reliable textbooks for veterinary students the best in use among medical students— ddition to this series, by R. G. LINTON, on *and Veterinary Dietetics*,[11] is no exception t the subject is important is a commonplace, knowledge of animal nutrition is responsible more disease among animals than any other ually well known. It is, therefore, the more adequate book on the subject has previously untry. The present volume, however, more or the delay. Mr. Linton considers nutri-

and Veterinary Dietetics. By R. G. Linton, Veterinary Series. Edinburgh: W. Green and vo, pp. xi + 393; 12 figures, 4 plates. 21s. net.)

tion in its general aspects, discusses the various foodstuffs available, their nutritive value, and their preparation and storage, and gives detailed instructions for the feeding of farm animals, dogs, and poultry. It is written in an easily understandable manner, and ought to find its way into the hands of everyone interested in the care of animals. We would suggest that in the next edition there should be included instructions for the feeding of goats, cats, and the various laboratory animals. Even with this omission, however, this book has a value far beyond the limits of the veterinary profession, and we congratulate its writer on a very desirable contribution to the science of animal nutrition and dietetics.

Dr. PIERRE KAHN'S *Guide de Psychiatrie*[12] is not a comprehensive treatise on mental disorders, but, as its title indicates, a guide to the understanding of these maladies; and it is everything a guide should be; eminently practical, free from unnecessary technical phraseology, and unburdened with metaphysical speculation, it presents an accurate picture of the various psychoses, especially in their bearing on the many problems that confront the practitioner in their diagnosis and treatment. It may also be read with profit as an introduction to the larger textbooks on the subject of mental disease. The chapter on the method of examining a mental case is particularly good, and the section devoted to the diagnosis and treatment of toxic confusional states is of great practical utility. The author's account of schizophrenia and its occasional development in the course of a toxic confusional insanity is both interesting and helpful. The chapters dealing with certification in France and with the medico-legal implications of insanity, good as they are, will necessarily make only a limited appeal to British practitioners. A useful vocabulary of technical terms completes the work. Dr. Kahn is to be congratulated on the production of so excellent a guide.

The forty-sixth volume of the *Transactions of the Ophthalmological Society of the United Kingdom*[13] contains the proceedings during the past year of this society and also of the Midland and North of England Ophthalmological Societies, and of the Oxford Ophthalmological Congress in 1926. The various papers are well illustrated, and the book is a useful record of recent progress made in this subject in Great Britain.

THE CRISIS IN CHINA.

A MEDICAL REPORT.

FURTHER details have now been received about the serious occurrences in Southern China, indicated in the cable sent from Shanghai to the headquarters of the British Medical Association, which was reproduced in our issue of April 9th (p. 680). The signatories of the cable, numbering thirty-two, include the most prominent medical practitioners in the disturbed areas, and the information now supplied by Drs. E. L. Marsh, J. L. Maxwell, and Gordon Thompson illustrates the grave nature of the threat to Shanghai. Dr. Marsh, who is vice-president of the Shanghai Medical Society, has replied as follows to the cable of sympathy sent by the Council of the British Medical Association at its meeting on April 7th: "On behalf of the British medical profession in Shanghai I wish to express our sincere thanks to you for this very kind and helpful message. We greatly appreciate the Council's sympathetic and powerful interest at this time. The prompt action of the Council in response to our request is noted and appreciated with much satisfaction. Please convey to the Council our most grateful thanks. Before I conclude, I must refer to our Government's splendid effort in sending troops to defend us. This generous help has given not only our own nationals, but all others in Shanghai, a special sense of security and protection, which is constantly receiving heartfelt acknowledgement through telegrams, public press, and platform."

Attacks on Hospitals and Medical Colleges.

The following record of destructive assaults on various hospitals and medical colleges illustrates the blind fury of the Chinese nationals against philanthropic institutions

which, supported by foreign generosity, have for many years ministered gratuitously to the bodily needs of the local inhabitants, and have established educational centres where Chinese students may be trained in the prevention and cure of disease. Dr. Maxwell states that, while the Northern troops have been often justly accused of looting, he knows of no damage having been done by any retreating army, all the outrages being attributable to Southern troops or their civilian sympathizers. From nearly all areas come reports of unprovoked outrages on the foreign and loyal Chinese staffs; the foreign doctor in peril of death, or pleading with howling mobs for leave to continue the hospital activities; looting and destruction of property; broken promises to hospital authorities and revengeful cruelty to the innocent and unprotected; confiscation and robbery under arms; and the infliction of needless misery upon thousands of suffering patients.

Canton.—The first institution to suffer was the Canton Hospital, which was closed in March, 1926, in circumstances described in our issue of April 24th, 1926 (p. 753). This hospital—the oldest in China—had existed for ninety years, and in it had been treated more than two million Chinese patients. It was administered by a local missionary union, and Dr. J. O. Thompson, its medical superintendent, is a Canadian. Dr. Sun Yat-Sen was at one time a student there, and retained deep interest in it until his death. The local labour union, after issuing an absurd ultimatum, cut off the supplies of food, light, and heat, with the connivance of the Canton Government, so that seriously ill patients had to be turned out into the street. The hospital is still closed, and the buildings are falling to pieces, no repairs of any kind being permitted. The Kung-Yee medical school, which was one of the finest of the Chinese institutions, and was governed by a board of Chinese trustees, with foreign assistance, was the next to suffer. It was confiscated by the local government, and is now empty and heavily in debt. The J. G. Kerr Hospital for the Insane, which is controlled by the American Presbyterian Mission, was recently compelled to close; the nature of the interference with this institution has already been described in our issues of February 26th (p. 392) and March 26th (p. 581). The local government forcibly entered part of the empty building, and is now using it for asylum purposes. This is a particularly senseless outrage, as the hospital was the only properly organized one of its size for the insane in the whole of China, and accommodated some 800 patients when in proper working order.

Wuchow.—The work of the hospital of the American Baptists here was stopped by local malcontents, despite official promises to the contrary. The institution was sealed officially with Chinese and American seals, but these were shortly afterwards broken by the military authorities, who used the buildings for a time for their own purposes. More recently the local government compelled the evacuation of the hospital, and it was handed back to the Mission, which reopened it.

Fatshan.—The English Wesleyan Mission Hospital here was seized shortly after the closure of the Canton Hospital, and for a short time was used by the troops for barracks. This hospital was later returned to the Mission and medical work was recommenced.

Kongmoon and Shiuchow.—In each of these places there was a British Hospital, the first belonging to the Canadians and the second to the English Wesleyans. Both hospitals were closed for a time and the present position is unknown.

Changsha.—In the march of the Southern army from these towns to Hankow the next place of importance as regards hospitals was Changsha, with a group of institutions in neighbouring towns centred on it. For about a month after its occupation by Cantonese troops peace was maintained, but, with the arrival of communist agents, the story of Canton was repeated on an even worse scale. When these agents travelled on to Central China the position in the Changsha area became decidedly easier again, which explains the reopening of the hospitals here as at Wuchow, Fatshan, and Kongmoon. In Changsha is situated one of the leading medical schools, under joint American and Chinese administration, and a large American hospital. The school has been completely broken up, and the hospital is believed to be closed. An added outrage in this case, as in most of the recent attacks on hospitals, has been the refusal to allow the medical staff to remove their personal property, the authorities claiming that the hospitals and all their contents belong to the local governments. Every hospital in the province of Hunan, with the possible exception of one small institution, has been closed, and in many instances large sums of money have had to be paid to the Chinese employees before even this has been permitted. This robbery has invariably had the connivance, and often the open consent, of the local authorities.

Hankow.—The position in Hankow has been on the whole easier than elsewhere, possibly because it has been more prominently in the public view. Of the two large British institutions here the London Mission Hospital continues to function with comparatively little trouble. The Wesleyan Hospital was the scene of great disturbances at first, but is still continuing its work after a fashion, though under Chinese management and not at all satisfactorily. Details are generally lacking as regards the other hospitals in the province of Hupeh, north of Hankow, with the exception of one large hospital at Siaokan, where the soldiers are occupying the women's hospital and the greater part of the men's hospital, leaving only a few rooms in which a Chinese doctor is attempting to carry on.

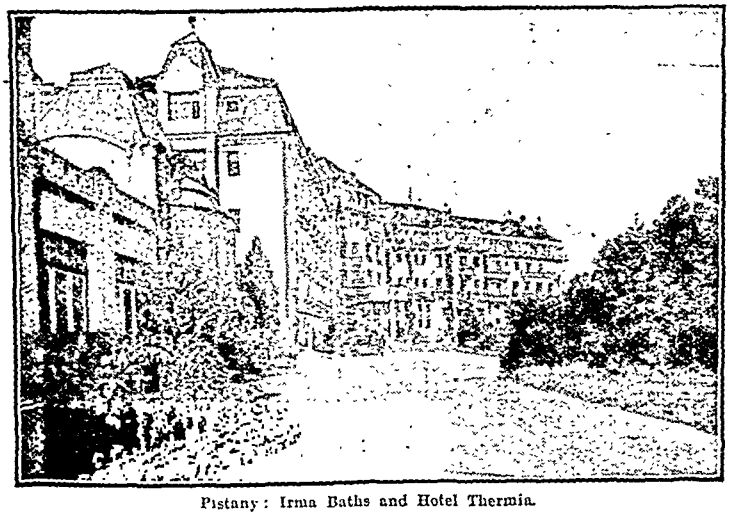
Kiangsi.—The next attack of the Southern army was directed against the province of Kiangsi, where the few hospitals escaped lightly on the whole, probably because the military forces concerned were Chiang Kai-Shek's personal troops, among whom the communist element is lacking. Four of the eight hospitals in this province are known to have continued work smoothly until recently, but owing to the evacuation of all foreigners from this region it is impossible to say what is happening now. No details are yet available about hospitals in Anhwei and Kiangsu as the occupation of those places is too recent for much news to have come to hand. One American and one British hospital in Chinkiang have been looted, probably by the Southern troops and their sympathizers. The American hospital at Yangchow, across the river from Chinkiang, has been completely looted and stripped, apparently by Southern sympathizers and not directly by the army.

Nanking.—In the recent infamous outrages at Nanking the hospitals did not escape. The large University Hospital (American) accommodated in one half of it a large number of wounded Southern troops under the treatment of the foreign and Chinese medical staff. This part of the hospital is believed to have escaped serious damage, but the other half was thoroughly looted by Southern troops in uniform.

Fukien Province.—The 17th Nationalist army, which marched up the coast through this province, is notorious for its *looting* proclivities as regards foreign property. The British General Hospital at Chinchow was seized, the medical officer being threatened by men with revolvers. The place was then used as a barracks and its new buildings were defaced and fouled. Eventually one of the military officers in the city, who had been the patient of the doctor in charge, heard of this and cleared the troops out of the hospital. The same army went on to Foochow and added outrages, one of the principal buildings to suffer being the large British hospital of the Church Missionary Society. The tuberculosis block and the pathological department of the men's hospital were completely wrecked, while the fine new building for women patients was thoroughly looted.

Hangchow (Chekiang Province).—The British hospital and medical school of the Church Missionary Society at Hangchow, with its convalescent homes, maternity hospital, and branch institutions for the treatment of tuberculosis, leprosy, and insanity, was built up by Dr. Duncan Main, who retired last November, after forty-five years of devoted service. The hospital with its annexes contained 500 beds, and the medical school opened three years ago cost over £10,000 to build. The school was recently registered provisionally by the China Medical Association as an approved institution for medical training. When the Southern army obtained control of Hangchow the situation necessitated the immediate withdrawal of all British subjects. The Chinese medical staff was left in charge of the hospital, but immediately after the evacuation of the British hospital was visited by delegates from a "Union to take back the Kwang Tsi I Uen," the Chinese name of this institution. Notices were exhibited announcing the determination of the union to expel from the hospital all except Chinese. On the following day a mob composed of members of the Students' Union, the Anti-Christian Union, the Workers' Union, and other bodies broke into the hospital compound, imprisoned one of the loyal Chinese doctors, and maltreated other members of the staff. The hospital was later commandeered by Southern officials, and is now conducted partly as a barracks and partly as a hospital, with a vague promise that its ownership will be considered later. This appropriation has involved the disappearance of much of the equipment and the use by unauthorized persons of the valuable stock of drugs without any sanction from the real trustees of the property. The one bright spot in the dark picture is the continued loyalty of many of the Chinese staff, who have risked, and even lost, everything while trying to do their duty.

THE SPAS OF CZECHOSLOVAKIA.



A MEDICAL TOUR OF PISTANY AND THE HIGH TATRA HEALTH RESORTS.

Trencsénteplicz.

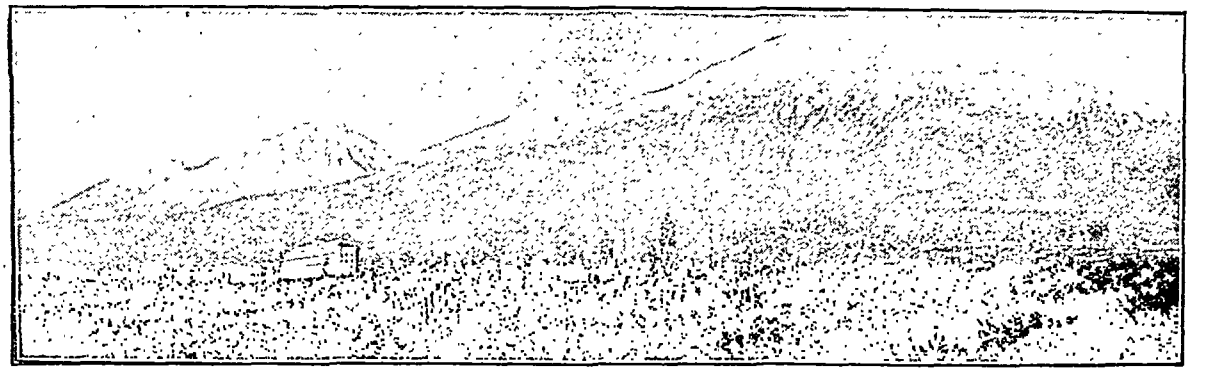
ON April 24th the party of British doctors, whose earlier travels in Czechoslovakia have been recorded,* left Prague for Trencsénteplicz, formerly one of the best known watering-places in Hungary, but now within the frontiers of the new Republic. The ten-hour journey eastwards took them through Brno (Brünn), the capital of Moravia, where they were greeted by members of the Anglo-American colony. Brno has long been famous for its cloth factories, and is to-day a medical centre of growing importance and the seat of one of the two new Czech universities.

Trencsénteplicz is hard enough to pronounce, and its Slovak name, *Trencianské-Teplice*, moves even less trippingly on English tongues. This picturesque little town, 850 feet above sea level, stands in hilly forest country at the foot of the Carpathians, and the virtues of its hot sulphur waters have been known in Central Europe for 500 years. There are now eight mineral springs—six for bathing and two for the "trink-kur." In chemical composition all the waters are much alike; they rise at temperatures between 95.8° and 107.6° F. The new baths, oriental in design, are immediately over the springs, so that little of the natural sulphur gas and radium emanation is lost. Beyond its thermal sulphur baths Trencsénteplicz specializes in hot mud packs, and a descriptive leaflet tells us that in the summer months there is no lack of "dispersing and entertainments which in moderate measures are intended to attain a cheering up of the depressed state of health." It was much too early in the year to form an impression of what this spa is like at the high season; but its natural charm could not escape the eye, and the local doctors were eager to show and explain its equipment to their colleagues.

Pistany: Irma Baths and Hotel Thermia.

THE BATHS OF PISTANY.

Pistany, celebrated for its mud baths, is a beautiful spa whose name, however spelt, is becoming each year better known to British physicians. It lies in the broad valley of the Waag, at an altitude of 500 feet, some 300 miles south-east of Prague, and is well served with trains. Its reputation in the treatment of chronic rheumatic affections, sciatica, and the after-effects of injury is due in large part to the hot sulphur springs and the volcanic mud deposited by them along the bed of the winding river. Both water and mud have to be cooled before use, for their temperature at the source is over 150° F. How and why they leave the bowels of the earth is a question the clinician may leave to geologists, just as their physical and chemical properties are to him of less moment than their indications, mode of use, and effects.



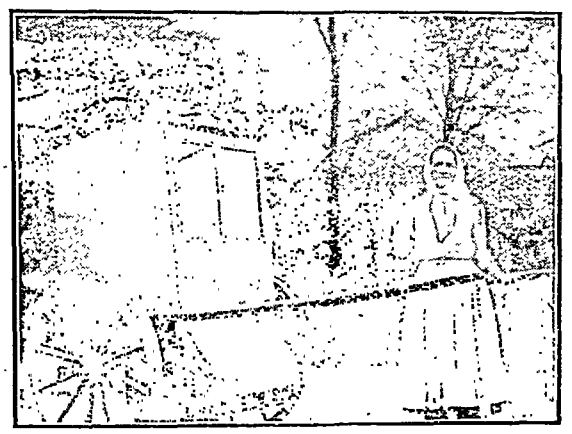
It is forty years since Sir Spencer Wells made a pilgrimage to Pistany, but a reprint of what he wrote in these columns† is still handed to medical visitors from English-speaking countries. A great deal of healing mud and water has come to the surface in the interval, and the primitive village bathing-place of 1887 has been transformed, under the enterprising management of the Winter family, into the luxurious and highly efficient spa of 1927. The two principal hotels are first-rate in all respects, and the larger, the Thermia Palace, leads direct into the baths. The radio-active sulphurous mud is dark greenish-grey, and butter-like to the touch. It is scooped up in wooden buckets, cooled to the prescribed temperature, and clapped upon the skin by deft hands. The patient, thus immobilized and swathed in cloths and blankets, looks very like a mummy, though pinker and less shrivelled perhaps. The clinging mud is presently rinsed off with hot sulphur water, and, after a sweat and a rest and a bathe in the hyperthermal pool, those who have any distance to go are taken back to bed in a wheeled sedan chair of the kind shown in Dr. Crocket's photograph.

The hospitality of Pistany was even more abundant than its balneological literature, and that is saying much. The party was received with every courtesy at the railway station and welcomed later at dinner in the Hotel Royal. Next day, having tried the hot mud and learnt by personal experience that after a bout of fever rest is needed, they were shown over the Irma Bath Establishment, and the Pro Patria Hospital for the free bath treatment of insured persons; and Dr. A. Reichart gave them an interesting address on the action and uses of mud baths and demonstrated the Pistany pack. Lunch was followed by a lantern lecture on the history of the spa by Dr. Paul Veres, and a visit to the sanatorium on the river-side kept by Drs. L. Schmidt and E. Weisz. At a banquet in the Thermia Palace Dr. Smély of the Czech Ministry of Health spoke for his government; Dr. Schmidt for the [illegible] medical profession; and Mr. Imri Winter [illegible] us of the spa, for the baths management [illegible] that the visitors heard for the first time a real gipsy band and saw peasant dances in the Slovak national costume.

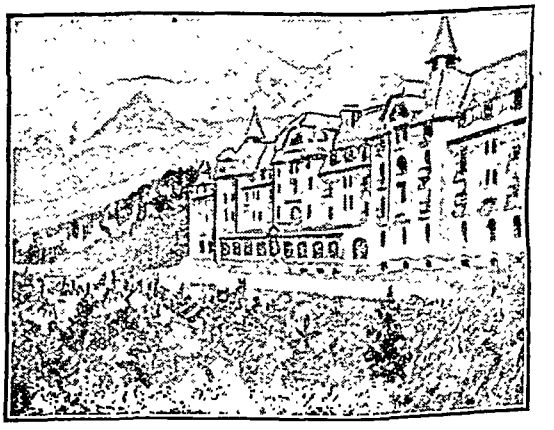
Here it should perhaps be said that all through their trip they had skilled linguists with them. Mr. Henry Baerlein, the writer and traveller (who had had a big share in planning the tour), shepherded the party as far as the Czech frontier, and often helped them and their hosts to make friends by his lively impromptu translations. Dr. Karel Driml, head of the propaganda department of the Czech Ministry of Health, went everywhere with them in his own country and spent himself in their service; at a moment's notice he would give the gist of a speech, in English or Czech or German, to those who had not followed a word of it. And as for the bothers of travel in a strange land, these were all taken over and smoothed out by Mr. John Zlámal, of Pistany, secretary of the Union of Slovakian Spas.

* BRITISH MEDICAL JOURNAL, May 14th, pp. 885-85; May 28th, pp. 966-68.

† Notes on a Visit to Pistyán, BRITISH MEDICAL JOURNAL, May 5th, 1883.



Palace Sanatorium, Novy Smokovec, High Tatra.



THE HIGH TATRA.

The central and highest group of the Carpathians, known as the High Tatra, is the most impressive mountain range in Europe, for it rises sheer out of the surrounding plateau, like a vast wall, 8,000 feet and more above the sea.

Leaving Pistany behind, with the regret to which they had become hardened after a kaleidoscopic fortnight among the spas, the travellers headed north and then east again for the last stage of their outward journey. Five or six hours in the train, towards and between the foot-hills of the Carpathians, brought them abruptly face to face with High Tatra, towering over the landscape. Then from the junction at Poprad Velká they mounted to Tatranská Lomnica, one of the many small health resorts dotted about the lower slopes of the range. This, "the Czechoslovakian Davos," faces south, at an altitude of 3,000 feet above the sea; it is one of the State-owned health resorts, like Strbské Pleso, which stands 1,400 feet higher on the borders of a mountain lake.

Pistany: Wheeled Sedan Chair.

Tatranska Lomnica: Grand Hotel Praha.

The Alpine scenery around Tatranská Lomnica is very beautiful. At every turn one sees two huge snow-capped peaks rising above the pine woods. On their far side is Poland. The Grand Hotel Praha, a luxurious building, does not open so early in the year, and the visitors put up at the châlet-like Slovensky Dum and feasted at the Lomnica—two inns that lay themselves out for winter sport. Here they tasted Tokay, and met a group of the sturdy ambulance doctors who take medical charge of a scattered mountain population. Speech-making became more frequent, though not more formal, in the thin, sharp air of the Slovak highlands.

On the following afternoon they passed on to Novy Smokovec, a climatic station of growing repute, and spent the night as the guests of Dr. Nicholas Szontagh at the Palace Sanatorium. This is surely one of the finest institutions of its kind in Europe. It is, in fact, a palatial sun-trap, with the mountains behind and a wide valley spreading below. Many cases besides those of tuberculosis are received. The building is so planned that each of the five upper floors has a south balcony running from end to end, and nearly every bedroom leads straight out on to its own partitioned and glass-roofed piece of verandah, so that a patient can rest on a couch in the open or be wheeled into the sunshine on his bed. The whole lay-out of Dr. Szontagh's hospital-hotel is most ingenious, and the life of every patient appears to be most carefully ordered. Some idea of its situation at the foot of High Tatra may be got from the illustration at the head of this page. Strbské Pleso lies to the left nearer the snow line, and Tatranská Lomnica a few miles away to the right. All these resorts are linked up with one another, and with the main line junction at Zilina, by electric railways.

The last twenty-four hours before beginning the long journey home were spent partly at Novy Smokovec and its neighbour Stary Smokovec, looking over their sanatoriums large and small, or climbing hills; and partly in taking train up the mountain side to Strbské Pleso, with its delightful hotels at the top of the world. On the way down the travellers stopped at Tatranská Polianka to see Dr. Gúhr's admirable sanatorium for the treatment of exophthalmic goitre. In the High Tatra, just as in Bohemia and the eastern spas, kindness awaited them at every halt, and this medical tour through Czechoslovakia might almost have been a royal progress, so much honour was paid them from day to day.

It will be gathered from what we have written that Czechoslovakia takes its spas very seriously. Not only those owned by the State, but all the health resorts of the country, are watched over by the Government with a fatherly eye. The Ministry of Health periodically sends out a medical officer to inspect and advise, and the State railways make a large reduction in fares to visitors who mean to spend more than ten days at one or other of the resorts and give proof of their intention when crossing the frontier. How to get this concession may be learnt by writing direct to the management of the spa, or to the "Cedok" Tourist Bureau, Mikulandská 7, Prague II, or to any agency of the Cie Internationale des Wagons Lits.

Nova et Vetera.

THE FIRST OPERATION OF SYMPHYSIOTOMY.

IN the year 1768 a young medical student named Sigault suggested to the Académie de Chirurgie in Paris that women in labour in whom the pelvis was considerably contracted might be delivered with no serious risk after division of the symphysis pubis, and that this operation might take the place of Caesarean section. The proposal was ridiculed, and for many years nothing more was heard of the subject. In 1777, however, Sigault, who had always had the greatest belief in his operation, found a patient for whom he thought his procedure was justifiable. She was a Madame Souchot, a small deformed woman with a pelvis so narrow that natural delivery of the child was impossible. With the assistance of the well known surgeon Le Roy he performed the operation of symphysiotomy, and the result was most satisfactory, both mother and child surviving. Sigault at once became famous. The Académie de Médecine struck a medal in honour of the operation, and the operator was received with open arms. M. Le Roy thus describes the case.

I observed that the child presented by its feet, that the orifice of the uterus was much dilated, and that the diameter, from the anterior to the posterior part of the pelvis, did not exceed two inches and a half. I told M. Sigault that as the diameter of the child's head at its birth usually is at least three inches and a quarter, it would be impossible for it to be delivered at an aperture of only two inches and a half; that consequently she must submit to the Caesarean operation, or that which we intended to substitute for it, to which last she consented.

Everything being got ready, we folded the mattress three times, and placed her on it. We began to feel for the middle part of the cartilage of the symphysis, which we readily discovered by the finger. I advised M. Sigault to begin the section of the superior part of the symphysis, but not above the pyramidal muscles, and to do it by two incisions. First, to divide the integuments as far as the middle of the pubes, while I held the lower part downwards, and then to begin the section of the cartilage. Secondly, to finish the incision of the integuments, without any fear of haemorrhage obstructing him in the section of the cartilage. M. Sigault had nothing but a common bistoury to perform this operation with. The thighs being opened and raised, he performed it in the manner mentioned. The moment the separation was complete, the pubes parted, as if the string of a bow had been divided, and receded to each side under the integuments. I immediately began to extract the child after M. Sigault had broken the membrane, and brought the feet as far as the os externum. I first made myself sure of the extent of the separation which we had gained by the section [that is, the side-to-side diameter], which measured two inches and a half, an extent somewhat more than that which I had gained upon the body of Mrs. Brasseur, which gave me pleasure. [Mrs. Brasseur was a woman on whom M. Le Roy made trial of the operation directly after her death. An attempt had been made by an incompetent midwife to deliver her of a child.] The child's heels were turned on the right side, and I extracted the body by gentle efforts, which I directed towards the lateral parts entirely, and not to the spine. I disengaged the left arm, and then the right; the head being still above the brim of the pelvis, I applied my hand to the face, which corresponded with the symphysis of the left ilium; I opened her thighs as far as I could, and fixed the largest portion of the right parietal in the separation. The integuments projected; I made the left parietal answer to the right lateral side of the hollow of the sacrum; afterwards, upon raising the body of the child, I drew out the left lateral side of the head, while at the same time with the right hand applied to the nasal fossa, I brought the chin downwards. By these united efforts I overcame the greatest resistance at the brim of the pelvis. When it had now gained the hollow of the sacrum, I brought the occiput between the separation, and disengaged the chin at the inferior part of the os externum by rais body. The rest of the body followed pres patient was delivered, to her great joy, of a h thighs being lowered, the separation appeared eight lines. I immediately extracted the pl the uterus began to contract itself exceedingly.

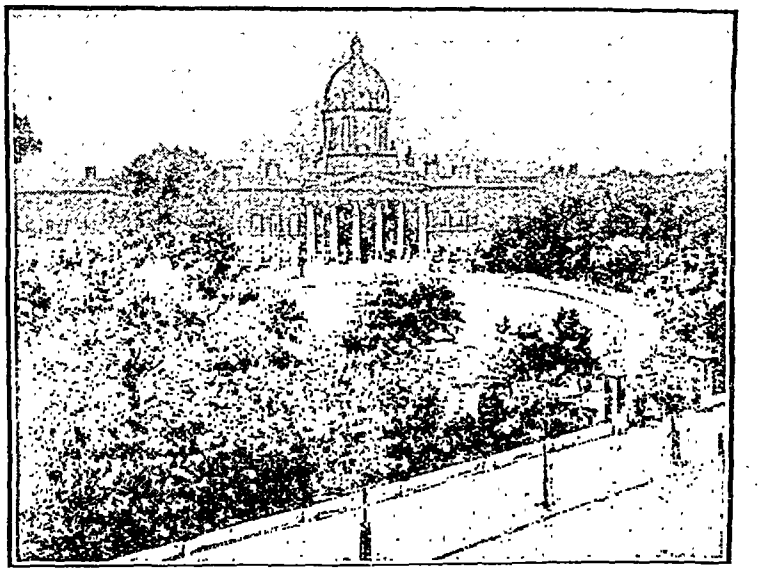
During the operation, which was neither ve tedious, the woman lost very little blood, an being called in could scarcely give credit to s speedy a delivery. We applied some lint to removed the patient on the mattress in order to Upon the least opening of her thighs she felt v in the left posterior side of the loins and pelv a napkin by way of a bandage, to keep the p position, to which we fastened two ribands the right, the other on the left, and broug the thighs in order to tie them before. When found her pulse was not affected, and, enraptur a mother, she requested us to give her the ch suckle it.

BETHLEM ROYAL HOSPIT

ITS APPROACHING REMOVAL.

THE transference of Bethlem Royal Hospita site in Southwark calls to mind its history, w in the annals of English institutions devote and treatment of mental and nervous di probably but little known that its foundati as far as the year 1247, and that the work by Simon Fitz-Mary has been carried on wi ever since. In 1546 it was re-founded a Charter by Henry VIII. It is of special in the early activities of Bethlem Hospital, f or thereabouts there was not a single pul borough asylum, and such institutions as c only due to royal or private benevolence.

Up to the commencement of the nineteent mentally afflicted were housed in gaols, hou tion, poor-houses, and houses of industry. far away when the conception reigned that afflicted were demoniacally possessed and tre consisted of exorcism through punitive mea later theory that mental disease had its orig and humours within the individual, which me by bleeding, purgation, starvation, the us and mechanical restraint.



Since the first appointment (in 1845) o Commissioners, who were succeeded at the e the Board of Control, the attitude to the me has been ever progressive, and in this huma tific advance Bethlem Hospital has always forefront. From the year 1815 it has occupi site on about 10 acres of land, but its envi was that of fields and open spaces. How, d century, bricks and mortar have encroached hemmed it in is, unfortunately, only too p one who knows the neighbourhood.

Notwithstanding its age, a visitor would, astonished to find that in its equipment t evidence of modernity which could hardly unfavourably with much later built insti long series of physician superintendents and medical staff have always been psychiatris and the efficiency of the hospital in the realr and treatment and education has developed on the most up-to-date lines. It is now, for years, the great centre for the teaching of psychological medicine, and its value in can hardly be overestimated. Now incorpor University of London, many students from pitals are taught by their respective lecture clinical instruction are held daily; and two c Diploma in Psychological Medicine are h Much interesting and fruitful research has c the Pathological Laboratory, while through t of the president of the hospital, Sir Charles V

one of the best and most modern x-ray installations has been in use for some years. In fact, no stone has been left unturned in the provision of such a scientific equipment as shall make it possible to attack mental disease from every possible angle.

The inauguration of an out-patient department in a separate building in 1919 showed how much in the vanguard of modern medicine the authorities were. Here the neurologist and psychiatrist have, hand in hand, studied the intricacies of early psychopathological symptoms, with the ideal aim of prophylaxis in view. Notwithstanding the fact that the hospital so admirably fulfils its medical and academic functions, it has to follow in the train of other institutions and seek its habitat further afield where greater space and purer air may add still more to its scientific value. Though there are many advantages which naturally accrue to its present central position, it is evident that these are outweighed by the benefit which more spacious buildings in a more open and yet accessible neighbourhood will bring to the patients, whose welfare must, of course, be the paramount consideration.

Psychiatry has advanced in many directions of late years, and in the new hospital the accommodation will be so planned that the various types of cases can be differentiated and segregated in a way that will not only add to the comfort of the patients, but tend to aid still further a recovery rate which already on an average is 50 per cent. or more. On an estate of 350 acres known as Monks Orchard at West Wickham in Kent, between Addington and Bromley, the reborn Bethlem Hospital will be constructed on the most modern lines for the accommodation and treatment of about 250 patients. There are many reasons why the old caravanserai building is unsuitable, and the detached unit principle which will be adopted is one which lends itself to the most recent ideas concerning psychiatric administration. Such a system undoubtedly to a great extent renders the environment less like an institution and more homely, and these are the great factors in creating an atmosphere conducive to the patients' well-being. It will thus be possible through the separate units, each with its large special garden for exercise and recreation, to carry out the all-important practice of classifying the inmates in accordance with their adaptive needs.

Bethlem Royal Hospital.

Offices for the various departments will be provided in the main administrative block. In the science and treatment unit will be the pathological, bacteriological, psychological, dental, and electrical departments, and a lecture theatre and museum. This will render the scientific equipment of the hospital such that it will be able to carry on its academic work on the most up-to-date lines and enhance its already high status as a special medical school of the University of London. Though in the different hospital units provision will be made for all methods of special treatment, these, with the addition of hydrotherapy, massage, and physical culture, will be carried out principally in the main treatment block.

Of late years occupational therapy has rightly been much developed, and this feature has received special consideration. Not less important is the organization of facilities for both indoor and outdoor amusement. Within, social evenings, whist drives, concerts, dances, cinema entertainments, will be arranged for in the large entertainment hall. Without, patients will be stimulated to the external interests of sport, gardening, natural history, and agriculture.

There is no doubt that in the past mental hospital construction has been of such a nature that voluntary boarders or those who have only just passed over the psychotic threshold have had to be associated in the wards with patients who evince acute mental reactions. In the New Bethlem an integral part of the institution will be the convalescent unit, where this patent drawback can be obviated. Here incipient cases, mild types, and those approaching normality can find everything most calculated to give peace of mind and aid recovery.

Notwithstanding all these excellent arrangements for the main organization of the hospital, it has to be realized that without a suitably trained nursing staff any medical efforts to combat mental illness tend to be much impeded or nullified. In order to attract the type of nurse who will be competent to form an intelligent understanding of the meaning of mental disorder and create that atmosphere which is so essential to her charges, she must be catered for in a worthy manner. The hospital will not only see that she has every facility for good training, but the Nurses' Home, with its library, recreation hall, and provision for all forms of amusement, will give her that happy and comfortable home which is the more imperative considering the arduous nature of her duties. Each nurse will have her own separate bedroom, and in her hours of leisure will be able to detach herself from the hospital environment, and so gain that mental rest which she so well earns.

It seems, then, when we review the constructive plans and organization of the New Bethlem Hospital, that nothing will be left undone to render it psychiatrically efficient in every sense of the word, and that the highest aims of modern treatment and the dissemination of knowledge of psychological medicine will be amply fulfilled.

The conservative spirit necessarily reigns within most of us, and the removal of an old London landmark will be regretted by many. Bethlem has always held a special place in the world of mental medicine, and those of an older school have noted with great interest the gradual evolution of Bethlem Hospital until it has reached its present position and holds the highest rank for efficiency in every respect. Nevertheless, circumstances have made it necessary that the hospital should find a site where the great work can be carried out with still further opportunities of advance and where those mentally alienated may have an even better chance of regaining *mens sana in corpore sano*.

Of late years lunacy administration has undergone much unfair criticism from those who, doubtless with the best intentions, do not understand the difficulties that must always beset its path. The Royal Commission on Lunacy and Mental Disorder, which issued its report last year, made many recommendations. All these will be fundamentally met in the New Bethlem Hospital, which, soon to arise, will mark another milestone in psychiatric history.

British Medical Journal.

SATURDAY, JUNE 4TH, 1927.

A GENERATION PASSES.

THE British Medical Association has entered upon the fourth generation of men since its foundation in 1832. It was early in the third generation—almost exactly a generation ago—that the Annual Meeting was last held in Edinburgh. It is appropriate, therefore, in view of the forthcoming meeting, to look back upon the changes in medicine during the past thirty years. The task is not easy. However rapid the changes may be, they seem to occur in such natural sequence during the observer's lifetime that he has usually forgotten the beliefs and conditions under which he worked at the outset of his career. It is difficult, for instance, to remember that in 1898 no doctor could trust a motor car to take him on his rounds.

Some indication of the advances that have been made in medicine, and of the changes in medical interest, may be found in the list of Sections in which discussion took place in 1898 and will take place this year. At the meeting in 1898 there were sixteen Sections; this year there are twenty-one. Of these twenty-one, fourteen are practically identical with those of 1898. Two of the former series no longer exist—namely, that of Medicine in Relation to Life Assurance and that of Anatomy. Of the seven newer Sections in the 1927 list, that of Radiology at once recalls a line of progress which has been of inestimable benefit to medicine. The Section of Medical Sociology typifies the closer relationship into which the medical man has been brought with large questions affecting the community as a whole. His appearance in this role is emphasized also by the Section of Venereal Disease, and, apart from its acknowledgement of the achievements of the incoming President, Sir Robert Philip, by the Section of Tuberculosis. The widening of interests in the medical profession is shown by the Sections of Comparative Medicine and the History of Medicine. Why forensic medicine was considered unworthy of a Section in 1898 we do not know; the police surgeon was even then of sufficient importance, though the difficu't question of alcohol and the motorist had not arisen.

Looking at the subjects to be debated at Edinburgh in July, some may suggest that the medical mind is still agitated by questions which were unanswered in 1898. But many others reveal progress which was then unthought of. Such are the results of insulin in the treatment of diabetes mellitus; the action of ovarian extracts; the influence of internal secretions on the sex characters; and the revolution in the views on cardiac disease. New methods of diagnosis are to be found in the Schick and Dick tests, and in the examination of cerebro-spinal fluid in venereal disease. A newly distinguished disease is represented by epidemic encephalitis; new treatment by a discussion on ultra-violet emanations; and a new relation of the State to the individual and to voluntary effort in the debates on the State's duty to the nation's food supply, regarding instruction to parents, and on the future relationship of municipalities to the voluntary hospitals of this country. Many of these topics would have gladdened the heart of the bygone generation; others might have shocked those trained in principles of *laisser faire*.

Formerly, in addition to the new President's address, general addresses were given in medicine, surgery, and psychology. In 1898 the address in medicine, on "The Toxic Origin of Disease," was given by Sir Thomas Fraser. In surgery Mr. Thomas Annandale described "The Present Position of Surgery"; and Sir John Batty Tuke opened the Section of Psychology with an address on "Modern Conceptions of the Etiology of the Insanities." The President in 1898, Sir Thomas Grainger Stewart, surely in prophetic vein, dealt with "The Reciprocal Duties of our Profession to the Community and of the Community to the Profession." He thought that professional customs did not lend themselves readily to the issue of clear and popular statements by the leaders of medical opinion. He desired to see the Legislature refer questions to the British Medical Association. He wanted the Local Government Board to be entrusted with every question affecting the prevention of disease, and money of the State spent on the endowment of research. As an argument to show that knowledge provided us with precautionary measures, he pointed out that the tuberculosis mortality had fallen by one-third in the previous thirty years. The addresses in medicine, surgery, and psychology are no longer given; but the Presidential Address this year will be delivered on July 19th by Sir Robert Philip, who was secretary, with Mr. John Shaw McLaren, to the meeting in Edinburgh in 1898. The title of the address will probably be "The Strategic Front of Medicine To-day," and it will, we understand, be in part reminiscent and in part prospective.

A special feature this year is the decision to hold the Edinburgh celebrations of the centenary of Lord Lister's birth during the Annual Meeting of the British Medical Association. To commemorate the event a Lister Memorial Volume, edited by Dr. Logan Turner and containing contributions by well known medical writers, will be presented to each member of the Association who attends the meeting. Among the exhibitions at Edinburgh there will be a museum of Lister relics, and a [illegible]m, which is now a regular feature.

In 1898 there was no Representative Meeting. Reconstitution of the Association had not taken place, and it was not until 1903 that the first Representative Body met at Swansea. Before that date the only opportunity available to the ordinary member for criticizing the administration of the Association or airing his views was at the Annual General Meeting. The reconstitution was a sign of the adaptability of the Association to changing circumstances, and helped to further the desire of Sir Thomas Grainger Stewart that the Legislature should refer questions to the British Medical Association. If anyone requires evidence of the value of the change, it is only necessary to compare the position of the panel doctor in England with that of the insurance doctor in Germany, who is still ground under the heel of the Krankencassen, or approved society, officials. In England, where a powerful professional organization existed before the Insurance Acts were thought of, control of the doctor became vested in very different hands.

Those who attend this year's Annual Meeting will receive from Edinburgh no less cordial welcome than in 1898. They will find that one thing has not changed one whit in the course of a generation—namely, Scotland's reputation for hospitality. They will be offered a scientific programme of the greatest interest, social amenities, and the opportunity of seeing some of the beautiful scenery of Scotland. Details of

all this will be found in the SUPPLEMENT. In preparing its welcome Edinburgh may well have felt some trepidation, seeing that the body from which her guests were drawn in 1898 has nearly doubled its membership, having grown from 17,700 to 32,300. But Edinburgh will be justly proud of the part which she has taken in achieving this success. The assumption of the office of President of the Association by the distinguished secretary of 1898 marks continuity with the past, gives prestige in the present, and assures yet greater achievements in the future.

LOCAL IMMUNIZATION IN SEPSIS.

WHEN Professor Besredka, after much investigation, expressed the opinion that the reaction of the body to some diseases was not general, but local, it was at once evident that important therapeutical conclusions might be drawn. In a book,[1] published two years ago, he dealt with anthrax bacilli, staphylococci, and streptococci as organisms in which the processes of infection and immunization were primarily in the skin.

Superficial septic conditions obviously afford a good field for experimental study, and an attempt was made to prepare some agent which could be applied locally in order to attack the infecting organisms directly or indirectly. Making use of the well known fact that bacteria, when freely grown, produced poisons inimical to themselves, cultures eight to ten days old were filtered and their toxins removed by heat in order to make application to septic areas safe; to these preparations the term "antivirus" was given. Recent reports indicate that such bacterial filtrates may have a therapeutic value. H. Lehndorff and Margarethe Brumlik[2] demonstrated that each antivirus had a specific inhibiting effect on the growth of the group of organisms from which it was prepared, and also increased leucocytic phagocytosis. A hanging-drop preparation of a twenty-four-hour culture of *B. coli* showed diminished motility when the specific antivirus was used. Since the antivirus is an alkaline fluid of the same *p*H as the body fluids, it does not injure the tissues when brought into contact with them in order to produce its full local effect. Lehndorff and Brumlik, and also Besredka, recommend that for ordinary pyogenic infections a polyvalent antivirus consisting of a mixture of streptococcal and staphylococcal antivirus is desirable. P. Moritsch and R. Oppolzer, however, employed a monovalent preparation in a certain number of their cases, restricting the polyvalent antivirus to those in which a mixed infection seemed probable or had actually been demonstrated in smears and cultures. When the antivirus was applied as a wet dressing in fifty-two cases of such suppurative conditions as acute mastitis, paronychia, whitlows, and furunculosis, in conjunction with the usual simple surgical measures, these investigators found that the exudate from the wound diminished, pain was relieved, the signs of inflammation rapidly subsided, and healing was accelerated. It produced no effect, however, when applied to the unbroken skin over an abscess, and failed in one case of severe generalized erysipelas. As already noted in the *Epitome* (April 16th, para. 433), P. Tron found the treatment valuable in puerperal sepsis, while Schlein has obtained beneficial effects in a small number of cases of buccal sepsis from a mixed antivirus containing staphylococci and streptococci. It relieved pain in acute periodontitis, and one case of severe ulcerative stomatitis which had resisted other forms of treatment for three months subsided three days after the application of the antivirus.

Various theoretical explanations of the effects observed have been offered. Lehndorff and Brumlik consider that each antivirus, besides having a damaging effect on a specific type of organism, also modifies the tissues, rendering them a less suitable nutrient medium for bacterial growth. These authors do not regard antivirus as in any way related to Twort d'Herelle's bacteriophage, though they think that the activity of ferments may play some part in the process. Citron explains the results as due, not to a direct action on the organism, but to a local immunization of the tissues. Besredka has suggested that a soluble antivirus is liberated ordinarily during the phagocytosis of organisms, and that the "sessile phagocytes, or the reticulo-endothelial cells, when artificially impregnated with antivirus, become desensitized to pathogenic organisms, and are thus enabled to engulf and destroy large numbers as freely as if they were non-pathogenic. Though these hypotheses are as yet unconfirmed, the clinical results obtained appear to indicate that further investigations may produce results of considerable practical as well as theoretical importance.

MENTAL DEFICIENCY ADMINISTRATION.

THE Report of the Board of Control for 1925 was issued nine months ago. An article epitomizing some portions of it was published in the JOURNAL of September 11th last (p. 487). That part of the report which deals with mental deficiency has not, perhaps, received as much attention from the medical profession as it should have had. Such attention will probably be stimulated by a memorandum on the subject drawn up by a county medical officer of health, approved by the Association of County Medical Officers, and more recently adopted, without material alteration and after perhaps insufficiently detailed consideration, by the Council of the Society of Medical Officers of Health. The attitude towards the Board of Control disclosed by the memorandum is one of active hostility, and the criticisms of the Board's report and supposed intentions are not restrained. It would, however, easily be possible for the Board to reply that its intentions have not always been correctly described, and that a more careful study of some of the paragraphs of its report might have prevented what is an evident misunderstanding of their tenor.

Nevertheless, the main principle for which the memorandum contends—that the work of mental deficiency administration should not be isolated from all the other medical work of a local authority, but should be regarded as an integral part of public health work under the administrative control of one principal medical officer in each area—has on more than one occasion been declared emphatically as part of the policy of the British Medical Association. It cannot be gainsaid that there is a real necessity for insistence on this principle at the present time, and that there is considerable anxiety as to the attitude of the Board of Control with regard thereto, and, indeed, as to the full appreciation by that Board of the facts and problems of public health administration in general, and of the relation of those facts and problems to its own special field. The circumstance that this special field is concerned only with mental defects and disorders will not justify administrative isolation. The Ministry of Health Act makes it the duty of the Minister to "secure the preparation, effective carrying out, and

co-ordination of measures conducing to the health of the people, including measures for the prevention and cure of diseases and the treatment of physical *and mental* defects." The Chief Medical Officer of the Ministry of Health, in his report for 1925, said that the problem of the mentally subnormal child " should not be dealt with only as a form of curative or ameliorative medicine, but as an integral part of preventive medicine." The Report of the Royal Commission on Lunacy and Mental Disorder said (para. 38): " It has become increasingly evident that there is no clear line of demarcation between mental illness and physical illness "; and (para. 50): " The problem of insanity is essentially a public health problem, to be dealt with on modern public health lines." In that unification of public health administration, both centrally and locally, for which the Association is striving in the interest of national health there is no propriety in excepting any particular health service. It is unfortunate that the school medical service is still regarded primarily as part of our educational machinery and not as part of our public health machinery so far as its administration is concerned; though the effects of this separation are minimized by the happy circumstances that the Chief Medical Officer of the Ministry of Health and the Chief Medical Officer of the Board of Education are the same person, and that in almost all areas the medical officer of health is also the school medical officer. On the ground that mental deficiency in the child cannot be divorced from the work of the school medical service, as well as on the ground that the mental deficiency in the adult or adolescent cannot be properly considered apart from the same condition in the child, it is desirable that responsibility for these spheres of health work, as well as the others, should be placed upon one chief administrative health officer in each local government area. Any tendency of the Board of Control to encourage action on lines contrary to this principle must be carefully watched; but it may still be hoped that no such tendency will appear.

Even were such administrative unification actively encouraged or firmly established, however, this would not refute the statements of the Board of Control in its report: (1) that a large number of local authorities are still failing, in a greater or less degree, to carry out their statutory duties in connexion with mental deficiency; and (2) that there are a not inconsiderable number of members of the public health service, whether medical officers or their lay subordinates, who show very little or no interest in, and but slight if any knowledge of, this work. The memorandum of the Association of County Medical Officers and the Council of the Society of Medical Officers of Health would appear to be intended to imply that these statements are incorrect, but no one with a wide knowledge either of educational administration or mental deficiency work will be likely to question their truth. Such blame as there may be does not lie wholly with the local authorities, or still less with their officers. Pressure from the Board of Control upon what may be regarded as the most backward authorities can scarcely be described as severe, and for some time past the President of the Board of Education has been discouraging education authorities from making that provision for mentally defective children which is part of their statutory duty. When the council of the local authority in these circumstances deliberately neglects or has only a perfunctory regard to this part of its work, the medical officer and his staff can scarcely be blamed if they devote their energies to those public health duties in which they can do effectiv and are less zealous to acquire skill in or de time to spheres of work in which they employing authority will take no effectiv Nevertheless, there are many areas in which authority is primarily at fault, and some in responsible medical officer and his subordi imperfectly equipped for this portion of their

The duties of the local authority towards deficient persons are (1) ascertainment, (2) so far as possible, between the ages of 7 and (3) care by way of supervision, guardianship dential institution provision. The first and these lie mainly with the education authority, with the mental deficiency authority. None is easy to perform completely and effectivel all require a good deal of special medical ski as vigilant and instructed lay help. Over a of the country there is a disastrously incom vision both for education and for supervision and though ascertainment is supposed to be u carried out, it is clear that in many cases both persistence are lacking with regard even to that very varying standards are applied. instances no active search for defectives is n only those cases are known which are casually from time to time at the county or borou In other instances the educational or officers of the authority, or the relieving of directed to report any cases they come a as a rule they have no special training in t Further, where the work of ascertainment mainly by a voluntary association there is a of practice. In some areas every case notice is handed on to the local authority; only those which, besides being mentally defe " subject to be dealt with " under the Acts.

It is scarcely to be wondered at, therefore Board's figures may be challenged; or that should insistently demand some degree, or degree, of skill and training in this w those persons, whether medical or lay, in wh is placed the duty of ascertainment—still ascertainment, classification, and supervisio we believe, the medical officer of health shou responsible person, whether or no he has o (either as a school medical officer or otherwis medical man or woman with special dutie connexion, it is essential that he should hi considerable knowledge of this subject; and with regard to mental deficiency are assigned nurses, health visitors, or others on his s equally essential that they should have re appropriate training. This is emphatically with regard to any medical officer who is r for the actual certification of cases; and in nexion it must be remembered that the D Public Health does not involve such t experience, that even the Diploma in Psy Medicine may be held by a person who nothing of mental deficiency work, and medical superintendent of a mental hospita not interested in defectives, has usually lit ledge of home conditions, and is not always with the general public health work in his these circumstances it is fortunate that th Association for Mental Welfare has provid courses of training, which are officially recog social workers, and also, in conjunction University of London, for medical officers. It that the services of the Central Associatio and in other directions, should be acknowledg

ATTENUATION: "A STUNNING SUCCESS."

LAST Thursday was the forty-sixth anniversary of the crucial practical test of the validity of Pasteur's method for the protection of farm animals, especially sheep, against anthrax. On March 21st, 1881, he had made a final report to the Académie des Sciences on his experiments to produce anthrax bacilli of a greatly reduced degree of virulence. The bacillus would grow freely in a suitable medium, but its virulence was greatly attenuated or abolished. At the end of April, 1881, Pasteur arranged with the president of the Agricultural Society of Melun to put preventive inoculation to a practical test. He proposed that sixty sheep should be used for the experiment, but consented, at the request of the president of the society, to extend the experiment to ten cows. He foretold that after inoculation with a very virulent virus all the sheep not protected by inoculations of attenuated virus would die; that all the cows not so protected would be at least made ill, and that some would die; that the protected sheep would survive inoculation with this very virulent virus, and that the protected cows would not be made ill. The experiment was made at the farm of M. Rossignol at Pouilly-le-Fort, Melun. The animals actually used were 58 sheep of both sexes and of varying age; 2 goats, 8 cows, 1 ox, and 1 bull. On May 5th 24 sheep, 1 goat, and 6 cows were inoculated with the attenuated virus. On May 17th they were again inoculated with a second virus less attenuated than the first. On May 31st 60 animals were inoculated with a very virulent virus—namely, 48 sheep, of whom 24 had been vaccinated and 24 not; 2 goats, 1 vaccinated and 1 not vaccinated; 10 bovine animals, 6 vaccinated and 4 not vaccinated; 10 sheep, neither vaccinated nor inoculated, were kept as controls. Forty-eight hours later (on the morning of June 2nd) a large number of spectators assembled at the farm. It was an anxious moment for Pasteur, because, though he was certain of his laboratory facts, a practical test under farm conditions was another matter, for so many accidents might happen; his mind had, however, already been relieved by the receipt of a telegram on the previous evening telling him that things were turning out as he had foretold; the telegram ended with the words "stunning success." Pasteur reached the farm at 2 o'clock on the afternoon of June 2nd. He saw laid out the carcasses of 21 of the 24 sheep which had not been protected by inoculation of the attenuated virus, and of the one unprotected goat. The 24 sheep and the goat protected by inoculation appeared to be in good health. None of the bovine animals was dead, but the 4 unprotected presented extensive oedematous swellings around the point of inoculation, and by the following day the swellings were much larger and the animals had fever. The 6 bovine animals protected by the attenuated virus did not suffer any elevation of temperature, swelling, or loss of appetite. By the evening of June 2nd the three remaining unprotected sheep were dead. The success of this farmyard experiment was at once widely acknowledged by practical veterinarians, and the importance of the principle established was by degrees gradually recognized by the medical profession. From it may be dated the beginning of the enormous amount of experimental and clinical work which has been done on attenuation and immunity.

THE COLSTON RESEARCH SOCIETY, BRISTOL.

THE universal respect in which the memory of Edward Colston, the philanthropist of Bristol, is held in his native city is reflected in the societies which have been established there from time to time to keep his memory fresh. The parent society still holds its meetings; but as these are conducted in private the nature of its deliberations is unrevealed, although it is known that there was a time when heavy feasting and hard drinking formed part of the agenda. Then there are the opposing political societies—the Anchor and the Dolphin—for those who delight in political fisticuffs; and a haven of peace for those who have forsworn politics for good—the Grateful. More recently a desire arose to make some adequate commemoration of the educational, as distinguished from the purely charitable work of Colston. The late Mr. Walter Reid, founder of the *Western Daily Press*, with this end in view, proposed to establish another Colston Society, which should not only commemorate Colston, but also work for the conversion of the Bristol University College into a university. A Colston Research Society was accordingly founded, and it exercised considerable influence in securing the University Charter which was applied for in 1903. In recent years the funds of the Research Society have been used in grants for definite branches of investigation, and the same broad and varied outlook has been exhibited by the committee in the application of their grants as the townsmen have shown in the activities of their various societies. Thus, the list for the current year includes such items as the use of heavy fuel in engines, the processes of soap-boiling and tanning, the measurement of temperature and pressure in internal combustion engines, certain matters of literary and artistic import, and, not least in importance, the study of rheumatic heart affections. At a dinner given by the Research Society at the Victoria Rooms, Bristol, on May 23rd, at which Sir William Hardy and Sir Humphry Rolleston were the guests of the evening, the honorary secretary, Mr. J. A. Arrowsmith-Brown, announced that a sum of £200 had been given by six subscribers for a research fellowship in connexion with the Institute of Cardiac Research, which is to be established shortly at the Bristol General Hospital and will be equipped by the University. Work in relation to heart disease has already been assisted by the society, and is being carried out under the supervision of Dr. Carey Coombs; the fellowship will enable the whole-time service of a skilled assistant in the work to be secured. By the generosity of the donors the payment is made possible for two years. Sir Humphry Rolleston, in replying to the toast of "The Guests," referred to the change of attitude which was observable in regard to the value of scientific research. It was now recognized, even by the Government, that from a commercial point of view the new knowledge gained by a comparatively small expenditure on investigation by skilled hands might effect great and lasting economies. The recent scientific study of industries and the condition of the workers had been revolutionary in respect of the methods for preventing waste of time and ill health. Organized medical research in the laboratory, he stated, was no less fruitful in furnishing exact results, although systematized clinical research was of equal importance, and, from the complexity of the conditions involved, of greater difficulty. By systematized clinical research alone was it possible to ensure the detection of the earliest signs of disease, and so to facilitate the ideal of medicine—namely, the prevention rather than the cure of disease. Sir Humphry congratulated the city and University of Bristol in having in Dr. Carey Coombs one who was following out both these lines of research in investigating the incidence of rheumatic disease in children; it was appropriate that Bristol, the home of merchant adventurers, should be the home of the Colston Research Society, which endowed and encouraged the search after truth in so many branches of knowledge. The subject of acute rheumatism and its cardiac complications has been brought prominently before the profession during the last few months. A subcommittee of the British Medical Association published a report on rheumatic heart disease in July last, and a second report from the same source appeared in the SUPPLEMENT of April 16th (p. 121), with an appendix prepared by Dr. Reginald Miller on the prevention and control of juvenile rheumatism. In March

last a report on social conditions and acute rheumatism was published by the Medical Research Council, and in an article which appeared in our last issue Dr. Miller compared the reports and summed up the conclusions to be deduced from them.

INTRATRACHEAL INJECTION OF IODIZED OILS.

NEW diagnostic and therapeutic procedures arouse frequently a degree of enthusiasm which carries with it a tendency to overlook or minimize any risks entailed. The unquestioned value of iodized oils in radiography of the chest has led to the adoption of this method of examination on so considerable a scale that the possibility of undesirable effects has been less emphasized than is altogether desirable. Drs. E. Archibald of Montreal and A. L. Brown of San Francisco have, therefore, rendered distinct service by publishing[1] a careful estimation of the dangers of introducing iodized oil into the tracheobronchial system. Although they agree that the practice is, as a rule, safe, they add that, whether the introduction of the oil is transthoracic, transglottic, infraglottic, intercricothyroid, bronchoscopic, or by deglutition, it is possible to cause local sepsis, laryngeal oedema, or a false passage, while excessive quantities of oil may reach the stomach and set up poisoning. Though probably a rare event, infective material from the mouth or larynx may be carried into the alveoli, and the authors have shown by experiment that the presumed antiseptic character of the oil is not to be trusted. The coughing usually caused by introduction of the oil may intensify a pathological process in the lungs, or infect healthy alveoli and induce bronchopneumonia. Respiratory embarrassment may be caused by the oil plugging the smaller bronchi, and this may prevent the entry of air into a considerable portion of the lung with retention and possible absorption of the purulent products. Since it is impossible to regulate the rate or amount of absorption of the oil, the danger of iodism cannot be excluded, and the authors suggest that preliminary determination of the iodine tolerance of the patient would be a useful precaution. In this connexion the possibility of sensitization effects in tuberculous patients must be remembered, since the congestive action of the iodine may light up a quiescent tuberculous process, or cause exacerbation of a chronic mild infection. That these dangers are not hypothetical is shown by reference to the literature and by reports of three cases observed at the Royal Victoria Hospital, Montreal. A man, aged 36, with chronic bronchitis and bronchiectatic dilatations, died after the administration of lipiodol, which provoked an acute pneumonic process. In a woman, aged 27, the introduction of this oil brought about an immediate severe reaction, with rise of temperature and increased pulse rate. In the third case, a woman, aged 28, with quiescent pulmonary tuberculosis, the injection of lipiodol caused a severe febrile reaction, with dyspnoea, cough, and increased expectoration; the exacerbation subsided in a week. Conditions which should be regarded as contra-indicating absolutely the employment of such intratracheal injections are pulmonary tuberculosis, with haemorrhage or pyrexia; suppurative bronchorrhea, with fever; and pulmonary gangrene. It seems clear, therefore, that the introduction of iodized oil into the bronchi should not be employed indiscriminately. The possibility of untoward sequels must be recognized and precautions taken to avoid its use in unsuitable cases.

BOTULISM.

THE tragic episode at Loch Maree in 1922, when eight persons lost their lives through eating sandwiches containing potted wild duck paste, is happily the only authentic instance of botulism recorded in Great Britain. This comparative immunity is in strong contrast wit experience in North America. A recent return shows tha there have been reported in the United States an Canada, from 1899 to 1926, outbreaks to the number c 146, with a total of 496 cases and 329 deaths, givin a case mortality of 66 per cent. During the eight yea 1918 to 1925 there were on an average thirteen outbreak annually. In 1926, the last of the years under notice the number fell to three, in Wyoming, Oregon, an California respectively, all western states. The peccan foods were string beans, trout or salmon, and asparagus all home-canned. The *Bacillus botulinus*, an anaerobi spore-forming organism, is widely distributed in nature It is found in the soil, in dust and, as the casualtie show, in various food stuffs. The frequency of botulis to the west of the Rocky Mountains and especially i Southern California has been ascribed to an abundanc of the spores of the bacillus in the soil of these area The disease, which derived its name originally from it association with sausages, is usually caused by preserve or processed foods, meats for the most part on th European continent. In North America, however, man other articles of diet, such as cheese, spinach, olives, an those above mentioned, have been implicated. Prevention secured by the use of fresh foods, by cleanliness in prepa ing them and by applying sufficient heat to kill the spore Brine or syrup in adequate strength is a safeguard. Aci fruits appear to be guiltless. Thorough cooking tends t protect, but in infected foods the toxin may form again Though only one outbreak of botulism is known to hav occurred in Great Britain, food poisoning accredited t other bacteria such as those of the Salmonella group not uncommon. In England in 1925 there were abou twelve visitations of this kind, one at Plymouth of 30 cases and others at Lynmouth, Clacton, Scunthorpe, Lan beth, Neston, Stepney, Harrogate, Hampstead, and else where. In Scotland during the same year six outbreak were recorded, including a widespread infection Aberdeen involving 497 persons. The total deatl for the year appear to have been two in England and on in Scotland, a different tale from the high mortality c botulism. Botulism in the United States has frequentl followed the eating of home-preserved foods. There a considerable amount of home preserving in this country but the Loch Maree outbreak was caused by a factor product, contained in glass jars. The reporter to th Scottish Board of Health on the outbreak expressed th view at the time that the reputable firms take ever reasonable care and precaution, but said that he woul like to see glass jars abolished, since they do not stan heating to the thermal death point of pathogenic spor so well as metal containers. In order to supply for futur cases, should they occur, such remedy, if any, as may b possible once the signs of poisoning have appeared, an for the protection of persons in the entourage of case who may be presumed to have been exposed to risk, th Scottish Board has caused stocks of antitoxin to be hel available in Fever Hospitals at Aberdeen, Dundee, Edi burgh, and Glasgow for issue as occasion demands.

BLOOD PLASMA AND SENILITY.

IN his Cavendish Lecture at the West London Medico Chirurgical Society on May 27th, Dr. Leonard William epigrammatically remarked that "senescence, like love, i a story which never grows old," and has taken this oppor tunity of touching on some old views in the light o modern research in tissue culture, endocrinology, and s forth. Thus attention is called to Dr. Harry Campbell' insistence twenty years ago on the importance of the bloo plasma, as contrasted with the more easily investigate corpuscles, in the life, health, and disease of the body. A the plasma is built up from the products of digestion an

the internal secretions of the endocrine glands, the tissues, which it bathes and nourishes or poisons, are likely to pay the penalty for dietetic errors and to respond to the stimulus, or remain quiescent in its absence, of the hormones of the ductless glands. On the subject of cookery and food Dr. Leonard Williams follows fairly closely the principles of Metchnikoff, and with a firm but light hand has much to say on "the subtle sins of sloth and gloomy gluttony"; his comment on the treatment of disease, which may result in interference with the saving grace of *vis medicatrix naturae*, gives us the *obiter dictum* that "in comparison with the ordinary British invalid, the forcibly fed Strasbourg goose is an ascetic." Fasting, he points out, is the simplest and safest of remedies in many, especially metabolic, disorders, but, being devoid of mystery, is far from popular. We remember a sanatorium in America the inmates of which were encouraged to eat nothing for weeks at a time. Rejuvenation is, Dr. Leonard Williams said, the motto of the moment, and surgical measures, such as those of Steinach and Voronoff, are much in the limelight, but they should never be needed if moderation in diet punctuated by fasting were universally practised. The lecturer believed Voronoff's reasoning to be sound, and had seen excellent result follow his grafting operation; under the present widespread conditions of overfeeding there were many who might be benefited by the grafting operation, not by the prolongation of life, but by the prevention of senility and the maintenance of efficiency during the duration of life. Sooner or later, of course, and in spite of "laborious days, occasional fasts and grafts," the inevitable stage of the lean and slippered pantaloon arrives, and the final burst of the bubble is probably often brought about by adrenal failure to preserve vascular tone, with the resulting sudden hypotension, as in surgical shock or in collapse, "sometimes fortunately without the surgery."

THE HOSPITAL ALMONER.

A WELL attended meeting, under the auspices of the Institute of Hospital Almoners, was held in London on May 26th, with Lady Bradford in the chair, to inform the public of the work of the hospital almoner, and to stimulate interest in this form of social service. After Dr. Gray had described the functions of the institute, which arranges for the training of candidates as almoners and certifies and registers them, an address was delivered by Sir John Rose Bradford, P.R.C.P., who approached the subject from the point of view of after-care. The need of after-care, he said, loomed constantly in the mind of those who had to do with the treatment of disease. What had for long been recognized as necessary in mental cases was now seen to be no less necessary in physical illness. Working people who had been suffering from rheumatic fever, for instance, were very prone to imagine that immediately after the cessation of any serious symptoms they might resume work under the same conditions as before, and often this meant that the benefit they had received under treatment was undone. In cases of this kind the work of the hospital almoner was particularly valuable, for she was able, with her trained eye, to keep a watch on the patient and to ensure that as far as possible what had been done for him in the way of treatment had its proper chance. Sir Berkeley Moynihan, P.R.C.S., also addressed the gathering, speaking more particularly of the social service department in the hospital from the point of view of the medical staff. He said that those who watched hospital cases over a period of years soon realized that, however brilliant might be the success of the physicians and surgeons in respect to the immediate result, very much remained to be done. Years ago the need was felt in hospital work for somebody who would see that the suggestions and instructions for the after-care of the patient were carried out. Otherwise the efforts made to restore a patient to health or to repair a mechanical defect or deformity never reached their full fruition. This was tantamount to saying that one of the necessary corollaries and completions of surgical work was social service. Since the system of almoners at Leeds Royal Infirmary had been started he had been impressed by the saving of human life and the diminution of misery which had resulted from their constant and devoted work. Not only was the almoner effective in the matter of after-care, but she could do much in the preparation of the patient for effective hospital treatment. Many patients who ought to undergo operation had first of all to be brought back to life before the surgeon could hope to restore them to health. The doctor, the nurse, and the almoner were the tripod on which successful treatment depended. But it was necessary that the almoner should be competent and trained, and should have special gifts for the work. The ideal almoner was a gentlewoman, a person of good breeding and high character, in love with her job, and with a sense of compassion for others. In the north they were finding exactly the kind of gentlewomen needed. At her best the almoner was really the doctor's ambassador on the domestic hearth. Unless every hospital in the future had at least one almoner as a recognized member of its staff, the work done in that hospital would not reach its full effect and would mean a waste of effort and of money. He *himself* at first had been reluctant to admit the almoner into their counsels, but he had come to see that the moment when the surgeon was most delighted with the perfect healing of a wound was the moment at which the almoner should begin her work. The Leeds Infirmary now had five. Sir Arthur Stanley spoke on the value of the social service department in hospital administration, and Sir StClair Thomson wound up with a vote of thanks.

THE MEDICAL MAN IN PARLIAMENT.

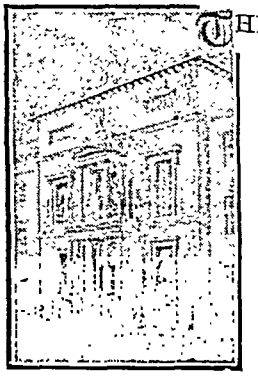
DR. GRAHAM LITTLE, M.P. for the University of London, in an address to the Chelsea Clinical Society on May 31st, lamented that a profession so important to the community as the medical should muster no more than a dozen members in a House of 615. For a medical man to serve in Parliament entailed sacrifice of money and leisure, yet it ought not to be difficult for a man in consulting practice, at all events, to perform his parliamentary duties as efficiently as the practising lawyer, of whom there were about 200 in the House of Commons. Parliamentary proceedings needed very careful watching. A bill of quite considerable effect for large numbers of the community might slip through an almost empty House with practically no discussion. In the case of the Dogs' Protection Bill, had not a small number of members resolute in opposition been present the bill would undoubtedly have gone through in the forty-five minutes available, with disastrous results to medical research in this country. It was not enough to have public agitation outside the House; the position must be secured within the chamber. Medical men were in Parliament by accident. With the exception of a small effort by the British Medical Association, there had been no attempt by medical bodies to secure the parliamentary representation of medicine. The medical profession was freely assailed with the accusation that it was a trade union actuated by sordid motives of self-interest, but it was difficult to imagine any trade union so blind as the medical profession to the importance of taking action where action could be most fruitful—namely, on the floor and in the committee rooms of the House. When he entered the House in 1924 the medical members held an informal dinner and discussed the possibility of forming themselves into a medical group to take corporate action when medical matters were involved. The majority of those present appeared to believe that political differences were too deep to permit of common action from a professional point of view. He

ventured to express an opposite opinion, and suggested that when the group could agree upon a policy that policy should be pursued by common action on the part of the group, but that when there were differences of opinion the group as a group should not act, its members being free to take what course they chose. The group held regular meetings throughout the session, usually fortnightly; it had received deputations from various medical bodies, and two of its members, Sir Richard Luce and himself, acted as unofficial liaison officers between the group and the Medico-Political Committee of the British Medical Association. It had been found possible to present a united front on many professional matters, notwithstanding political differences; three of the group were Labour members, he himself was an Independent, and the others were Conservatives. There were some questions on which the group was divided, and no common action was possible; one of these was the Spahlinger treatment of tuberculosis. Yet considering the smallness of the group it was surprisingly influential, even in a place where so many misconceptions as to medicine prevailed as in the House of Commons, and where the quacks had so many friends. Medical interests arose in many ways. In the present bill proposing to deal with leasehold property there was a clause specifically excluding professional premises from its beneficent operation. He pleaded on the second reading for the inclusion of such premises, and although his speech was limited to three minutes (in deference to the Speaker, whose list of members taking part in the debate was already full) it elicited a promise from the Solicitor-General that he would give the plea most favourable consideration. Amendments had accordingly been tabled whereby the bill would be made to apply to the premises of medical men. With regard to social aspects of the House of Commons, Dr. Little said that the description of it as the best club in London was fully justified. A certain dullness was ineritable in routine business. Nevertheless, the House attracted many interesting figures and outstanding personalities. It was truly said that there was no subject upon which an expert could not be found on the green benches. It was a pleasant unwritten law that every member was upon equality, and titles were dropped, except in the case of the Prime Minister. Outside the chamber party distinctions were forgotten, although in the dining room there were Conservative, Liberal, and Labour tables. There was no rancour, and the friendship among members of different political views was a source of astonishment to visitors from foreign legislatures. Indeed, so attractive was parliamentary life that it was not surprising that those who had once tasted its joys were very loath to relinquish them, and were ready to make astonishing sacrifices of time and money to retain their seats.

PSYCHOLOGY IN GOLF.

PSYCHOLOGY is spreading like star weed. It has invaded the golf courses. The latest example of this is a small volume[1] on mental handicaps in golf, by Dr. T. B. Hyslop, who is not only an enthusiastic golfer, but also an entertaining writer. Before we opened it we felt instinctively that the book would add another to those distractions which afflicted the centipede of fable, and indeed the honorary secretary of the Medical Golfing Society (to whose members Dr. Hyslop dedicates his volume with sympathy and regard) appears to have a similar feeling, for he quotes the whole of the fable in a foreword. Incidentally he quotes it wrongly, but that is another matter. Hitherto we have been under the impression that golfers and poets had one common characteristic in and not made; the golfer, of course, being a wooden spoon in his mouth. But after re Dr. Hyslop has to say on mental handicaps we to the conclusion that a babe with the minimun instincts may grow into a golf champion, p attends to his mental stance, when sufficiently that he is neither too optimistic nor too de addressing the ball, and keeps his mind off hi and his opponent's mind. Moreover, if he s bunkeritis, putterphobia, or any of those othe to which he is subject between the tee and, let the putting green, he need only consult a psyc better still, read Dr. Hyslop's book, which does ever, tell us much in a therapeutic sense. Et diagnosis are its prominent features. Nor is that lends itself to analysis. Its ten short ch concerned with such subjects as prodromata, mental stances, automatism, stigmata of de time-reactions, psychotherapy, the tee-side ma anecdotage. We hoped to enjoy some new golf the last chapter, but it contains none. The oth contain several. The ultimate result of mental is, in the author's own words, that "reserve and reason are the three best clubs for a golfe bag, and these three mental characteristics are triumvirate of potential champions." Altoge a most entertaining volume if not taken too Taken seriously it is distracting and brings us to the fable of the centipede. We note that M name is spelt incorrectly, and we prefer our Colonel Bogey to Dr. Hyslop's Mr. Par.

[1] *Mental Handicaps in Golf.* By Theo. B. Hyslop, M.D., F.R.S.E. With forewords by Rolf Creasy, M.R.C.S., L.R.C.P., and John Henry Taylor. London:



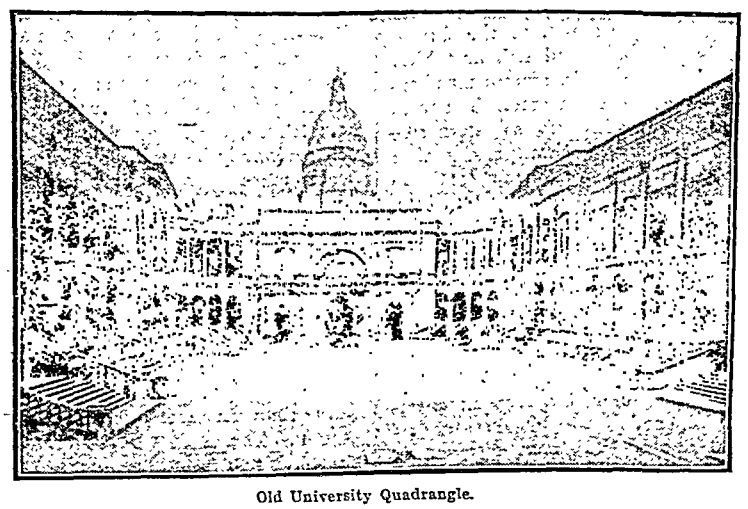
THE BIRTH AND DEATH RATES.

INFLUENZA and the falling birth rate combined a decrease of population in the first quarter of when registered deaths exceeded registered birth in the previous quarter the excess of births o was 43,477. There has not been an excess of d births in any quarter since the March quarte when (owing to the third wave of the great p influenza) the deficit was 47,128. In the last 1918—that is, in the worst phase of the pa influenza—the deficit was 79,379. Although we expect a negative balance to be a frequent re quarterly statement of our vital banking operat near future, the time cannot be very far distant will ordinarily be so little difference between the death rates that much smaller prevalences o disease than that of this spring will lead to a de

THE GENERAL MEDICAL COUNCIL.

THE session of the General Medical Council, wh under the presidency of Sir Donald MacAlister o May 24th, occupied only four days. Although a disciplinary cases were considered, no medical n was erased from the *Register* for misconduct, fewer than six cases judgement was postponed u session. The cases included three in which pract Scotland had been keeping a medical hall or where scheduled poisons had been sold to the an assistant not legally qualified, who, it w was acting under the doctor's "cover." Of disciplinary cases one was concerned with a another with lax certification, and a third with for drunkenness. One case in which the c that of "covering" uncertified women acting a was stopped before the defence was concluded missed. The other business of the Council was

NINETY-FIFTH ANNUAL MEETING
of the
British Medical Association,
EDINBURGH, 1927.



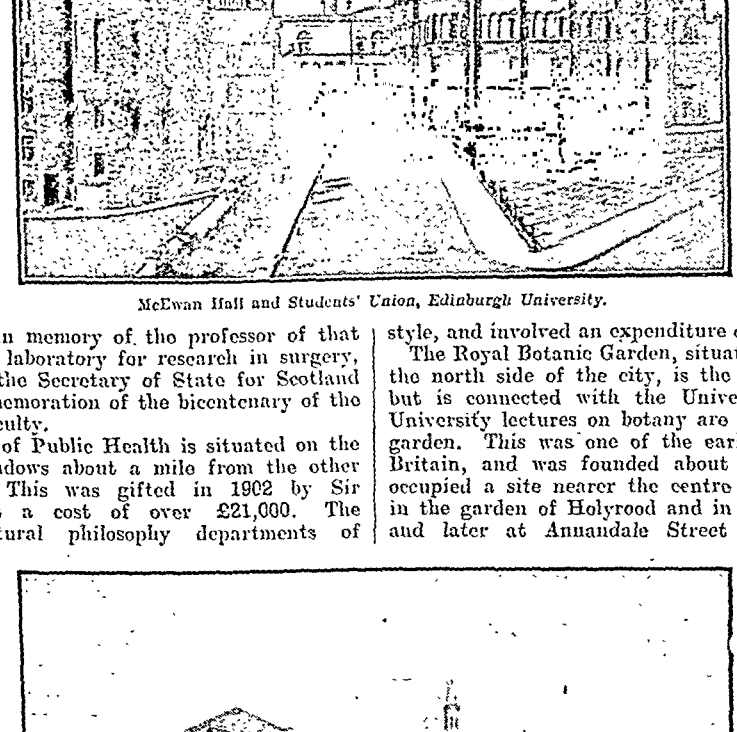
Royal College of Physicians of Edinburgh.

THE ninety-fifth Annual Meeting of the British Medical Association will be held in Edinburg next month under the presidency of Sir Robert Philip, M.D., LL.D., honorary physician to the King in Scotland, who will deliver his address to the Association on the evening Tuesday, July 19th. The scientific and clinical work of the meeting will occupy, as usua the three following days, and on this occasion it will be divided among twenty-one Section The names of the officers of Sections and other preliminary announcements are publishe in the SUPPLEMENT this week; the full programme of scientific business and further detai of the arrangements for the Annual Meeting will appear in later issues. The Annu Representative Meeting, for the transaction of medico-political business, will begin o Friday, July 15th. On the last day of the meeting (Saturday, July 23rd) there will be a excursion to Fife and St. Andrews. We print below the fourth of a series of descriptiv and historical notes on the Scottish metropolis and its relations with the science an practice of medicine. The first article, published on December 4th, 1926, dealt with ol Edinburgh and the beginning of the Medical School; the second, on January 1st, wit the Medical School from 1726 to the middle of the nineteenth century; and the third, o March 26th, with Edinburgh medical institutions.

It has been decided to make the Edinburgh celebrations of the centenary of Lord Lister's birth coincide wit the Annual Meeting of the British Medical Association. A book dedicated to Lister's life and writings is being prepared for the occasion, and throughout the week a museum of Lister relics will be on view in the Upper Library of the old University. On Wednesday, July 20th, at 8 p.m., a public meeting will be held in the McEwan Hall with the Earl of Balfour, K.G., in the chair, when short commemorative addresses will be delivered.

THE UNIVERSITY AND ROYAL COLLEGES AT EDINBURGH.

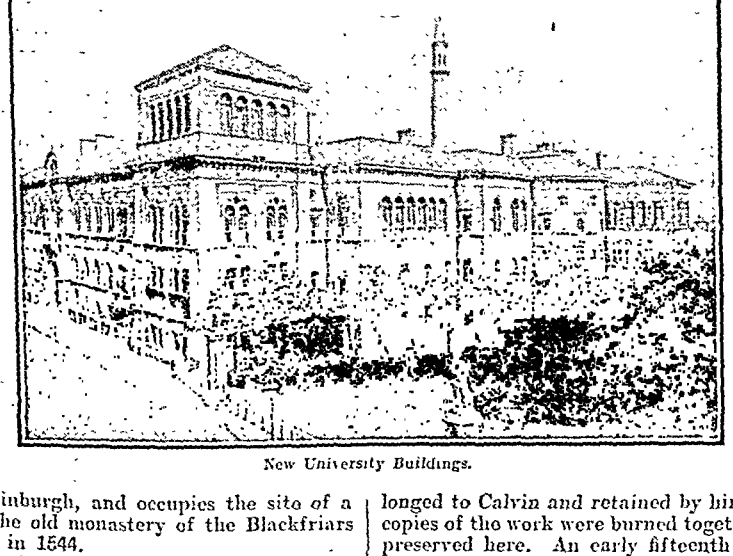
THE University of Edinburgh took its rise in the Town's College, founded by the town council at the instigation of King James VI of Scotland in 1582. The College was at first housed in the buildings of the Kirk o' Field, the scene of the murder of Darnley in 1567. Although these buildings were subsequently renovated, it was found by 1768 that the buildings, "poor in themselves, seem not to have been carried on according to any regular plan, such as takes place in other academical structures which have been erected on more opulent foundations; and hence the whole fabric has a mean, irregular, and contemptible appearance." At this time the number of students was between 600 and 700, and that of the professors 21. A Medical Faculty had been added about the year 1726. A scheme for rebuilding was taken up seriously by the town council, encouraged by the promise of liberal aid from Government, and the foundation stone of the new College, from a plan by Robert Adam, then at the height of his great reputation, was laid on November 16th, 1789. This building, begun on the eastern and northern sides, was greatly delayed by the death of the architect in 1792 and by failure of funds. The remaining two sides of the quadrangle were finished by a Government Commission appointed in 1815, from plans by William Henry Playfair. This work was practically completed in 1828, at a total cost of about £161,000. The building, and especially its façade with monolithic columns 22 feet in height, forms a magnificent example of the work of these two great architects. One of the most striking interior features of the building is the great hall of the Library, 185 feet long with arched ceiling enriched with cassettes. In this hall the British Medical Association is to show a historical exhibition at the time of the July meeting.



Old University Quadrangle.

The present dome, from designs by Sir R. Rowand Anderson, was not completed until 1883, and a war memorial, consisting of five tablets with the names of approximately 1,000 students and alumni of the University who fell in the great war, has been erected under the portico at the western end of the quadrangle.

In 1869 the number of students had risen to 1,500 and that of professors to 33, while there were only 17 classrooms in the University buildings for their use. Extension, therefore, became indispensable, and an appeal was made to the public for subscriptions to provide a new site, and the erection of classrooms, theatres, laboratories, etc., for the Faculty of Medicine. This appeal yielded a sum of



approximately £150,000, to which the Government added a grant of £80,000. The University new buildings situated in Teviot Place were therefore begun in 1878 and opened for teaching purposes in October, 1880. In these buildings the British Medical Association is to hold its meeting in July. The style of architecture is Italian of the Cinquecento period, and is in harmony with the McEwan Hall, gifted by Mr. William McEwan, M.P., and finished in 1857 at a cost of about £115,000. This hall is capable of holding upwards of 2,000 people, and will be used for the Representative Meeting of the British Medical Association, the Lister Centenary Meeting, and various other receptions in July.

McEwan Hall and Students' Union, Edinburgh University.

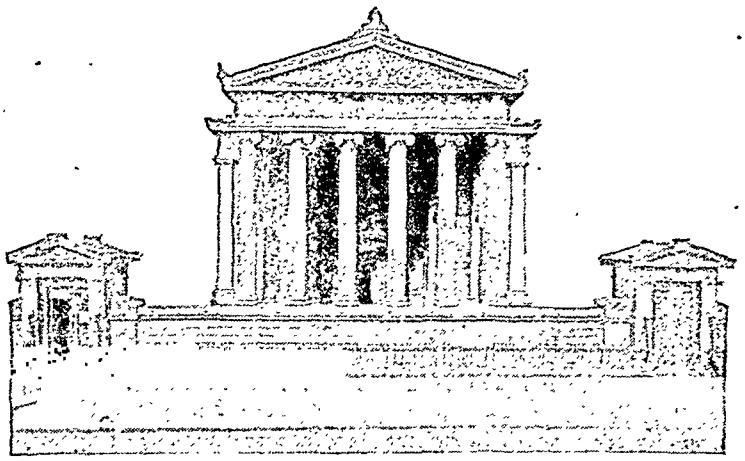
More recent additions to the University new buildings (School of Medicine) have been made in the Hughes Bennett Physiology Laboratory, erected in 1901 in memory of the professor of that name, and in the new laboratory for research in surgery, which was opened by the Secretary of State for Scotland in June, 1926, in commemoration of the bicentenary of the Edinburgh Medical Faculty.

The Usher Institute of Public Health is situated on the south side of the Meadows about a mile from the other University buildings. This was gifted in 1902 by Sir John Usher, Bt., at a cost of over £21,000. The engineering and natural philosophy departments of the University are situated some 200 yards to the east of the old University and occupy buildings of much historic interest in connexion with the Medical School. The natural philosophy building was completed in 1907 by the reconstruction of the old Surgical Hospital, the outer walls being preserved almost without change. The engineering department occupies a building which was previously the part of the old Surgical Hospital in which Lister's wards were situated while he was professor of clinical surgery at Edinburgh. The building was formerly the High School of Edinburgh, and occupies the site of a churchyard adjoining the old monastery of the Blackfriars burned by the English in 1544.

New University Buildings.

Minto House, situated at Nos. 18 and 20, Chambers Street, is used for the University departments of English and Modern Languages, and occupies the site of a mansion originally the town house of the Earls of Minto, which for a time was taken by James Syme as a hospital, where some of his most celebrated operations were performed.

The King's Buildings of the University, situated on the slope of Blackford Hill beyond the southern margin of the city, comprise a range of laboratories which were opened for teaching purposes in October, 1920. These buildi include the department of technical chemistry, the dep ment of geology, and the animal breeding rese department. A considerable extension of these buildi is planned for housing other scientific departments.



The University Union occupies a site in Park Pl close to the McE Hall and adjoin the music classro The Union was stituted in the y 1884, when t Students' Represen tive Council starte movement to col funds for its erecti In 1900 and in 1 extensions were fo necessary to acc modato the increa number of stude Part of the extens occupies the site the famous "H House," to which Walter Scott re in Redgauntlet. buildings form handsome exampl the Scottish baro style, and involved an expenditure of some £41,000.

The Royal Botanic Garden, situated in Inverleith Row the north side of the city, is the property of the Cro but is connected with the University in so far as University lectures on botany are given in the hall of garden. This was one of the earliest botanic gardens Britain, and was founded about 1670, although it t occupied a site nearer the centre of the city, first of in the garden of Holyrood and in that of Trinity Coll and later at Annandale Street near Gayfield Squ whence it was moved to its pres site in 1822-24.

The Univers Library conta about 300,000 volu and some 8,000 ma scripts, of which m are very valua The Library had origin in a collect of some 300 volu bequeathed in 1580 Mr. Clement Litti "Edinburgh and K of God," transfer by the town counci the keeping of University. Am the later collecti are valuable e copies of Shakespe and other Elizabeth writers. One of three copies ext of the Christiani Restitutio of Servet supposed to have longed to Calvin and retained by him when all the availa copies of the work were burned together with their autho preserved here. An early fifteenth century Gaelic medi manuscript and various mediaeval illuminated works also possessed by the Library. Here, too, are some fo busts of former professors in the University.

The Royal College of Physicians, which at the pres day has its Hall at No. 9, Queen Street, was founded 1681, in virtue of a charter obtained from Charles II. College was instituted mainly for the regulation of med practice in Edinburgh and its suburbs, and at an e date (in 1699) it produced a Pharmacopoeia for use

Scotland and about the same time commenced the formation of a library. A new charter, dealing especially with the [illegible] College property and the method of [illegible] and Fellows, was obtained by the College in 1681. Various halls have been occupied by this College. The first was purchased in 1704, and consisted of a house and grounds in Fountain Close in the High Street, adjoining the house of the Marquess of Tweeddale, and the College shortly thereafter purchased a garden extending down to what was then the fashionable street of Cowgate. Permission to walk in the gardens and shrubbery of the physicians was regarded as a privilege by the neighbouring gentry. Here, too, the physicians established a bath, which was open to the inhabitants generally at a charge of twelve shillings Scots, from which the College made a considerable revenue. In 1722 a new hall was erected in the garden, but this proving rather unsatisfactory, the foundation stone of a hall in George Street was laid by Dr. William Cullen in 1776, and the College removed there for the first time in 1781. Finally, in 1846, it removed to the present building. The active part taken by the College of Physicians in the foundation of the Royal Infirmary was described in the BRITISH MEDICAL JOURNAL for March 26th (p. 573) and a somewhat similar patronage was exercised by the College in the foundation at Morningside of the Royal Asylum for the Insane. The library of the College has gradually increased from the time of its foundation, and it possesses a very valuable collection of the works of early medical authors. Many of the manuscript lectures or lecture notes of early teachers in the Edinburgh Medical School are also deposited here. The library now contains about 100,000 volumes. About 1885 a proposal was made to found a laboratory for research, and this laboratory, now situated in Forrest Road, was first opened in 1889. Much valuable scientific work on subjects connected with medicine has been carried out here, and the laboratory is now to a large extent financed by the Carnegie Trust of the Scottish universities. After the passing of the Medical Act of 1858 an important arrangement was made between this College, the Royal College of Surgeons of Edinburgh, and the Glasgow Faculty of Physicians and Surgeons, by which the examinations of the three bodies were to be conducted conjointly, and a triple qualification issued to their licentiates. In addition to the licence the College of Physicians now admits Members and Fellows to its roll.

From a photograph by] [Francis Caird Inglis, Edinburgh.

Royal College of Surgeons of Edinburgh.

The Royal College of Surgeons took its origin from the Guild of Surgeons and Barbers, which received a seal of cause or charter of incorporation from the town council in the year 1505. The activities of this body in its early days have already been described in the BRITISH MEDICAL JOURNAL for December 4th, 1926. One of the chief, as well as one of the earliest, contributions to the establishment of medical study in Scotland was made by this body in the introduction of early anatomical instruction at Edinburgh. Their teacher of anatomy, in the person of Alexander Monro, was taken into the Town's College as professor of anatomy in 1720. For about a century surgery was taught as a part of anatomy in the University of Edinburgh, and the College of Surgeons in 1804 decided that this should be changed. They accordingly appointed one of their Fellows, John Thomson, to be professor of surgery of the Royal College of Surgeons. This was opposed by the University on the plea that a university only might appoint professors, but the College of Surgeons continued their appointment later in the persons of Mr. John William Turner and Mr. John Lizars. Finally, in 1831, the Crown, on the recommendation of the town council, established a chair of systematic surgery within the University. The College of Surgeons also took a part in the foundation of the Royal Infirmary of Edinburgh, although their share in this work was not so great as that of the College of Physicians.

The hall erected for the Incorporation of Surgeons in 1697 is still to be seen, somewhat modified, standing to the east of the physics department of the University. The present handsome building, with a frontage adorned by Ionic columns on Nicolson Street, was opened in 1832. Here are situated the hall with a collection of old portraits, and the examination rooms of the College, together with its museum. This includes, among other things, the anatomical and pathological museum purchased from Sir Charles Bell in 1826. The Guild of Surgeons was erected into a Royal College of Surgeons with new privileges under the Great Seal by George III on May 12th, 1778. In the early part of the nineteenth century the licence of this College was a popular qualification sought in great numbers by men desiring to engage in general practice or to enter one of the services, and after the passing of the Medical Act the Royal College of Surgeons united with the College of Physicians and Faculty of Physicians and Surgeons in Glasgow to grant a triple qualification. The College of Surgeons has also established a licentiateship in dentistry, and grants its Fellowship as a higher diploma obtainable after examination.

England and Wales.

FREEDOM OF HARTLEPOOL FOR DR. W. S. GIBB.

DR. WILLIAM SCOTT GIBB, honorary physician to the Hartlepools Hospital, who has been a member of the Hartlepool Town Council for twenty-seven years, and who was for a period of three years mayor of the borough, was presented on May 24th with the Freedom of Hartlepool. The scroll conveying the Freedom was contained in a silver casket. Dr. Gibb, returning thanks for the gift, regretted the modern tendency on the part of the Legislature to confine legislation to county councils and county borough councils, ignoring small non-county boroughs, which in many instances had long historic traditions. He thought that this policy should be opposed in every possible way, since in many cases economy and greater efficiency would result from such boroughs having control of the expenditure within their own areas. Referring to the influenza epidemic in Hartlepool in 1918, Dr. Gibb pleaded for financial support of research into this infection, in order that medical practitioners in future might be placed in a better position to fight such serious visitations. He mentioned that during the first quarter of the present year the number of deaths had exceeded the number of births; this was mainly attributable to the occurrence of a relatively mild epidemic of influenza in these months.

THE TUBERCULIN DISPENSARY.

The first annual meeting of the Tuberculin Dispensary Benevolent Society, successor to the Tuberculin Dispensary League, was held at the residence of the Earl of Mayo on May 26th. Dr. W. Camac Wilkinson was in the chair.

om the report it appeared that eighty tuberculous tients had been treated with tuberculin at the dispen- ry, 32, Fitzroy Street, during the year, of whom only o had died, one from exophthalmic goitre complicating o disease. Dr. Charles Buttar, in moving the adoption the report, expressed admiration for the coherence in eory and economy in practice of Dr. Camac Wilkinson's ork. Sanatorium treatment seemed to him excessively stly in working, and so incoherent that its advocates ill disagreed whether its main object was to cure early ses or to segregate advanced cases. Dr. Buttar pported the proposal made recently by Dr. Wilkinson the *Times*, that a research institute for tuberculosis ould be established. An address was read by Dr. Camac ilkinson in which he suggested that the recent decline the death rate from tuberculosis was partly due to the ss of 700,000 men in the prime of life during the war. ad they not been killed, probably at least 10 per cent. ould have died of tuberculosis. Dr. Wilkinson pleaded r a fair and judicial trial of every system of treatment hich seemed economically sound and did not demand too reat sacrifices from sufferers from the disease. He urged ie necessity for a five years' trial, under specified condi- ions, of any proposed system of treatment; and asserted hat such trials could only be carried out in an independent nd self-contained institution for the study of tuberculosis. he treasurer, Mr. Randall Davies, mentioned that enerous financial help had been received from Sir Robert IcAlpine, from the Catering Trades Dividing Societies, hrough Mr. F. W. Edwards, and from many others.

THE WELSH NATIONAL MEMORIAL ASSOCIATION.

Spahlinger Treatment.

It has already been reported that at the last quarterly eeting of the Welsh National Memorial Association a eport on the Spahlinger treatment was presented by he Medical Committee. A discussion ensued, but was djourned to a special meeting which has now been held t Shrewsbury. The full text of the report of the Medical ommittee was published in the BRITISH MEDICAL JOURNAL f May 7th (p. 851). It consisted of three parts: in the irst it was recognized that M. Spahlinger had created a odern laboratory at Carouge, near Geneva, and had hown much ability in devising apparatus for special ranches of bacteriology, but that the secrecy maintained s to fundamental details of technique made it almost mpossible to judge the value of his work, while all ttempts to obtain supplies of the Spahlinger prepara- ions for systematic tests by competent authorities had ailed.

In the second part of the report the committee xpressed the view that the remedies obviously did not ffer a "certain" cure for tuberculosis, and that con- lusive evidence had not been forthcoming that they had materially altered the course of the disease. In these circumstances the committee advised the council to maintain the attitude it had adopted on April 23rd, 1926, recommending that as M. Spahlinger had promised supplies of his remedies to the Ministry of Health, which had arranged to make a full investigation (in which the association might probably be asked to participate), it would be well for the association to await the inquiry promised by the Ministry. In the third part of the report the committee stated that it could not recommend the application of public funds towards the Spahlinger Institute, and that the publicity campaign on behalf of the Spahlinger movement was to be deprecated as unjusti- fied by the evidence so far adduced and to be deplored as raising false hopes in the minds of sufferers from tuber- culosis. At the adjourned meeting considerable discussion took place, but eventually the first two parts of the report were adopted unanimously; the third was omitted.

MANCHESTER RADIUM INSTITUTE.

At the annual meeting of the Manchester and District Radium Institute, on May 25th, the possibility of exten- sion was discussed. For some years after the establishment of the Institute in 1915, radium treatment in Manchester was carried on at the Royal Infirmary under a sch elaborated by Sir William Milligan. In the autumn 1921 the work was transferred to a house, furnished a hospital and presented by Sir Edward Holt; an acco of the new facilities thus made available appeared in issue of October 22nd, 1921 (p. 667). Since then work has increased so steadily that the present accom dation has become inadequate. The number of attenda during 1926 was 6,775, an increase of 296 over the prev year. There are only eleven beds in the Institute, a very considerable period of waiting for admissio inevitable in many cases. Sir Edward Holt, speakin the suggested extension, said that the longer treatm now being given rendered the administration of the pital more costly than previously. Sir William Mill supported the proposed public appeal for funds to ex the Institute, in view of the gratifying success that been obtained; many applications for treatment f places outside the Manchester district had to be rejec It was stated that no systematic appeal on behalf of Institute had been made in recent years.

THE ROYAL SUSSEX COUNTY HOSPITAL, BRIGHTON.

Mr. Bernhard Baron has just given £10,000 to Centenary Fund of the Royal Sussex County Hosp The fund was started to increase the accommodation vided, and in particular to add a casualty departm and new buildings for the nursing and domestic s The appeal received the approval of the people of Brig and also of the medical profession there. The institut which was founded in 1826, is the chief general hosp in that part of England, and is held in high esteem by the profession and the public. It contains 225 b and has a special pathological department, establishe a memorial to the late Mr. Stephen Ralli. Many subsc tions were received when the appeal was first made, interest seems to have flagged, and the amount in han not enough to carry out the scheme of the Cente Fund, which includes the addition of sixty extra beds, alternatively, an auxiliary or recovery home for the re tion of a similar number of partially convalescent patie This will involve the provision of bedrooms for more nu and a lecture room; the extension and alteration of operating theatres; the reconstruction and enlargemen the *x*-ray department; the extension of the massage dep ment, with its school for pupils; and the enlargemen the casualty department. The quarters for the ma and resident medical officers are to be enlarged, adequate rooms provided for the domestic staff. Baron has previously made many large contribut to hospitals and kindred institutions; it is hoped that new generous gift of his may stimulate other givers lead to a rapid increase in the Centenary Fund.

Scotland.

MOSQUITOS IN RENFREWSHIRE.

A PETITION of an unusual nature, said to be the firs the kind in Great Britain, was brought before Sh Hamilton at Paisley on May 10th. The local autho of the upper district of the county of Renfrew petitio for the removal of a nuisance alleged to be caused ditches in the district of Muirend, Catheart, which asserted to be breeding-places for mosquitos. Larvae pupae of mosquitos had been obtained in these dit in 1926, and had survived the winter, so that they likely to hatch out in the present summer. Trustees of property affected contend that the existence of mosq does not constitute a nuisance under the Public Health Various expert witnesses, including Professor Ashworth Colonel Glen Liston, Edinburgh, and Dr. MacGregor, med officer of health for Glasgow, have been called, as as a number of residents in the district who had bitten last year by mosquitos. The hearing was expe to last several days.

PROPOSED HOUSING AND HEALTH EXHIBITION IN GLASGOW.

The new Kelvin Hall, Glasgow, is to be formally opened by the King on July 12th, and the corporation is promoting a housing and health exhibition, to be held in the building from September 21st till October 15th. The new Kelvin Hall, on the site of the old hall burned down two years ago, is a fireproof building of ferro-concrete, occupying an area of 240,000 square feet, and will be the largest exhibition hall outside London. The exhibition is to consist of model houses, sanitary appliances, house furnishings, including lighting, heating, and labour-saving devices, appliances for home nursing and welfare, etc. Housing is to be a special feature, and several cottages or bungalows are to be shown fitted with labour-saving appliances.

PURE MILK SUPPLY.

Dr. J. Hume Paterson, medical officer of health for Lanarkshire, gave an address at a meeting in Glasgow of the West of Scotland Division of the National Veterinary Medical Association on May 19th. He gave a short historical sketch of the various Acts, Orders, and Regulations designed to ensure purity of the milk supply. The Special Designations Order had been, he said, the greatest advance that had taken place during recent years in this matter, as it had both raised the chemical standard of milk and had ensured cleanliness by establishing a standard for bacteria, which he believed was the only reliable standard for invisible dirt. In the county of Lanark at the present moment the licences held for supplying the various grades of milk numbered: certified milk, 13; Grade A (T.T.), 19; Grade A, 4; and pasteurized milk, 1. An additional safeguard would be furnished by having composite samples of milk from a Grade A herd examined at intervals of, say, three months for the presence of tubercle bacilli. If any were found, the veterinary inspector should then examine the herd to find the offending animal. Pasteurized milk, Dr. Paterson thought, should be abolished, because pasteurization was no guarantee that clean milk was being supplied, since no standard was set for the original milk before it was pasteurized. He suggested that the grades of milk should not be more than two—namely certified milk and Grade A milk.

ABERDEEN STUDENTS' HOSPITAL COLLECTION.

As a result of the recent hospital gala week in Aberdeen the sum of £5,577 has been distributed by Aberdeen University students to the Aberdeen Royal Infirmary and other hospitals in the city. The sum collected was an increase of £857 over last year's total. During the past eight years the students, by these annual gala weeks, have raised nearly £33,000 for the hospitals of the city. The allocation of the money collected this year was as follows: Aberdeen Royal Infirmary £3,323, Maternity Hospital £1,200, Aberdeen Royal Hospital for Sick Children £800, Aberdeen Eye Institution £100, District Nursing Association £100; carried forward to next year, £54.

Ireland.

PRIVATE PATIENTS IN COUNTY HOSPITALS.

THE County Wexford Health Board received recently a medical deputation with reference to the question of fixing the terms of remuneration of Dr. O'Brien, surgeon to the County Hospital. The deputation consisted of Dr. T. Hennessy, Irish Medical Secretary; Dr. W. W. Murphy (Coolgreany) secretary of the County Wexford Medical Association; Dr. W. C. Lawler (Bunclody); Dr. G. A. Hickey (New Ross), and Dr. O'Brien, County Hospital. Dr. Clinch, Inspector of the Local Government Department, was also present. Dr. Hennessy said the whole question in dispute between the Health Board and Dr. O'Brien was whether he should be allowed to charge for private patients. From the legal aspect, only patients of a certain class were entitled to hospital treatment; they corresponded approximately with those entitled to free treatment in the dispensary. The idea in the scher of treating private patients in the county hospitals w partly to benefit the local ratepayers and partly to suppl ment the inadequate official salary of the county hospit surgeon. The medical profession as a body never look too favourably on the arrangement, but they did not de the boon it would be to the local ratepayers, especially tho with limited means, to be treated in the local hospital. I could quite understand that a Wexford farmer who cou have an operation done in Wexford for £25 or £30 wou be getting a great boon, because if he went to Dublin would possibly cost him £100, as he might be six or seve weeks in a home at a charge of eight to ten guineas week and have to pay medical fees besides. By having th operations in Wexford means would be afforded to th surgeon to supplement what would generally be admitted t be an inadequate salary. The county surgeon (Dr. O'Brie had an official salary of £500 a year. The district justic had £1,200 a year. He thought a good operating surgeo should be as great an asset to the county as a leg administrator such as a district justice. There was, D Hennessy said, a proposal to give Dr. O'Brien an inclusiv salary, to treat both Poor Law patients and privat patients. That would not be sanctioned by the Loca Government Department. An inclusive salary was out o the question. The cost of medical treatment of privat patients must be entirely an arrangement between ther and the hospital surgeon, as in the case of private medica practitioners and their private patients outside th hospital. Dr. Clinch, Inspector of the Local Governmen Department, explained the attitude of that departmen with regard to the draft regulations which it drew up t govern the admission of paying patients to county healt board hospitals. He also informed the board that the Local Government Department would not sanction a salary for the surgeon of the county hospital to include fees which should be alone chargeable to his private patients, as to do so would be an injustice to the ratepayers and to the profession. After a long discussion, the whole matter was, on the suggestion of the chairman, adjourned to the next meeting, pending a reply from the department about the draft regulations made at a special meeting of the Board in Wexford on April 23rd. The chief provision was to admit paying patients at 9s. a day in private wards and 6s. a day in semi-private wards, with appropriate charges in addition for any special nursing, medical fees, or other expenses. The surgeon would be required under the proposed regulations to treat all patients admitted to the hospital, and in consideration of these services the Health Board would pay him £300 per annum in addition to his present salary of £500 with allowances. It was also provided that the surgeon should, if the patient required it, permit any other doctor to have access to the patient, and should, as far as possible, act in consultation with such doctor. If a patient was refused admission by the county surgeon, or the matron in his absence, a report should be furnished at the next meeting of the Health Board on the reasons for such refusal.

NOTIFICATION OF TUBERCULOSIS.

A memorandum dealing with the notification of tuberculosis has been sent to each sanitary authority in Northern Ireland by the Ministry of Home Affairs. The memorandum states that it is the duty of any medical practitioner attending on any person within a district in which part of the Tuberculosis Prevention (1) Act, 1908, has been adopted, on becoming aware that such person is suffering in any prescribed circumstances from tuberculosis of any prescribed form or at any prescribed stage, within seven days after he becomes aware of the fact, to send to the medical officer of health a certificate in regard to the case. Under section 1 (4) of the same Act it is enacted that a medical practitioner who fails to send the certificate within the period specified shall be liable on summary conviction to a penalty not exceeding 40s.

ULSTER MEDICAL SOCIETY.

The annual meeting of the society was held in the Medical Institute, Belfast, on May 24th; Dr. Loughridge, vice-president, occupied the chair. The reports from the

honorary secretary and treasurer, and librarian, were received and adopted; 197 Fellows and 58 members had now joined; the statement of accounts showed a balance of £589 to the credit—this balance would be reduced by about £300 before the winter session by the purchase of an epidiascope. Dr. Calwell raised the question of reduction of the annual subscription with the object of increasing the number of Fellows and members, but it was considered advisable to postpone its consideration. Professor Thomson proposed that a small committee should be appointed to discuss with the Library Committee of the Queen's University the possibility of coming to some agreement to avoid the duplication of periodicals; this was agreed to, and the officials of the society, with Sir Thomas Houston, Professor Fullerton, Mr. Craig, Mr. Crymble, and Professor Lowry, with Professor Thomson as chairman and convener, were appointed. The following officers were elected: President, Dr. J. C. Rankin, Belfast; Ex-president, Dr. J. Nolan, Downpatrick; Vice-presidents, Mr. Henry Hanna, Belfast, and Mr. T. Killen, Larne; Council, Drs. Loughridge, Burns, Mr. Crymble, Drs. Marshall, O'Flaherty, and Peatt; Honorary Treasurer, Dr. J. T. Lewis; Honorary Secretary, Dr. R. M. Beath; Honorary Editorial Secretary, Dr. J. A. Smyth; Honorary Librarian, Dr. W. L. Storey.

Correspondence.

DRUGS FOR SLEEPLESSNESS.

SIR,—"*And what he greatly thought, he nobly dared.*" I and many other alienists will rejoice to see that Sir Maurice Craig has "dared to be a Daniel" on the question of sedatives in early mental diseases.

We live in a world of inconsistencies and paradoxes. The doctor who gives a dose of medicine which relieves agonizing physical pain is thought "thrice blessed" by the grateful patient, while in many cases the alienist who attempts to relieve mental pain and anguishing sleeplessness is said to be "drugging" the patient or "promoting a drug habit." Hilton taught us what was meant by relief of physical pain, while my old friend and teacher, Maudsley, impressed upon all how necessary it was to give relief to mental suffering. Many an early case of melancholia has been quickly cured by recognizing this necessity. I wish Sir Maurice Craig had not confined himself to the barbitone group of drugs, though their usefulness is known to all alienists. Sleeplessness must be often combated by more scientific therapeutics than reliance on any one class of drug. Idiosyncrasies have to be studied, the state of the circulation has to be gauged.

For insomnia with a high blood pressure there is no drug so useful as chloral, while in patients with a low blood pressure some drug of a stimulating character like opium, either in the form of Batley's solution or nepenthe, must be our sheet anchor. In many cases, however, in which neither of these extremes is met with, I think of all this group medinal is the best.

Much might be written on this subject of the necessity for drugs in cases of insomnia and of the many varieties of such drugs. My constant rule has been to give such drugs into the safe keeping of a second person, and during my fifty years of practice I have never had a case of "drug habit" developed by the use of any drug I have ordered, and many cases have been able, once the sleep habit has been established, to leave off the drug immediately with no ill effect.

I trust other alienists will come forward to help all those who believe sleep and relief from mental pain are necessities if hope of early recovery in mental disease is to be an accomplished fact.—I am, etc.,

Bournemouth, May 29th. LIONEL A. WEATHERLY, M.D.

SIR,—On May 10th, 1927, at the annual meeting of the Section of Therapeutics and Pharmacology of the Royal Society of Medicine papers were read by Dr. F. A. Pickworth, Dr. Helen Young, and myself on the clinical and pathological effects of hypnotic drugs of the barbituric acid and sulphonal groups. The meeting was well attended and representative of those engaged in the teac pharmacology—Professor Gunn of Oxford, Professo Dixon from Cambridge, Dr. P. Hamill, and many were present. A full discussion followed the pap general agreement was expressed with the con arrived at.

It is unfortunate that Sir Maurice Craig did not the meeting and take part in the debate, for I f the most suitable place for a critical discussion subject would have been the meeting at which the were read. It is, I fear, trespassing somewhat on your generosity and your valuable space by spondence which would more appropriately have part of the Society's discussion.

It may be added that my paper has not y published in the *Transactions* of the Royal Soc Medicine, so that the criticism of Sir Maurice somewhat premature.

Since the introduction of the barbituric acid con (from 1906 to 1925 inclusive) no fewer than 253 from poisoning by these drugs have been recorded Registrar-General's statistics for England and Wa 1925 there were twenty-two deaths. These figure means express the actual number of fatal cases, Registrar-General's returns contain, in addition, of deaths due to narcotic poisoning, "kind not some of which were doubtless due to barbitu compounds. In addition, as pointed out in my pa veronal compounds in large doses commonly cau and bronchopneumonia, and some deaths from poisoning are undoubtedly certified as pneumonia.

I personally saw a number of the fatal cases of po and in a large proportion of these found that the possessed a medical prescription and had been tak drug over a long period. There was often clear of addiction to the drug. As a result of this ad together with the consequent mental depression, a la fatal overdose had been taken. Very many of the were in persons of education and in the prime of li

When fatal poisoning occurs the physician who h the prescription is not usually called in to deal grave emergency, and in all probability never hear fatal consequences. Are the frequent deaths from ing by veronal, medinal, and their allies to be brushed aside as of no consequence?

My clinical experience of a large number of thes cases compels me to raise my voice against the pra prescribing these drugs over long periods and of patients to believe that they are harmless. To quot cases:

On February 21st, 1921, a married woman, who had tak 5 grain medinal powders, was seen by me. This patient taking a *daily dose of 5 grains of medinal over a long p* the prescription of an eminent physician. This culminate taking forty powders at once with fatal result.

On April 29th, 1921, I saw an unmarried woman who one year been taking 10 grains of veronal every night on prescription. This caused mental depression, leading her 10 ounces of pure lysol with fatal result.

On November 25th, 1924, I saw a married woman sufferi veronal poisoning and consequent pneumonia, which te fatally. A very large dose had been taken and a similar of the taking of veronal on medical prescription over period was obtained.

On February 22nd, 1927, I saw a man suffering from poisoning and consequent pneumonia. This patient had the habit of taking veronal on medical prescription nightl long period. He then took a large and fatal overdose.

I have notes of many other similar cases.

I do not question that it is safe for so ex physician as Sir Maurice Craig to prescribe ver medinal over long periods to patients under his co personal observation, but to give a patient a pres for prolonged use when not under continued skilled observation is, I unhesitatingly say, a dangerous pr

Addiction to the barbituric acid compounds undo occurs, and is a real danger. I have personally see cases of marked addiction. The literature on the has been carefully collected by Dr. Helen Young, the references are at the disposal of Sir Maurice The evidence from this is overwhelming.

In 1912 a fatal case of veronal poisoning in a young man was investigated by the Director of Public Prosecutions in conjunction with the coroner. I have before me the deposition of the distressed mother, which states:

"I knew he took veronal for years; I implored him to give it up, but he said he could not. . . . He took it first for pneumonia and never could give it up. . . . He had been taking veronal for six years. . . . He told me he should never be able to give it up. . . . He seemed to lose all self-control when he wanted it. . . . Apart from that he was mentally all right."

What stronger evidence of veronal addiction could one have than that?

Addiction is only discovered when the drug is withheld. If Sir Maurice Craig advocates the taking of veronal and medinal daily over long periods I can readily understand how he does not discover when his patients have in fact developed addiction.

Sir Maurice Craig expresses the opinion that addiction to barbituric acid compounds is "practically non-existent," and then goes on to quote two classes of persons who might become addicts, the chief being the degenerate type. Such a statement is in direct contradiction to my clinical experience. Even a perfectly normal person, if exposed to the continued action of veronal and its allies in moderate doses over long periods, runs a grave risk of becoming an addict to the drug.

The late Sir Frederick Mott was deeply interested in the pathological effects of the barbituric acid group of drugs, and in conjunction with Dr. Pickworth and Mr. D. L. Woodhouse, M.Sc., carried out during the last two years of his life a research into this subject. The pathological evidence from this research, which was published in the *British Journal of Experimental Pathology* in 1926, shows conclusively that organic changes are caused in the central nervous system by the continued taking of such drugs, and that when the drugs are discontinued these changes gradually clear up.

Clinical evidence supports this research. I have on many occasions seen definite objective nervous symptoms, such as ataxic gait, diplopia, anarthria, paralyses, etc., result from the continued daily administration of a veronal compound in a therapeutic dose.

On November 27th, 1926, I saw a patient suffering from ataxic gait, diplopia, and defective articulation. This patient had been taking a full dose of allonal daily for six weeks. On December 25th, 1926, I saw a patient suffering from ataxia, drowsiness, diplopia, and thick speech. In this case veronal was found in the urine and cerebro-spinal fluid. In both of these cases the symptoms completely cleared up on discontinuance of the drug. Sir James Purves-Stewart saw these two cases in consultation with me, and I have his permission to state his entire agreement with the diagnosis of poisoning by barbituric acid compounds.

The occurrence of definite objective nervous symptoms following the continued use of these drugs in therapeutic doses is a strong reason for the exercise of caution in their use.

I am compelled to express my conviction that to advocate the daily use of the barbituric acid compounds over a long period, unless the patient is under continued skilled medical supervision, is misleading to the medical profession, dangerous to the public, and, above all, highly dangerous to the patient.—I am, etc.,

W. H. WILLCOX.

London, W.1, May 31st.

SIR,—In regard to the letter from Sir Maurice Craig published in your issue of May 28th (p. 983) it may be of interest to state that I have had a patient who suffered for many years from paranoia of the persecutory type. This woman had taken medinal on the advice of a mental specialist almost continually for twenty years, and finally such was her mental deterioration that she committed suicide by taking the contents of forty powders of 5 grains each. The mental deterioration may, of course, have been due partially or wholly to the normal trend of the pathological condition, but the medinal had apparently no beneficial effect.—I am, etc.,

London, N.W.11, May 28th. L. S. WOOLF.

RHEUMATIC INFECTION IN CHILDREN.

SIR,—My first duty in replying to Dr. Miller's rejoinder (May 21st, p. 937) to my letter published on May 7th (p. 854) is to thank him for his gracious acknowledgement of the work done at Glasgow in connexion with the rheumatic child.

I can now see that all the difference between the subcommittee's idea of a "rheumatism supervisory centre" and a "cardiac clinic," so-called, is one of name, as the objects seem to be identical, and Dr. Miller admits that he intends treating all types of the rheumatic infection, that medicinal treatment will be given, and that cases will be referred to the wards or to the various special clinics (dental and laryngological) if necessary, and I suppose also for residence in the country if such can be arranged. These, as Dr. Miller knows, are just the very facilities which we provide in Glasgow. I don't suppose anyone has ever been so rash as to suggest the setting up of a special clinic complete in itself with beds and dental, laryngological departments, etc.

I think it is perhaps a pity that "the subcommittee did not consider such matters as the classification of cases." Though this may at first sight seem a somewhat subsidiary matter, I can assure Dr. Miller that it is one of great importance for the welfare of the clinic. The necessity for accurate classification calls for the most serious consideration of the case, so that the patient will in all probability be more carefully examined. From a satisfactory classification, too, it is possible easily to analyse the results obtained in any one clinic, and, if a uniform classification were adopted, the findings of the different clinics would be readily comparable.—I am, etc.,

Glasgow, May 25th. LEONARD FINDLAY.

THE CONSTITUTIONAL FACTOR IN DISEASE.

SIR,—I cannot understand why Dr. Chalmers Watson, in his letter to the JOURNAL of May 28th (p. 984), should assume that I base my recommendation for giving hydrochloric acid to those relatives of patients with Addison's anaemia and subacute combined degeneration of the cord who are found to have achylia gastrica, as a prophylactic against the disease, on the fact that 4 out of 100 healthy medical students had achlorhydria. I gave my reasons in my address on the constitutional factor in disease, but as he has misunderstood me, I hope I may be forgiven for repeating them.

(1) Addison's anaemia and subacute combined degeneration are always, or almost always, associated from their earliest stages with achlorhydria.

(2) Achlorhydria probably always precedes the development of A.A. and S.C.D.; it has been actually known to exist between one and twenty-five years before the first symptoms in 22 recorded cases.

(3) A.A. and S.C.D. are often familial, and as many as six members of a family have been affected; it was so in 28 per cent. of my private cases, and a family history has been recorded in at least 65 cases by other authors.

(4) Achlorhydria is often familial. Moreover, Addison's anaemia occurred in one or more members of the family of six patients of mine with achlorhydria suffering from various conditions, who were found to have a normal blood picture and a normal nervous system, and twenty-six similar family histories have been recorded by others.

As achylia gastrica is a constitutional and familial condition, which may lead to the development of Addison's anaemia and subacute combined degeneration of the cord in one or more members of a family, it seems reasonable to try to discover its presence before it has led to any ill result, as by giving hydrochloric acid we may hope to prevent the development of the very serious diseases which constitute the A.A.-S.C.D. syndrome, as well as the various digestive and general disorders to which it predisposes.

I wish Dr. Chalmers Watson would give us details of the investigations which have taught him that migraine is due to an alimentary toxaemia. We have never found any abnormality by means of test meals, microscopical, chemical, and bacteriological examinations of the stools and urine,

radiological examinations of the alimentary tract, the laevulose test for hepatic efficiency, estimation of blood sugar, urea, and uric acid, blood counts, and cutaneous tests for protein sensitization.—I am, etc.,

ARTHUR F. HURST.

New Lodge Clinic, Windsor Forest, May 30th.

CATARRHAL VACCINES.

SIR,—The letter from Dr. L. R. Lempriere, medical officer of Haileybury College, in your issue of April 2nd (p. 642) is a valuable contribution to our knowledge of this subject, and it is to be hoped that statistics on similar lines will be worked out elsewhere.

Unlike Haileybury, the medical interest in Eton College is divided, and it is not at present proposed to issue detailed statistics of the results of prophylactic vaccines for the school as a whole. The following figures, which I have worked out for a small section of the school, may, however, be of interest. They refer to boys in three of the houses. In almost every case the inoculated boys had three injections of the St. Mary's Hospital anticatarrh vaccine (supplied by Messrs. Parke, Davis and Co.) during the summer holidays or at the beginning of the Michaelmas term. There were no serious complications in this series.

	Inoculated Group.	Uninoculated Group.
Number investigated	26	54
[illegible] on account	9	28
... ...	34.6%	51.8%
Total number of working days lost	64	257
Average number of days lost per head of each	2.5	4.8
[illegible] of those	7.1	9.2

The numbers involved are too small to form the basis of any final conclusions, but so far as they go agree with Dr. Lempriere's figures as indicating a slight but definite advantage in favour of inoculation. So far as this section of the school was concerned the inoculated boy was less likely to be taken ill, and if he were taken ill was likely to be ill for a slightly shorter time than the uninoculated boy.

The value of inoculation may, however, in certain circumstances, be much greater than these figures suggest, for the following reasons:

1. In this series the decision whether or not a boy should be inoculated rested entirely with the parents, with the result that those boys who were known to be particularly prone to colds and influenza, or were regarded by their parents as being delicate, fell mostly in the inoculated group, while those who were least susceptible and gave their parents least anxiety on grounds of health fell mostly in the uninoculated group. A better comparison for statistical purposes would be obtained if all the members of certain houses consented to be inoculated, while all the members of other houses refrained from inoculation. The two groups would then be roughly comparable as regards susceptibility.

2. The inoculations were made in or about September, whereas none of these boys in either group fell sick with influenza or feverish colds till four or five months later, when the effect of the inoculations must have largely worn off. If the epidemic had occurred in the Michaelmas term instead of the Lent term, or if the inoculations had been made in the Christmas holidays instead of the summer holidays, the advantage to the inoculated would presumably have been very much more marked. There is much to be said in favour of maintaining the immunity of susceptible individuals by giving them supplementary injections once a month throughout the winter season.

3. Anticatarrh vaccines are at least as likely to help the ordinary non-febrile catarrhal rhinitis and bronchitis, or to curtail the catarrhal stages which follow a feverish attack, as they are to help the feverish cold or influenza. But in so far as the merely unpleasant afebrile catarrhal stages are not often sufficiently serious to keep a bo out of school, the advantage of the vaccine in preventin or shortening these stages does not appear in the abov figures.

4. The value of inoculation is least evident where onl a small proportion of individuals is inoculated (as in th present instance), and would be most evident where all th individuals of a community were protected. For in th latter case each individual would reap the benefit o inoculation in two different ways: his immunity would b raised in virtue of his own inoculation, and his chanc of infection would be lowered by reason of the inoculatio of the others.—I am, etc.,

Eton, May 30th. NORMAN A. SPROTT.

BIOLOGY AND MEDICINE.

SIR,—In his address on biology and medicine (May 21s p. 909) Dr. Haldane, after exposing the futility of vitalism points out clearly that "the mechanistic conception of li is inadequate in physiology and morphology. For the san fundamental reasons it is inadequate in Medicine, and i pathology, pharmacology, and therapeutics." He adop a middle course by accepting the "Hippocratic conceptio of life as a struggle in Nature against chaos." Since n man knows better than he that "in the process o clearing our minds controversy is unavoidable," he wi forgive me when I pit my opinions against his.

Every thinking human being must be troubled with th difficulties ably set forth by Dr. Haldane. We must s realize the impossibility of vitalism on the one hand an materialism on the other. But I venture to think tha Dr. Haldane, in his desire to find the way for us out o our difficulties, has added to them in two ways. H has emphasized the differences between organisms an inorganic nature at the expense of their correspondence and has raised an unnecessary difficulty when he compare the orderliness of "life" with the chaos of the rest o the universe. But are there signs of chaos? Is not th simplest chemical formula the expression of order, an would it be possible to write it down if it were not? Wh does $H_2+O=H_2O$? For two reasons. Because of th inherited normal structure of the H and O atoms—I us the adjective advisedly—and because of the orderly actio of the environment, the action of an appropriate stimul and the presence of an auxetic, catalyst, ferment, or wha ever we like to call it—namely, a trace of moisture. Ther is no chaos here, but cosmos, normality, law, order, an necessity. There is more: a true expression of what w call "life" in its simplest and most rudimentary form And once the molecule of H_2O is formed it functions as whole, and its functions are very different from those o H and O. It keeps its normal composition—its indiv duality—as long as it can, as long as its environmen permits. The most highly developed organism achieve little, if anything, more. Everywhere there is a per petual reaction to, or struggle against, the environment as is shown by pathology, medicine, and therapeutics.

Is not the realization that vitalism and materialism ar synonymous the only way out of our difficulties? The on emphasizes function, the other structure; the inseparabl aspects of a duality present alike in organic and inorgani Nature the expressions of its very essence or "life."— I am, etc.,

Guy's Hospital, S.E., May 24th. G. W. NICHOLSON.

THE DIAGNOSIS OF GANGRENE OF THE SMALL INTESTINE.

SIR,—In the BRITISH MEDICAL JOURNAL of May 7t (p. 836) Dr. B. W. Rycroft gives a most interestin account of a case of embolism of the superior mesenteri artery, in which, "puzzled by the combination of faeca vomiting, indicating bowel obstruction, and continuou [? "continued"—A.E.R.] passage of flatus, indicatin bowel patency," he "made a tentative diagnosis of partia intestinal obstruction"—a very good and logical one, i may be allowed. He thinks that "the combination o faecal vomiting with persistent passage of flatus mus surely be unique," and suggests that "the combination o

persistent faecal vomiting with the continued passage of flatus is so rare as to be pathognomonic of the condition of intestinal stasis due to gangrene of the small bowel following on deprivation of blood supply."

But his own diagnosis of partial intestinal obstruction includes the possibility of a Richter's hernia, in speaking of which Rose and Carless say that "if less than half the circumference of the bowel is constricted, the obstruction is not always complete at first, flatus and faeces being sometimes passed; but where more than half the circumference of the bowel is engaged, complete obstruction from kinking or paralysis of the gut ensues. The vomiting is less marked than in other cases, and is not so commonly faeculent."

"Faeculent," by the way, or "stercoraceous," is a more accurate term than "faecal" to describe the vomiting of intestinal obstruction, the word "faecal," though frequently used loosely, being better restricted to the description of the vomited matter in cases of gastro-colic fistula, in which true faecal masses may be ejected.

Richter's hernia, then, even according to the textbooks, is a condition in which the symptom of faeculent vomiting may be associated with the ability to pass flatus; and in this connexion may be mentioned the case of a man admitted to St. Bartholomew's Hospital on May 16th with a Richter's hernia of five days' duration, who vomited faeculent material (not for the first time) on arrival at hospital, and whose abdomen showed typically the characteristic ladder-pattern of small intestine obstruction, though it was only very slightly distended, owing to his continued, but impaired, ability to pass flatus—these symptoms, in conjunction with the presence of a tense tender swelling of the size of a cherry in the position of a right femoral hernia, enabling the diagnosis of a Richter's hernia to be made. Operation verified this, and showed that about two-thirds of the bowel circumference were involved. The gut was deep purple, and did not regain its normal colour on releasing the constriction; but it bled when pricked, and so far its reposition in the peritoneal cavity has been justified by the event.

The answer, then, to Dr. Rycroft is that the association of faeculent vomiting with continued ability to pass flatus is highly suggestive of partial intestinal obstruction (such a combination might also conceivably occur in peritonitis without a mechanical block), but is not "pathognomonic of gangrene of the small bowel following on deprivation of blood supply," the question of the occurrence of gangrene being irrelevant. Gangrene was not present in the case just described.—I am, etc.,

ALEX. E. ROCHE, M.D., M.Ch., F.R.C.S.,
Chief Assistant to a Surgical Unit, St. Bartholomew's Hospital.

May 21st.

SIR,—The account in your issue of May 7th (p. 836) of a case of gangrene of the small intestine prompts me to publish some notes which I once compiled on a similar case.

A man of 55, who had never had a day's illness in his life, was, after a preliminary feeling of nausea, suddenly overcome by an agonizing and persistent pain in the abdomen. He was removed next day to hospital, where I saw him. His appearance and his outcry were painful to witness, to such a degree that I felt I was confronted with a functional case. He sat bolt upright in bed, jealously guarding his abdomen from any contact, and shifting his position very gingerly from time to time. At intervals of about ten minutes, punctuated by sonorous eructations, he vomited some bilious fluid. His temperature was normal, his pulse rate 90 per minute. The pain was continuous and localized to the right of the navel. I was able to feel his abdomen only after an opiate had been given. There was neither rigidity nor distension, and nothing abnormal to be felt. The percussion note was dull in both flanks and tympanitic in front. The bowels were constipated, but were moved by an enema, an ordinary motion resulting, free from blood or slime. Some flatus was passed with this motion, but at no other time. The tongue was clean.

Next morning, when the effects of morphine had faded, his symptoms were renewed with zest. The temperature remained normal, but the pulse rate had risen to 120 per minute. Another enema was returned clear. There was a vague swelling, dull on percussion, over the painful area. Distension was still absent, and rigidity of the abdominal muscles was not marked. The vomit was bilious and not faecal. He was seen by Dr. Allan of Barrow-in-Furness, who diagnosed acute intestinal obstruction, with reservations as to the cause.

At operation, forty-eight hours after the onset, a copious blood-stained fluid welled out of the abdomen. Near the lower end of the ileum a segment of bowel, six inches long, was found, dull, indurated, and of a deep purple colour. The corresponding wedge of mesentery was deeply congested. Clamps were applied well to either side of this segment and a yard of gut was resected, together with its mesentery, right down to the root. Side-by-side anastomosis was done and the abdomen closed.

The pain persisted, apparently undiminished, for twenty-four hours after the operation. Turpentine enemata and pituitrin were given, and soon the bowels were moving spontaneously. Three days after operation a faecal fistula developed, but closed in less than a month. The man was discharged well, two months after admission. A year later he was in robust health and engaged in arduous labour.

From examination of the specimen the case was considered to be one of mesenteric thrombosis. Physical examination of the patient afforded no clue to the predisposing cause.

The delay in correct diagnosis arose through a certain resemblance to an attack of tabetic crisis. This was supported by the presence of very small and sluggish pupils, the failure to elicit knee-jerks, and the almost hysterical behaviour of the patient. The small amount of flatus passed may have been introduced with the enema.

The chief difficulty encountered at operation was that of determining the limits of the infarct. Even at a distance of a foot from the edges of the congested piece of bowel devascularization was apparent, and the occurrence of the faecal fistula can only be explained by the inclusion of unhealthy bowel in the stump.

References in literature to this condition are surprisingly rare, and such as do exist show a distinct variety in the clinical pictures that they present. In some instances intestinal obstruction has only been vaguely suggested. A constant factor is the prognosis, which, with or without operation, is sinister in the extreme. If untreated, the condition is fatal, after a period varying from three days to three weeks. The operation mortality is 85 per cent.

I have the kind permission of Dr. Allan, honorary surgeon to the North Lonsdale Hospital, Barrow-in-Furness, to make this publication.—I am, etc.,

A. LYLE GALBRAITH, M.B., Ch.B.

Worcester, May 29th.

ROOT TUBERCULOSIS IN CHILDREN.

SIR,—In the review of our book *Tuberculosis of the Lungs* in your issue of May 21st (p. 922), your reviewer condemns as wholly unjustifiable the inference we have drawn from a somewhat extended experience that in most cases of root tuberculosis in children the infection is of bovine origin. Reference to the findings of the Royal Commission on Tuberculosis, with which he suggests we are not familiar, would reveal the fact that no detailed investigation into the etiological factors in the causation of tuberculosis of bronchial glands in children was made, and that in 50 per cent. of such cases as were investigated the type of the bacillus was doubtful.

Your reviewer appears to have overlooked the fact that since the publication of the report of the Royal Commission on Tuberculosis a considerable amount of investigation has been conducted as to the cause of root tuberculosis in children, and our inference that this type of tuberculosis is probably of bovine origin is supported by recent investigation. In the eighth annual report on the work of the Glenlomond Sanatorium, Scotland, Dr. W. T. Munro states: "In an investigation into the type of tubercle bacilli found in the tracheo-bronchial glands in children who have died from any cause, in over 50 per cent. of the cases the bacilli have so far been found to be bovine."—We are, etc.,

Hertford, May 23th.

THE EPIGLOTTIS IN RESPIRATORY OBSTRUCTION UNDER ANAESTHESIA.

SIR,—Mr. H. Mortimer Wharry in his account of respiratory obstruction caused by the epiglottis raises many interesting points, as also do Dr. Magill and Mr. E. D. D. Davis in their letters on this subject.

In my opinion the normal epiglottis never causes respiratory obstruction, but I have from time to time observed the epiglottis to be so soft that it can fall into the position described by Mr. Wharry. Such softening occurs only in cases of chronic inflammation where perichondritis of the epiglottis has been a feature.

The remedy for such a difficulty in respiration would appear, however, to be much simpler than that described by Mr. Wharry, for if the epiglottis does fall down it is only necessary to introduce a large-sized tongue depressor such as Lack's and, passing it well behind the tongue, pull strongly forwards and with the other hand do artificial respiration. In cases of real difficulty, of which I have met one, the introduction of the tongue depressor in this way and of a Hewitt's airway tube passed down behind it, and kept in its position by packing gauze deeply along each side of it, will not only keep the epiglottis in position, but will control any bleeding that is going on.

It must be emphasized that such cases are of exceeding rarity, and that generally it is the tongue which causes the obstruction. Tracheotomy or laryngotomy should, in my opinion, never be necessary for such obstruction. It would, however, not be possible, I think, to pass a catheter into the trachea in such a case, for obstruction such as this does not occur during the quiet breathing of deep anaesthesia. If it occurs at all, obstruction by the epiglottis must take place either during the later stages of induction, or, as in my cases, at a time when the patient is beginning to pass out of surgical anaesthesia. It is necessary for the patient to be deeply anaesthetized if we are to pass a tube into the trachea without undue delay.

That the epiglottis has a protective function of guarding the larynx against infected saliva dribbling on to its most anterior part as Mr. Wharry suggests can, I think, be proved to be true, for if we let a patient swallow a mouthful of any harmless dye such as 0.4 per cent. indigo carmine solution, we observe the dye to be retained in the pouch between the tongue and epiglottis, from which it passes slowly to the oesophagus by way of the sinus pyriformis. It is, moreover, on the posterior portion of the larynx that infection mainly falls when this is due to swallowing the infective products of septic teeth. A secondary mechanism of course exists, which, when the epiglottis is removed, prevents saliva dribbling on the vocal cords.—I am, etc.,

Wolverhampton, May 23th. A. LOWNDES YATES.

EARLY RECORDS OF THE ASSOCIATION OF APHASIA WITH RIGHT-SIDED HEMIPLEGIA.

SIR,—It has seemed to me remarkable that any special association of aphasia with right-sided hemiplegia was not recognized till modern times. In ancient and mediaeval times the death of princes and distinguished persons was often described, and a considerable number of these must have died from cerebral haemorrhage or thrombosis; not only was any connexion between the two above-mentioned symptoms not recognized, but even their association seems hardly to have been noted.

Richard Plantagenet, Earl of Cornwall and "King of the Romans," died at Berkhamstead Castle in 1272, not very long after hearing that his eldest son, Henry, had been murdered (1271) in the Cathedral of Viterbo by Guy de Montfort. Judging from the account of Thomas Wikes, Richard's cerebral attack commenced with right-sided hemiplegia and aphasia (see Thomas Gale, *Historiae Anglicanae Scriptores Quinque*, 1687, vol. ii. p. 96). I should like to hear of other early records of the association of aphasia with right-sided hemiplegia.—I am, etc.,

London, W.1, May 28th. F. PARKES WEBER.

Obituary.

BRYDEN GLENDINING, F.R.C.S.,

Late Research Scholar, Cancer Laboratories, Middlesex Hospita

We regret to record the death of Bryden Glendining, whi occurred at Aspley Guise, Bedfordshire, on May 18th.

He was born at Dunedin, New Zealand, in 1880. came to England in 1898, and entered Guy's Hospital; took the degrees of M.B., B.S.Durham in 1903. He h house appointments at Guy's Hospital during 1903 and 19 under Sir (then Mr.) Arbuthnot Lane, and later w resident surgeon at the Hertford British Hospital in Par He accompanied the present Queen of Spain to Madrid the occasion of her marriage, and he stayed in Spain about two years as the personal medical attendant of H Majesty.

After his return to England he became associated wi Mr. Comyns Berkeley and Mr. Victor Bonney, and w made pathologist to the Chelsea Hospital for Women; wh continuing to hold this post, he was elected in 1911 an Emden Research Scholarship in the Cancer Resear Laboratories of the Middlesex Hospital. During his th years' tenure of this scholarship he wrote nine pape nearly all of which were on the subject of malignant disea in its relation to gynaecology; perhaps the most importa was that on the spread of carcinoma by the Fallopian tu in which he put forward an entirely new view as to t invasion of the Fallopian tube by carcinoma from t uterus and ovary. He adduced evidence that it may brought about "by cancer cells which, coming in cont with the fimbriae or being swept into the lumen, engr themselves upon the columnar cells and thence travel deeper parts." This conclusion is of special interest view of the opinion now held by most pathologists th pelvic endometriomatosis is in many cases due to shifti of the epithelium lining the tubes or uterus. With t caution which characterized him, he saw that the possibil of lymphatic permeation from the ovarian growths co not be entirely excluded.

By this time he was definitely committed to gynae logical work, for he had become assistant surgeon to t Chelsea Hospital for Women as well as obstetric tutor a registrar to the Middlesex Hospital; in 1912 he beca gynaecological surgeon to the Hampstead General and Nor West London Hospital, but continued, among all these duti to carry out research work. He was already a m marked down among his fellows as destined to make a na for himself in the specialty at which he had worked persistently. Late in 1913 his friends learned with disn of a breakdown in his health. However, he resumed act work in 1914 at the Chelsea Hospital for Women and at t Hampstead Hospital, and became surgeon to the Duch of Bedford's War Hospital, which contained 102 beds Woburn Abbey and Woburn Cottage Hospital. He w now confronted with work of a general surgical charact and he had the fullest scope for the display of the pa cular genius he had for combining diagnostic acumen w operative skill. He was a bold operator, not hesitating undertake what his pathological knowledge told him w necessary; yet in actual manipulations a lightness a sureness of touch was shown in everything he did.

A second breakdown in health at the end of 1916 entai a rest of some months, but he returned to active work n year, and remained surgeon to the Woburn War Hospi until it was closed in 1920; he continued to act as surg to the Woburn Cottage Hospital until the early part 1925, when failing health compelled him to retire from a active work. The last years were borne with a patie and courage that nothing could dim.

The blow of 1913 was one from which he never rea recovered physically, but it brought into high relief fine qualities of the man. The splendid work he did in face of such a handicap will always be remembered by th who were in any way associated with him in it. married the daughter of Captain G. E. Hodgson, late 4 Regiment, who survives him with an only son.

A VETERAN.—The number of officers of the Indian Medical Service who joined it under the old East India Company is rapidly diminishing. The number surviving, so far as is known, was until the other day five. It is now reduced to four by the death on March 16th of Surgeon Major JOHN THOMAS DENISON MACKENZIE, M.D., Bombay Medical Service (ret.), aged 91. He took the M.R.C.S. in 1857 and the F.R.C.S. in 1870. He entered the I.M.S. as assistant surgeon on July 23rd, 1858, passing in second, became surgeon major on July 1st, 1873, and retired on May 8th, 1878, nearly half a century ago.

Medico-Legal.

HARNETT *v.* FISHER.

JUDGEMENT OF THE HOUSE OF LORDS.

THE House of Lords, consisting of Lords Sumner, Atkinson, Wrenbury, Carson, and Blanesburgh, on May 27th, 1927, dismissed the appeal of Mr. William Smart Harnett, farmer and fruit grower of Newington, near Sittingbourne, Kent, against the verdict and judgement entered for the defendant, Dr. *Holdrich Fisher, a medical practitioner of Sittingbourne*, at the trial of the action brought by Mr. Harnett before Mr. Justice Horridge and a special jury in the King's Bench Division, for damages for alleged negligence in certifying Mr. Harnett as a proper person to be detained under care and treatment under the Lunacy Act, 1890.

The certificate was signed on November 10th, 1912, and the writ in the action was issued on May 31st, 1922.

The defendant pleaded, first, that he acted in good faith and, with reasonable care in signing the certificate, claiming the protection of Section 330 of the Lunacy Act, 1890; and, secondly, that as the plaintiff had not issued his writ until May 31st, 1922—more than six years after the date of certification—he had allowed his right of action to be barred by the Statute of Limitations.

At the trial of the action the questions of the judge and the answers of the jury were as follows:

1. Was Mr. Harnett of unsound mind on November 10th, 1912, when he was certified by Dr. Fisher?—No.
2. Did Dr. Fisher act with reasonable care in certifying him?—No.
3. Damages?—£500.

Legal argument ensued as to whether the plaintiff's right of action was barred because he did not issue his writ within six years of the date of certification. The defence urged that, as the jury had found the plaintiff sane on November 10th, 1912, the Statute commenced to run against him on November 10th, 1918, but the plaintiff replied that although the jury had found him to be sane on November 10th, 1912, he was, in fact, detained as a lunatic, and it was this disability—specially excepted by the Statute—which prevented him from bringing his action, and he must be deemed to have been insane for the purposes of the exception.

Mr. Justice Horridge, however, entered judgement for Dr. Fisher, accepting the argument of the defence that the jury, having found that on November 10th, 1912, the plaintiff was a sane man, his right of action was barred by the Statute of Limitations, and this judgement was affirmed by the Court of Appeal, consisting of the Master of the Rolls, Warrington, and Scrutton, L.JJ., subject to a variation as to costs.

The facts of the case are fully stated in the case Harnett *v.* Bond and Adam, reported in the BRITISH MEDICAL JOURNAL of March 8th and April 12th, 1924. March 14th and May 23rd, 1925, whilst the arguments on the appeal in the present case in the House of Lords are reported in the issue of March 12th, 1927, at page 496.

The appellant appeared in person; Mr. Neilson, K.C., and Mr. Carthew (instructed by Messrs. Le Brasseur and Oakley, for the London and Counties Medical Protection Society) appeared for the respondent doctor.

Appeal Dismissed.

Lord Sumner, in his judgement, said the ground of the decision of both courts below could be tersely put thus. The jury found conclusively that on the day of the examination the appellant was of sound mind, and he was not shown ever to have been otherwise. If, then, the appellant never had been *non compos mentis* he could not bring himself within the disability section (s. 7) of the Statute of James, and the period of six years ran from November 10th, 1912. The appellant could not be allowed to blow hot and cold, and to say for the purpose of getting the verdict and damages that he was sane all along, and yet for the purpose of meeting the plea of the statute that he must nevertheless be deemed to have been insane so as to prevent time from running. The appellant, who appeared at their lordships' bar in person, not only conducted himself with great propriety and moderation, but laid his legal argument before their lordships in a way which was equally of assistance to their lordships and to his own case. He said, briefly, that under the Lunacy Act and for its purposes he was made a lunatic and treated in person and property accordingly, and that for the purpose of bringing the present action he was, in fact, to all intents, as much disabled as if he had been *non compos mentis*; that, as a practical matter, it would have been impossible for him to have begun his action till after he had made his escape; and that, on a "liberal" construction, the statute should be read as bringing that state of things within the disability section. To this his lordship was afraid he must say, as was said by both courts below,, that the Act did not say so, and could not be made to say so, without wresting it from its language in a way that was not permitted to them. The object of the Act was to protect defendants against belated claims, and not merely to protect those defendants who had a good defence, and to that extent needed no protection, but to protect those also who had not, or who owing to lapse of time could no longer count on making out a sufficient answer. The present action was an action on the case, and being within the Act was prima facie barred unless the appellant could bring himself within the only words in the disability section which touched him—namely, *non compos mentis*. What those plain words meant was further shown, if that were necessary, by the words used to express the opposite state—namely, "of sound memory." They described an actual mental condition, which the jury's word "sane" negatived, and not a treatment imposed, or a disability suffered because the plaintiff had been wrongly supposed to be in that mental state, by whosesoever fault—even that of the defendant himself—it might have been brought about. On one occasion, about a month after the reception order was made, the appellant was allowed to leave the asylum provisionally, and was actually at large for some two days. After his return he was in frequent communication with his solicitor, and occasionally saw him personally. His lordship thought, however, that one might accept the statement that even the issue of a writ against the respondent was beyond his power, much as it would have been if, though sane, he had been bedridden and in poverty. But, in the latter case, no one could doubt that his disability was not one of those named in the section. Neither would it do, if he were called insane, when he was really sane. The question was not, as the appellant put it, of the status of a lunatic imposed on him after the making of the reception order, but of his mental condition of sanity or insanity, and that had been finally disposed of in his favour by the verdict. His lordship was not concerned to justify what the Legislature had enacted, or to regret that it had gone no further to assist persons in the appellant's position. He, therefore, agreed entirely with the conclusion of the Court of Appeal.

A question was raised by one of their lordships whether the right statutory limitation had been relied on, and whether Section 331 of the Lunacy Act, 1890, or the Public Authorities Protection Act, 1893, by which that section had been repealed, did not apply. All their lordships were of opinion that leave to amend ought to be granted to the respondent in the circumstances to enable him to plead the Act of 1893, but it appeared to him (Lord Sumner) that no amendment was needed, because it really was the Statute of James that applied to this case. What was the action to which the Act of 1893 applied? It was one brought for doing, or neglecting to do, an act under any statute of the kind described, in this case the Lunacy Act. So far as the present action was concerned, the only such act was signing the certificate in the prescribed form. When, however, one looked at the statement of claim, and still more at the substance of the case as proved at the trial and since alleged on two appeals, the gist of the action was not the signing of the prescribed form of certificate but the lack of care in examining into the appellant's mental state and in forming an adverse opinion about it. The negligence for which the action was brought could only arise in that connexion. The claim was not for breach of a statutory but of a common-law duty. Negligence as a medical practitioner acting in the course of his private practice was what was charged against the respondent. Any principle on which that cause of action could be sustained would be equally applicable if the defendant had signed nothing, but had given his opinion to the magistrate orally. The rest was either a separate cause of action under the Lunacy Act, for which no damage could be recovered, since the detention order was the order of the justice and not of the doctor, or was a mere item in the damages claimed for the negligence. It might be that in view of Section 317 (2) of the Lunacy Act, 1890, the proceedings to be taken in case of misstatements made in medical certificates under the Act were criminal proceedings only. In his opinion the present cause of action being on the case for an alleged common-law breach of duty, the Statute of James was the statute applicable. He thought that, whether the pleadings were amended or not, the appeal ought to be dismissed with costs.

Judgement of Lord Atkinson.

Lord Atkinson, in his judgement, said their lordships concurred with the Court of Appeal. They thought the decision of the Court of Appeal was perfectly sound and right on the question raised before them. During the progress of the hearing in that House, however, attention was called by one noble lord to the question of the possible application of the provisions of the Public Authorities Protection Act, 1893, to certain provisions of the Lunacy Act of 1890. This was a matter of such importance that it should be dealt with. The Act of 1893 repealed Section 331 of the Lunacy Act, 1890, which provided that any action brought by any person who had been detained as a lunatic against any person for anything done should be commenced within twelve months next after the release of the party bringing the action. This section would not apply to the appellant, even if not repealed, as he was not

detained,

mental state of health, was bound to do the work he had undertaken to do with reasonable care and skill. In this case it was found by the jury that the respondent was guilty of negligence in giving a certificate pursuant to the provisions of Section 4 of the Lunacy Act, 1890. Well, negligence was a breach of duty, but the question was to whom was this duty to use reasonable skill and care owed. This action was founded on the assumption that it was owed to the appellant. The additional question whether it was owed to any other person or body, and if so, to whom or what authority was the alleged act of the defendant in exercising due and reasonable skill and care in granting his certificate, an act done in pursuance or execution or intended execution of an Act of Parliament, or of any public duty, or authority, or in respect of any alleged neglect or default in the discharge of a public duty or in the direct execution of a statute or language of the Act did not cover all the acts which a local authority had power to perform. It was because the act was one which was either an act in the direct execution of a statute or in the discharge of a public duty or in the exercise of a public duty that it was covered. It was difficult to see on what principle a petitioner who was guilty of negligence in framing his statement of particulars, but not guilty of misstatements of any material fact, should not be liable to be sued for that negligence, or a doctor might be who negligently framed his certificate on which the alleged lunatic. If the latter came within the Act of 1893, the former would seem necessarily to be within it, as he was within the 317th section of the Act of 1890, and also to be referred to Section 28 of the Act of 1890, and also to sections 29, 31, 32, and 33, and proceeded to say that thus a practitioner who signed one of these certificates from the institution in which the lunatic was to be confined. not have any interest in the payments made on account patient confined. In one sense, the general public in a had an interest in the ability, skill, qualification, and ss of the medical men residing and practising in that . The aid of one or more of these could, in any case, be obtained by private contract, but in the matter of on of an alleged lunatic to an asylum or house licensed, of a certificate owed no duty to the general public or to institution or authority *whatever*. He was not a employee of the State or of any municipal body certain services for such bodies. He was simply a medical man by a patient to give an opinion as to 's state of health, as he would be to diagnose the lth of any patient who, in his daily practice, called prescribe for him. Lord Atkinson, therefore, was nion that the Public Authorities Protection Act, 1893, to the appellant's action, and that his remedy was Act of James.

Judgement of Lord Blanesburgh.

burgh, in his judgement, said by the verdicts now the plaintiff, in Lord Buckmaster's words in nd: "while a sane man has been imprisoned in ic asylum and it follows that he has suffered a for which no money payment can provide an nsation." The plaintiff's moderation and ability s case only served to disclose as in a flash the rong. But great as it had been it could furnish for an order upon the respondent to make the which the jury here had awarded against him, appellant's claim against the respondent was he objection that it was had been properly taken. te of James applied to this case at all, it must action was out of time. The argument of the e construction of that Act, sensible and forcible ft almost untouched the reasoning and con- orridge J. and the Court of Appeal, but that his (Lord Blanesburgh's) mind, at all events, whether the limitation statute to which such applicable could really have been left by govern this particular claim. If it were appropriate limitation period to hold the n the plaintiff and defendant, the Statute of e singularly unsuited to a claim like the indeed, whether its true construction was ppellant contended, or that put forward by either view, the statute must, if applicable, similar cases, dire results in its train. If, llant's contention were to be upheld that in e duration of a plaintiff's *de facto* insanity esult of the defendant's certificate was, like sanity, to be excised from the limitation d be oppressive on a medical defendant t here acted, in perfect good faith, that, iod after the disability ceased, but in a s later, he might be called upon to justify ost, if not entirely, forgotten. If, on the ame *de facto* disability, with consequences ing and paralysing in their incidents and in fact insane, time, as the respondent sly running in favour of the defendant, y that the period of restraint should be the wrong done to the plaintiff in that s, for him to be deprived by the statute unjustifiable, or even malicious, the ve been. But the improbability that

the Legislature had left a claim of this kind to be governed in the matter of limitation by a statute so clumsily inappropriate was shown also by considerations still more pertinent. The provisions of Section 82 of the Lunacy Act itself were even more significant in that direction. By that section it was provided that the Secretary to the Commissioners should, *upon the discharge* of a lunatic, furnish to him upon his request, free of expense, a copy of the reception order and certificate or certificates upon which he was confined, and, if the order was made upon petition, also of the petition and statement of particulars upon which the reception order was made. That was to say, it was only upon his discharge that the person considering himself to have been unjustly confined was to be supplied with a copy of the certificate upon which his claim to redress in such an action as this depended. Could it have been supposed by the Legislature when enacting that section that the claim of the person so unjustly confined might by that time have become statute-barred? He (Lord Blanesburgh) did not think so, and thus was he led to inquire for himself whether some other period of limitation than that devised by the Legislature for a claim like this, a limitation period which would be consistent with the injustice to those in the appellant's position which the Statute of James, had it been left applicable, might bring in its train. And, on examination, he had reached the conclusion that there was such a limitation period in fact specially prescribed by statute; and, relatively unimportant as in the present instance the result might be to the appellant, the principle involved might be of such wide-reaching consequences in other cases that he made no apology for directing their lordships' attention to the matter with some particularity. In his original defence the respondent had pleaded only one limitation, Section 331 of the Lunacy Act, 1890, which provided that "any action brought by any person who has been detained as a lunatic against any person for anything done under this Act shall be commenced within twelve months next after the release of the party bringing the action," a provision which, it would be noted, was in entire consonance with Section 82, to which reference had already been made. The corresponding Section 105 of the Lunacy Act, 1845, then in force, was treated by Crompton J. in *Hall v. Simple* as the appropriate limitation statute in a case like this. Section 331 of the Lunacy Act was accordingly well pleaded, but that section was repealed in 1893, a fact which apparently was overlooked when the defence was delivered. Presumably, the repeal was subsequently discovered by the defendant's advisers, and, under an order dated December 16th, 1925, the defence was amended by adding a paragraph to the effect that the plaintiff's alleged rights of action were barred by the Statute of James, the Limitation Act, 1623. In other respects, however, the defence remained unamended; Section 331 of the Lunacy Act, 1890, was still pleaded in paragraph 4. If he (Lord Blanesburgh) had correctly appreciated and faithfully recorded the true limits and scope of this suit as fought and decided, he could not himself doubt that if Section 331 of the Lunacy Act had remained unrepealed, that section, and it alone, prescribed the only period of limitation to which this action was subjected. Was, then, that position, which went back at all events to 1845, entirely lost now, although Section 82 of the Act still remained in force? In his (Lord Blanesburgh's) judgement, no. The section, although repealed, still spoke, albeit in modified terms. The repeal was effected by the Public Authorities Protection Act, 1893, an enactment whose purpose was to generalize and amend certain statutory provisions for the protection of persons acting in the execution of statutory or other public duties, and difficult as it had been in many cases to ascertain the true effect of that enactment, no difficulty arose in that instance. Lord Blanesburgh read the provision in the Act of 1893, prescribing a limitation of six months, and said he had no doubt that in that amended form Section 331 of the Act of 1890 still operated, applicable as before to the respondent's certificate but shortening the period after what in the Act of 1890, in the case of a plaintiff who had been detained as a lunatic, was termed his "release," to a term which without doubt or possible question made it a complete bar to the present suit. For while, if Section 331 had been the section applicable, there might have been some question whether the detention for which the respondent was responsible came to an end within twelve months before the institution of the action, he (Lord Blanesburgh) —in agreement with Lord Atkinson—thought it had come to an end more than six months before its institution. The appellant escaped finally from confinement on October 15th, 1921, and this action was not commenced until May 31st, 1922. In his (Lord Blanesburgh's) judgement, therefore, the Act of 1893 was the Statute of Limitations, and the only Statute of Limitations, which applied to that action. If pleaded, it would have been a complete answer. But it was not pleaded. Accordingly, unless leave was now given to the respondent to amend his defence by rectifying that omission, he had no answer to this appeal.

Lord Blanesburgh proceeded to say that the terms on which leave should be given to amend, if they rested with him, would be that as the price of the amendment the respondent should lose the costs of the appeal. As would be seen, however, the appellant gained little by this finding in his favour, but other plaintiffs in his position might gain much. The view he (Lord Blanesburgh) had presented might be wrong. But, if it was, a very serious state of things was thereby disclosed. For it resulted that Section 331, prescribing a period of limitation at least as old as the Act of 1845, and sensible and fair in its operation, had been repealed by a general Act with no corresponding provision substituted, and with the result that plaintiffs in the position of the appellant were now, for the first time, he (Lord Blanesburgh) thought, relegated to the Statute of James, which was entirely inappropriate to their case. If this appeal fulfilled no other

useful purpose it would at least have served to draw the attention of those engaged in the amendment of the Lunacy Laws to a matter which was not unworthy of their consideration.

Lord Wrenbury and Lord Carson concurred.

DE FREVILLE *v.* DILL: RE-HEARING.

AFTER a hearing, which lasted eight days, of the action in the King's Bench Division, before Mr. Justice McCardie and a special jury, brought by Mrs. May de Freville against Dr. A. V. Dill, a medical practitioner of Brimscombe, Stroud, for damages for alleged lack of reasonable care in certifying her to be a lunatic on June 9th, 1926, and for alleged assault and false imprisonment, the jury, on May 28th, returned a verdict for the plaintiff and assessed the damages at £50. Judgement was deferred until next term.

Dr. Dill pleaded that he signed the certificate in good faith and that he acted with reasonable care, claiming the protection of Section 330 of the Lunacy Act, 1890; he further said that his conclusions regarding the plaintiff's condition at the time of her certification were correct.

It will be remembered that when this case was first heard before Mr. Justice Avory the special jury came to a premature decision adverse to the defendant before the evidence for the defence was concluded, and that, in those circumstances, Mr. Justice Avory discharged the jury without recording their verdict. The facts of the case are fully set out in the report of the previous hearing, which is contained in the issue of the BRITISH MEDICAL JOURNAL of April 9th, at page 705.

Briefly, the plaintiff's case was, that on June 9th, 1926, when she returned to Oakridge Vicarage after visiting her father, her husband put her out of the vicarage. She was very angry, and, as she desired to see her little son, she entered the vicarage by the servants' entrance. Her father-in-law, the vicar, however, kept her in the servants' hall while he telephoned to the defendant, who came and certified her as suffering from acute mania, ordering her removal to Gloucester County Asylum. The following day the plaintiff was duly examined, pronounced sane, and discharged.

Mr. J. W. J. Cremlyn and Mr. Comyn Maitland (instructed by Mr. H. Coulson) appeared for the plaintiff; Mr. Singleton, K.C., and Mr. W. H. Gattie (instructed by Messrs. Le Brasseur and Oakley, for the London and Counties Medical Protection Society) appeared for the defendant.

The Summing-up of Mr. Justice McCardie.

On the eighth day of the hearing Mr. Justice McCardie summed up, and said that, as any suggestion of bad faith had been wholly withdrawn, the only issue for the jury to consider was whether Dr. Dill had exercised reasonable care in certifying the plaintiff. The action was important, first, from the point of view of Mrs. de Freville, because it involved the liberty of the subject; secondly, from the point of view of Dr. Dill, because it affected his character and reputation as a medical man; and thirdly, from the point of view of the general public, to whom the administration of the lunacy law was of vital concern. Litigation of the character of the present case had not been infrequent in recent years, and it might be that, as a result of it, many medical men had refused to take any part in certifying patients under the Lunacy Acts. It might be that, whatever was the verdict of the jury in the present case, many more medical men would decline to give certificates if they might be made subject to litigation because they had become embroiled in embittered family strife with which they had nothing to do. It was a serious matter that the Lunacy Acts contained no definition whatever of insanity, of unsoundness of mind, or of lunacy; that they provided no test, set no standard, and gave no guidance with regard to those matters. The keynote throughout the Acts was, first, the welfare of the patient, and secondly, the public safety, which might require that the patient be put under care and treatment. From the medical point of view no textbook gave any definition of insanity, unsoundness of mind, or lunacy, and he had never in the course of his experience at the Bar and on the Bench known a doctor who was able to give a definition of those things. That illustrated the grave considerations which should be present to the mind of a jury who had to decide whether or not a doctor had acted with reasonable care. A doctor who was called in to deal with an alleged lunatic was dealing with the most difficult subject known to the medical profession. The forms taken by unsoundness of mind were many, while diagnosis and classification were difficult. Not only did the forms and symptoms vary, but each varied in degree, in gravity, and in intensity. Symptoms and outbreaks might be intermittent, and might vary year by year, month by month, and day by day. What, then, was the position of a doctor who was dealing with a question such as that? The matter had been put in the best and most practical working form for the consideration of a jury by Lord Haldane, in the course of the judgement he delivered in the House of Lords in Everett *v.* Griffiths, reported in the Law Reports, 1921, 1. A.C., 631, at page 654, when he said of the plaintiff in that case: "To-day he is sane in his conduct, and probably was so very soon after the occurrences in question. But the point is, whether at the time of these occurrences he had so lost his capacity for self-control as to be, temporarily at least, to all appearances of unsound mind within the meaning of the statute which takes account of his relations to others as well as to himself." The jury must remember that the Lunacy Acts had to be administered and certificates had to be given not only by London specialists and other experienced practitioners in great cities, but also often by ordinary country doctors. It was one thing to come to a decision whether or not a certificate should have been given in the present case after several days' hearing of the evidence on both sides and the addresses of counsel; it was another thing to come to a decision in a room in a country parsonage. A general medical practitioner gave no warranty of special skill or knowledge. He was bound to exercise due care having regard to the skill and knowledge which he actually possessed.

Universities and Colleges.

VICTORIA UNIVERSITY OF MANCHESTER.

THE county borough of Stockport has increased its annual grant to the University from £250 to £400.

The Council has accepted the resignation of Dr. G. S. Wilson, Lecturer in Bacteriology and Assistant Director of the Public Health Laboratory, on his appointment as Reader in Bacteriology and Immunology in the University of London.

NATIONAL UNIVERSITY OF IRELAND.

THE following appointments have been made:

University College, Dublin.—Professorship of Medicine, Henry F. Moore, M.D., D.Sc.; Professorship of Syste[illegible]nan, M.B., B.Ch.; Professorship of Pathology, O'Farrell, F.R.C.S.I.; Professorship of Publi[illegible] William D. O'Kelly, M.D., D.Sc.

The following degrees and diplomas were conferred on May 14th

M.B., B.Ch., B.A.O.—T. F. J. Ryan, J. A. Browne, M. Coghlan, C. J. McCarthy, J. V. McLoughlin, J. E. MacMahon, J. P. Marren, A. V. O'Brien, Catherine Purcell, J. G. Ryan, E. P. Walsh.

M.D.—J. M. Hayden, H. J. Phillips, J. C. Troy.

D.P.H.—Margaret Bergin, M. Downey, Hilda M. Doyle, Mary P. Power.

The Services.

INDIAN MEDICAL SERVICE DINNER.

THE annual dinner of the Indian Medical Service will be held at the Trocadero Restaurant on Wednesday, June 15th, at 7.15 for 7.30 p.m. Major-General R. W. S. Lyons has been invited to take the chair. Tickets and all particulars may be obtained from the joint honorary secretary, Colonel J. J. Pratt, I.M.S. (ret.), 18, Nevern Mansions, Warwick Road, London, S.W.5.

DEATHS IN THE SERVICES.

LIEUT.-COLONEL JOSEPH WILLIAM TOWNSEND ANDERSON, Bombay Medical Service (ret.), died at West Kensington on May 12th. He was born at Karachi on November 5th, 1852, the son of Joseph Anderson of the I.M.D., and studied at the medical schools of St. [illegible] Charing Cross, and at Edinburgh and St. [illegible] he took the L.S.A. in 1878, and the L.R. [illegible] he became F.R.C.S.Ed. in 1891. Entering the I.M.S. as surgeon on October 2nd, 1880, he became lieutenant-colonel after twenty years' service, and retired, with an extra pension, on April 15th, 1906. For some years before his retirement he had been civil surgeon of Ahmedabad, and superintendent of the Byramji Jijibhai medical school, and of the lunatic asylum at that station. He served in the Burma war in 1886-87.

Lieut.-Colonel William Hamilton Kenrick, Indian Medical Service (ret.), died at Virginia Water on May 7th, aged 58. He was the son of William Wynn Kenrick, colliery proprietor and mining engineer, of Ruabon, and, after taking the M.R.C.S. and L.R.C.P. in London in 1895, entered the I.M.S. on January 28th, 1897, being one of the first batch gazetted to the General List of the I.M.S., which started in that year. He became lieutenant-colonel on July 29th, 1916, and retired on July 28th, 1924. He served on the North-West Frontier in the campaigns of 1897-98, including the Tochi Valley campaign (medal with clasp); the operations on Samana and in the Kurram Valley (clasp); and Tirah, in the actions at Dargai and on the Sampagha and Arhanga Passes (clasp); also in the China war of 1900, when he took part in the relief of Pekin, and in the actions at Pientsan and Yangtsen he was mentioned in dispatches and received the medal with a clasp. In May, 1905, he took civil employment in the Central Provinces, and remained there for the rest of his service, except that he was recalled to military duty from October, 1918, to May, 1921. He was the author of a work on *Malaria in the Central Provinces*, 1916.

Medical Notes in Parliament.

[FROM OUR PARLIAMENTARY CORRESPONDENT.]

House of Commons, after spending another three days ommittee on the Trade Disputes and Trade Unions Bill, urned over Whitsuntide on June 2nd. On May 31st Mr. on introduced a bill to provide for the humane slaughtering nimals. The backers of this bill included Dr. Drummond ls.

"Trade Unionism" and Medicine.

May 27th, when the House of Commons was in Committee Clause 4 of the Trade Disputes and Trade Unions Bill, Vernon Davies made a personal statement. He had found some of the statements which he had made on May 23rd. answering allegations by Mr. J. J. Lawson concerning the ish Medical Association, were inaccurate. Dr. Davies asked per- ion to read a letter from the Medical Secretary of the British ical Association, saying this fully explained the matter. He d that he was not reflecting in any way on Mr. Lawson, merely wished to put himself right at the first opportunity. Chairman (Mr. J. F. Hope) said there could be no objection hat. Dr. Davies then read the letter he had received from Medical Secretary of the Association. This ran:

"In your references to the British Medical Association you made certain statements which are not borne out by the facts, and I feel sure you would like to be put right in case the question should arise on a future occasion. The form of application for membership of the British Medical Association which a man who wishes to join signs, says: 'I agree if elected to pay the subscription and to abide by the articles and by-laws of the Association for the time being in force, and the rules of the Division or Branch to which I may at any time belong.'

"In twenty-five years only 35 members have been expelled, and these have all been for conduct which has been declared after a careful inquiry to be 'detrimental to the honour and interests of the medical profession.' Then, you go on to describe what happens if a man takes an appointment to which the Association objects. You say the Association says, 'We cannot penalize you. We cannot turn you out of the Association, and we cannot advise anybody to have nothing to do with you.' We can, as a matter of fact, turn such a man out of the Association, and very occasionally we have done so. As regards advising people to have nothing to do with him, there is the power, after a careful inquiry surrounded by all sorts of safeguards, and after declaring that the conduct of the practitioner has been 'detrimental to the honour and interests of the medical profession,' for a Division to issue a notice to its members stating that 'It is undesirable that a member of the Division should meet in consultation or accord any professional recognition (other than such as may be necessary in the discharge of an official duty by a public medical officer or in circumstances of great urgency affecting the life of a patient) to a medical practitioner who shall have been declared by resolution of the Division to have acted in contravention of any rule or resolution of the Division as to professional conduct, of which such practitioner shall be proved to have had notice in accordance with these rules, or who shall have been declared by resolution of the Division to be deemed guilty of conduct detrimental to the honour and interests of the medical profession.' This action has only been taken with regard to seven practitioners since 1962. I think it only right that I should make clear to you that, like all other associations, we have certain legal powers of dealing with members whose conduct is considered to be against the interests of the Association, and we also have the right, as has been proved by legal decisions, both general and in our own case specifically, to decline to meet persons professionally after an inquiry made in a judicial manner and in accordance with rules which are carefully laid down."

The Chairman remarked that this appeared to be a statement ling with the disciplinary regulations of the British Medical ociation. It could not be discussed and was not relevant to a ussion on the political funds of trade unions. Dr. Davies arked that on May 23rd he had stated specifically that members the British Medical Association were not expelled and that they re compelled to meet in consultation, when a life was at stake, ofessional men of whose conduct they disapproved. The letter had read, an official letter from the British Medical Association, wed that members had been expelled from the Association and at they could withdraw. He thanked the House for allowing n to make the explanation. Mr. A. V. Alexander asked Dr. avies to tell the Committee whether the British Medical Associa- n paid any of the election expenses of doctors who sat in the use; whether they kept their funds separate, and whether any mber could reclaim. The Chairman intervened, and Dr. Davies marked that Mr. Alexander's question was irrelevant, but that would afterwards give the information asked, so that it could passed on to Labour members. Speaking on the amendment fore the House, Dr. Davies said that in Lancashire trade union ficials and those of other bodies had a method of canvassing d collecting subscriptions at the workers' houses, usually from e wives. He argued that the collection of the political levy such means should be prohibited. Mr. Lee asked if Dr. Davies w that medical men's salaries were paid in Lancashire by this ribed. Dr. Davies said he wished that members would forget r the moment that he was a medical man. He was speaking as the representative of an industrial constituency, with a knowledge of the industrial and social life of the workers, acquired as a factory surgeon. Mr. Tinker congratulated Dr. Davies on having the courage to rectify the mistake he had made.

Mr. Cape said that certain medical men had resorted to the canvassing methods against which Dr. Davies had spoken. They had done so not for political but for financial purposes. When health insurance became compulsory, doctors who had been the medical advisers of men, asked those men to sign forms so that those practitioners might become their panel doctors. Mr. Mackinder also referred to Dr. Davies's statement about the collection of trade union subscriptions from door to door and declared that hon. member did not understand the trade union movement.

Small-pox.

Answering Mr. West Russell, on May 26th, Sir Kingsley Wood said small-pox had been prevalent in Northumberland since 1924. Up to May 21st, 1927, approximately 2,300 cases had been notified. The areas chiefly affected were Ashington, Bedlington, Newcastle, Morpeth, Prudhoe, and Tynemouth. The Minister of Health thought the local authorities had adequate powers and that these powers were being exercised. The original source of the infection was unknown. In a number of cases where vaccination failed to protect it had been done many years ago. The Minister desired the public to know that the most effective measure against small-pox was to make free use of public vaccination. Dr. Salter asked whether the Ministry was satisfied that the mild disease in Northumberland and Durham was the same as the disease recently so fatal at Hendon. Sir Kingsley Wood said the Ministry was satisfied that the disease was small-pox and that vaccination was the best preventive.

On May 30th Sir K. Wood told Sir N. Grattan Doyle that the Minister of Health had not yet obtained complete information as to the vaccinal condition of those cases of small-pox which had occurred in Northumberland and Durham during the past eight weeks. This information, which should cover all cases at present known to be infected, would shortly be available.

Asked whether he was prepared to take steps to ensure that statutory declarations of parents against vaccination should not be open to public inspection, Mr. Chamberlain said this course would not serve a useful purpose. The register under the Vaccination Act of 1867 would still be open to inspection.

Government Vaccine Lymph.

On May 30th Sir K. Wood, replying to Sir W. Davison and Dr. Vernon Davies, said that the reputation of Government lymph had been achieved, not only by its quality and consistency, but by the close attention given to its results by means of official inspection and records. If Government lymph were to be made available to private practitioners generally, it would appear very difficult, if not impossible, to ensure similar checks and controls. As from August next all vaccine lymph sold in this country would by virtue of the Therapeutic Substances Act, 1925, come under official control and would be required to conform to prescribed standards of potency and purity. The Minister of Health proposed to give some further consideration to the question, but it seemed doubtful, in view of the foregoing observations, whether any departure from present practice would be justified.

Dr. Davies asked if Sir Kingsley Wood had seen the letter on this subject from Dr. S. Monckton Copeman—who was one of those who originally used "glycerinated lymph"—which had appeared in the *Times*. Having in mind the prevalence of small-pox, would it not be possible to see that Government lymph was sold to practitioners? Sir K. Wood said that there was no mention in the letter of the very important effect the Therapeutic Substances Act would have. Sir W. Davison asked whether it would not be desirable to make some temporary arrangement until August to supply lymph to any practitioners who desired to have it. Sir K. Wood replied that in all cases where there was an epidemic arrangements were made with the medical practitioners for the supply of Government lymph. Under the new Act the natural desire, which everyone shared, that all lymph should be of the proper standard of efficiency would be achieved.

Shop Acts, 1920 and 1921.

On May 25th, at a sitting of the Committee which is inquiring into the working of the Early Closing Acts, evidence as to the nutritive value of ice-cream was given by Mr. A. Pompa, secretary of the Ice-cream and Temperance Traders' Federation of Great Britain. He said that ice-cream had three or four times the calorie content of fresh milk. When ice-cream was unsold at night it was not necessarily thrown away. More ice and salt were packed round the freezer in the tub so as to keep the ice-cream hard and prevent bacterial contamination, and the ice-cream was sold the next day. In the case of small shops, it could be taken for granted that extra supplies of ice and perhaps of freezing salt were not available until the next morning. In this case ice-cream melted during the night and bacteria bred. It probably also picked up metallic contamination from the metal freezer. The Committee adjourned till May 31st.

National Health Insurance.—Answering Mr. Cooper, Mr. Chamberlain said he had submitted the recommendations of the Royal Commission on National Health Insurance to the Consultative Council on Approved Societies' Work. Five meetings had been devoted to considering the recommendations, and the views of the Council thereon had been communicated to him.

A few recommendations remained to be considered and would come before the Council at an early date. An amending bill would then be prepared, but there was little likelihood of its introduction during the present session.

Foot-and-Mouth Disease in Switzerland.—On May 30th Major Ainsworth asked whether, in view of the existence of foot-and-mouth disease in Switzerland, the Minister of Agriculture was satisfied that the condensed milk imported into Great Britain from that county was free from contamination. Mr. Guinness said that he was informed that the process of condensing milk necessitated the maintenance for some time of temperatures sufficient to destroy the virus of foot-and-mouth disease.

Shanghai Defence Force.—On May 31st Sir L. Worthington-Evans said that he was unable to state the total number of admissions to hospital of troops of the Shanghai Defence Force. The average weekly number of officers and men of the force and the permanent garrison at Hong-Kong, including Indian troops, who were in hospital during the four weeks ending May 20th was 15 and 860 respectively.

Motor Horns.—Colonel Ashley, replying on May 31st to Mr. Pethick-Lawrence, who asked if he had received complaints as to cases of nervous shock caused by the unnecessary use of strident motor horns, said he was aware that unnecessary noise was sometimes made. The point had been under consideration in connexion with the Draft Road Traffic Bill, but it seemed to him more a question of education in the courtesies of the road than a matter for legislation, as it would be extremely difficult to lay down a definite and enforceable standard of noise.

Dirty Milk.—Sir K. Wood, replying to a question on May 31st, said that the Minister of Health had seen the report of the medical officer of health for Workington, in which it was stated that 79 per cent. of the milk for sale was found to contain cow-dung, hairs, and dirt. The samples mentioned in that report were classified as 31 per cent. clean, 31 per cent. fair, and 38 per cent. dirty. In a later report, which had been presented to the town council within the last few days, a marked improvement was indicated, the result of an examination of a further set of samples being given as 75 per cent. clean, 12.5 per cent. fair, and 12.5 per cent. dirty. In reply to another question it was stated that the Minister of Health had no reason to believe that the licence fees paid by producers of graded milk, which represented only a part of the cost of inspection and bacteriological examination, had had a deterrent effect on the production of clean milk. He did not at present propose to abolish the fees.

Ornamental Waters.—Captain Hacking, replying on May 30th to Sir W. Davison, who asked if his attention had been called to the odour arising from the ornamental water in St. James's Park, "which in some cases had caused sore throats to those sitting by the water," said that attention had been drawn to the matter. Measures were being taken which, it was hoped, would provide an effective remedy. Sir W. Davison asked if Captain Hacking was aware that the same thing occurred in 1910 and 1911, and that then it was successfully dealt with. Captain Hacking said that the Office of Works, in order to effect economy, had not run fresh water continuously into St. James's Park lake. The pumping of water from the Serpentine, however, was creating a current which would probably have the desired effect.

Pasteurized Milk.—The Ministry of Health provisionally estimates that between 5 and 10 per cent. of the liquid milk sold in England and Wales is pasteurized.

THE COLONIAL CONFERENCE.

NEED FOR RESEARCH, MEDICAL AND OTHER.

THE Colonial Office Conference, in which officials representing Crown Colonies and Protectorates have been meeting the Colonial Secretary, Mr. Amery, at Downing Street, ended on May 31st. In his closing statement, Mr. Amery remarked that the Conference had endorsed wholeheartedly the principle of an efficient central organization in the field of scientific research. The Conference had instructed the new joint Medical Research Council, of whose setting up it had approved, to work out proposals for a scheme of medical research which would be on no less broad a basis than the scheme of agricultural research which the Conference had considered and approved on May 27th. In the same report the Conference's Committee on Colonial Scientific and Research Services stated that the British Colonial administrations were responsible for the health and prosperity of a large number of human beings, though the number was small in proportion to the territory they inhabit. This comparative sparsity of population was most noticeable in tropical Africa. The area of the tropical African dependencies was greater than that of India and Burma, but their population was less than one-sixth of that of those countries. This sparsity of population was mainly due, on the one hand, to centuries of warfare and to the slave trade; on the other, to the ravages of disease—diseases of man and diseases of stock. The establishment of the Pax Britannica and the development of an efficient administration had done away with warfare and the slave trade, but the Committee remarked that medicine, in alliance with veterinary science, could alone combat disease. The population of the Colonies should increase rapidly as the result [illegible] the progress in tropical medicine of the necessity for shielding the [illegible] f disease the Committee recalled more than one-tenth of the native population of Uganda was wiped out by trypanosomiasis. There was no organization whatsoever in the Colonies which viewed the problems of science as a whole.

Reviewing the present position of medicine in the Colonies, the report remarked that the first great stimulus to research in any branch of science was given in the closing years of last century, though much work of great value had previously been done. While Mr. Joseph Chamberlain held the seals of the Colonial Department two great institutions were founded—the London and Liverpool Schools of Tropical Medicine. At the same period the Tropical Diseases Research Fund, with an advisory committee, was created to advise the Secretary of State on the administration of the Fund and on any matters connected with medical research that might be referred to it. Since that time the Bureau of Hygiene and Tropical Diseases had been instituted to deal with the collection and distribution of information with regard to hygiene and tropical diseases, including the diseases of animals.

The Advisory Committee of the Tropical Diseases Research Fund was now in progress of reconstitution. A new body was being formed by the Secretary of State for the Colonies, partly of nominees of the Medical Research Council and partly of members nominated for their knowledge of medical research in the tropics. The chairman was to be a layman, and the duties of the new body would be to advise the Secretary of State on questions affecting research in the Colonies, to advise on the administration of the Research Fund, and to form the connecting link between the developments of medical science at home and in the Colonies. A chief medical adviser to the Secretary of State for the Colonies had also recently been appointed.

The Committee further reported that it had decided to leave the question of medical organization on one side, as the new Medical Research Committee had only recently been constituted and it was desirable to allow it to examine the position fully before embarking on any definite proposals. The conference, however, recommended that it should be one of the first duties of the new Colonial Medical Research Committee to consider the establishment of a Colonial Medical Research Service. A unified research service was recommended for Colonial agriculture, and the hope was expressed that the veterinary service might be similarly organized before long.

Medical News.

THE Mackenzie Davidson Memorial Lecture for this year—the eighth of the series—will be given by Sir Humphry Rolleston, Bt., Regius Professor of Physic in the University of Cambridge. The subject will be protection and other radiological problems; it will be delivered at the house of the Royal Society of Medicine on Thursday, June 30th, at 8 p.m. [illegible] y the Röntgen Society and the [illegible] of the Royal Society of Medicine.

Sylvanus Thompson Memorial Lecture of the Röntgen Society will be given by Sir J. J. Thomson, O.M., F.R.S., on Tuesday, June 14th, at the same place at 8.30 p.m. The subject is the structure of the atom and radiation.

THE Bolingbroke Lecture of the South-West London Medical Society will be delivered by Mr. W. McAdam Eccles, M.S., F.R.C.S., in the Bolingbroke Hospital, Wandsworth Common, S.W.11, on Wednesday, June 8th, at 9 p.m. The subject will be the romance of foetal pathology. The lecture will be open to any member of the medical profession.

MR. T. W. LETCHWORTH will give a special clinical demonstration for the Fellowship of Medicine at the Royal Eye Hospital on June 9th, at 3 p.m., free to medical practitioners. The Chelsea Hospital for Women hold a two weeks' course in Gynaecology from June 8th to 21st, and an afternoon course will be provided at the Central London Ophthalmic Hospital from June 8th to 29th, with an operative class if desired. The Children's Clinic in conjunction with the National Hospital for Diseases of the Heart, the Royal National Orthopaedic Hospital, and the Royal Waterloo Hospital will hold a special course in diseases of children from June 13th to 25th. There will be an afternoon course at the Hospital for Diseases of the Skin, Blackfriars, from June 20th to July 1st; special cases of interest will be shown each Tuesday. From June 27th to July 9th the Victoria Park Hospital will provide a special course in all forms of pulmonary disease. The Fellowship of Medicine can arrange for practical courses in anaesthetics and obstetrics and for clinical assistantships in gynaecology. Copies of all syllabuses and of the *Post-Graduate Medical Journal* are obtainable from the secretary of the Fellowship, 1, Wimpole Street, W.1.

SIR DONALD MACALISTER, Bt., has been reappointed a member of the governing body of the Imperial College of Science and Technology for a further term of four years.

SIR JAMES PURVES-STEWART has been elected a foreign member of the Copenhagen Medical Society.

SIR ALFRED RICE-OXLEY, C.B.E., M.D., has, on the occasion of the visit of the French President to Great Britain, received from the French Government the decoration of the *Legion of Honour*, as an acknowledgement of the services he has rendered to France as a member of the British League of Help.

Letters, Notes, and Answers.

All communications in regard to editorial business should be addressed to **The EDITOR, British Medical Journal, British Medical Association House, Tavistock Square, W.C.1.**

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the BRITISH MEDICAL JOURNAL alone unless the contrary be stated. Correspondents who wish notice to be taken of their communications should authenticate them with their names, not necessarily for publication.

Authors desiring REPRINTS of their articles published in the BRITISH MEDICAL JOURNAL must communicate with the Financial Secretary and Business Manager, British Medical Association House, Tavistock Square, W.C.1, on receipt of proofs.

All communications with reference to ADVERTISEMENTS, as well as orders for copies of the JOURNAL, should be addressed to the Financial Secretary and Business Manager.

The **TELEPHONE NUMBERS** of the British Medical Association and the BRITISH MEDICAL JOURNAL are *MUSEUM 9861, 9862, 9863, and 9864* (internal exchange, four lines).

The **TELEGRAPHIC ADDRESSES** are:

EDITOR of the BRITISH MEDICAL JOURNAL, *Aitiology Westcent, London.*

FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements, etc.), *Articulate Westcent, London.*

MEDICAL SECRETARY. *Mediocra Westcent, London.*

The address of the Irish Office of the British Medical Association is 16, South Frederick Street, Dublin (telegrams: *Bacillus, Dublin*; telephone: 4737 Dublin), and of the Scottish Office, 6, Drumsheugh Gardens, Edinburgh (telegrams: *Associate, Edinburgh*; telephone: 4361 Central).

QUERIES AND ANSWERS.

INCOME TAX.

Motor Car Depreciation.

"H. A. M." claimed last year a deduction of £190 for replacement of car, but owing to the change from the three years' average he will only benefit in effect to the extent of one-third of that amount. The inspector of taxes has refused to make an allowance for depreciation.

*** It was decided in the case of the Caledonian Railway Company *v.* Banks that where the question of capital exhaustion was being dealt with by allowing the cost of renewals, no further allowance should be made for depreciation. As matters have turned out, it is, of course, unfortunate that our correspondent did not claim the depreciation allowance as from the first year it was obtainable; if he had done so the "renewal" allowance would have been modified and have become the statutory "obsolescence" allowance, which would not have barred the subsequent depreciation claim. In the circumstances we can only suggest that our correspondent should send to the Secretary, Inland Revenue, Somerset House, a full statement of the facts, asking that in the special circumstances the "renewal" claim should be disregarded (or looked upon as an obsolescence claim), or alternatively that he should be allowed to withdraw that claim, and should pay tax upon one-third of the £190, and thereby remove the barrier to the grant of the depreciation allowance.

Educational Fund.

"BURMAH" has formed an educational trust for the benefit of his children, providing for payments out of the funds to be made for their education, or, at the option of the trustees, to their parents for their benefit.

*** If the trust is revocable by the settlor without the consent of any other person (not being the settlor's wife), so that he can obtain for himself the beneficial enjoyment of the income, or if the period for which the income is payable to the children is less than their lives, the income must, in accordance with Sec. 20 of the Finance Act, 1922, be deemed to be the income of the settlor. In that case the income will not be regarded as the income of the children in their "own right," and "Burmah" can claim the usual statutory allowance. If the trust is not within the scope of Section 20, the amount of income expended on each child will be regarded as the income of that child (see Drummond *v.* Collins [1915], A. C. 1011), and "Burmah" can put in repayment claims thereon as natural guardian of the children. It would seem that in that case he would be unable to claim the allowance where the child's income exceeded £40, though the precise meaning attaching to the stipulation that the income shall be in the "own right" of the child may be open to doubt.

Special Repairs to House.

"H. G. P." had to purchase his house a year ago, and found it necessary to spend £140 in putting it into proper condition. His claim to deduct this amount has been refused on the ground that it was "capital" expenditure.

*** The claim which "H. G. P." can make is under *Rule* 8, No. v, Sch. A, of the Income Tax Act of 1918. He should ask the local inspector of taxes to supply him with the form of claim provided in connexion with that section, and will find the relevant clauses explained therein. It may be that there is some capital element in the total amount, representing an improvement as compared with the original property, but it seems clear that the great bulk of the expenditure is a proper subject of claim. The statutory allowance is based on an average of five years, but "H. G. P." can no doubt obtain approximate estimates of the expenditure of past years from the previous owner or his agent.

Expenses and "Earned" Relief.

"S. A. J." earned £248 last year and claimed to deduct £7 medical journals, £18 (being one-third) annual value of house, telephone £4, travelling £3, total £32, and earned income relief.

*** The assessor says the assessment for 1927–28 will be £222, apparently accepting all the deductions as claimed, except the one-third of the annual value, for which he substitutes £12. The earned income relief is not a deduction in arriving at the assessment, but is taken into account in computing the tax payable thereon. The only point which may be worth while pressing on the assessor's attention is that the deduction in respect of the use of the house should include something in respect of rates, light, and heat, and on that ground he might be urged to restore the £18 as claimed.

LETTERS, NOTES, ETC.

EARLY PARENTHOOD.

DR. LEBON, M.R.C.S. (Sarreguemines, Moselle), writes: As regards early parenthood, may I mention the following occurrence. On April 29th last I was called to a barge to see a girl who had been delivered of a child two days previously. She was 12 years old in January, and had been the victim of a rape. She had a big laceration of the perineum, which, owing to the difficulty of getting a doctor, had not been sutured. She had risen from bed on going to stool, and afterwards had a complete inversion of the uterus, which was lying in front of the vulva. I had her taken to hospital and tried in vain to reduce the inversion under anaesthesia. I renewed the attempt on the following morning, but still failed. As the girl was very anaemic and got fever, I had to give up all further manipulation. She left hospital on May 1st with her uterus still inverted, lying inside the vagina, as her parents, having in the meantime had their barge loaded, were returning to Paris, where I expect further treatment will take place. What struck me most in this case was the rapidity with which the lacerated perineum healed up without any attempt being made at restoration by suture.

PREVENTION OF TUBERCULOSIS IN GUERNSEY.

DR. H. D. BISHOP (M.O.H. for Guernsey), who recently drew attention to the very low incidence of bovine tuberculosis in that island (JOURNAL, April 16th, p. 749), now sends a comparison of the human and bovine statistics in 1910 to 1919 with those of 1924 to 1926, both years included. During the last three years 2,882 cattle were tested with tuberculin and 2 reacted, while in the previous period, out of 2,426 so tested officially, as many as 191 reacted. As regards human tuberculosis the total mortality in the first period was 478 (357 pulmonary and 121 other forms), and in the second period 123 (103 pulmonary and 20 other forms). Whereas in the earlier period the deaths of children under 5 numbered 41, representing 8.5 per cent. of the total tuberculosis mortality, in the last three years only 2 children died, the percentage having thus fallen to 1.7.

AN ALTERNATIVE TO CIRCUMCISION IN PHIMOSIS.

DR. D. R. LEWIS (Burma Medical Service) writes: As one who has performed over 500 operations [illegible] urse of nine years, while attached [illegible] the Rangoon General Hospital, B [illegible] that Dr. Whitfield's method, as mentioned on page 187 of the BRITISH MEDICAL JOURNAL of January 29th, cannot be recommended, for the following reasons, as an alternative to the usual method of circumcision: first, bleeding from the glans (a very vascular region) is apt to be troublesome, and it does not admit of the usual method of haemostasis, as it is a condition of general oozing; secondly, the narrow orifice of the prepuce cannot be readily retracted as far as the corona glandis without centripetal lacerations. When these heal there is bound to be a certain amount of constriction of the prepuce once again. From his description I understand that he relies on a good nurse to hold the baby, rather than employ an anaesthetic. This procedure certainly inflicts upon the baby unnecessary pain. It is much easier to give the baby a few whiffs of chloroform, slit the prepuce, retract it, and put a suture at each end of the cut margin—a very rapid and easy proceeding. If there is any objection to an anaesthetic the prepuce may be dilated daily, during the bath, first with a probe and then with a Spencer Wells artery forceps; the condition is generally relieved in a month's time. In the case of adults nothing gives better results than the orthodox method of circumcision.

THE STUDENT WHO SMOKES.

DR. FREDERICK BACK (Ryhope, Sunderland) writes: With reference to your commentary on Dr. Earp's "Study of the student who smokes" (May 28th, p. 973) and his hypotheses to explain why, of the students who fail to reach diploma standard, the heavy smokers are twice as numerous as the non-smokers, I think there is a tendency to confuse cause and effect. I suggest that it is not so much the fact that heavy smoking causes inefficiency as that inefficient people smoke excessively. For people with deficient mental energy and inability to concentrate it is so much easier to smoke a cigarette or chain of cigarettes than to do what is required—whether it be to make a decision, to perform some action, or to consider a subject—for one obtains the illusion you mention of doing something when, in reality, doing nothing.

MEDICAL GOLFERS.

THE medical profession has the distinction this year of supplying the amateur champion in Dr. William Tweddell of Stourbridge. Needless to say when the stage of the final round in the Amateur Championship was reached both players were very excellent golfers. It seems to be generally agreed that Dr. Tweddell owed his success, which in the end was rather hollow, to steadiness. In golf, as in many other of the affairs of men, the final event is determined rather by the faults of the rival than by the excellencies of the winner, though, as has been said, a high degree of excellence is essential. We may be allowed to congratulate Dr. Tweddell on his success.

But these high excellences would not be reached if there were not many nurseries for golfers. One of these is the Manchester and District Medical Golfers' Association, which, on May 25th, held its annual medal competition over eighteen holes. The challenge cup for the best net return was won by Dr. J. L. Bradley of Salford with a score of 71, playing from a handicap of 10. The Walter gold medal for the best scratch score was won by Dr. A. A. Smalley of Manchester with a round of 77; Dr. Bradley also secured the Walter silver medal presented for the best gross score by players with handicaps of 10 and upwards. Club prizes were won by Dr. J. Clark and Dr. J. Leech for the best net scores for holes 1 to 9 and holes 10 to 18 respectively; 122 players competed.

It will be remembered that three competitions will be played out during the Annual Meeting of the British Medical Association at Edinburgh: (1) for the Ulster and Childe Cups at Muirfield on July 21st, (2) for the Treasurer's Cup on Friday, July 22nd, at Gullane, and a ladies' competition on the morning of July 20th at Cammo.

JOHN JONES.

A [illegible] pathetic writer in the issue of the *Medical* February 2nd gives an interesting account oneer of American surgery, who was born died in 1791. After completing his studies in Philadelphia he went to Europe, where he attended the lectures of John Hunter and Percival Pott in London and of Petit Le Cat and Le Dran in Paris; he spent some time also at Edinburgh and Leyden. On his return to America he settled in New York, where his professional attainments as a surgeon and obstetrician soon procured him an extensive practice. He was the first to perform the operation of lithotomy in that city, and his fame as an operator spread throughout the middle and eastern states of America. He served with distinction in the campaign against the French in 1758 and gained the gratitude of the wounded French commander, General D'Escaux, who had been taken prisoner, for his skilful attention. When the medical school in the College of New York was founded Dr. Jones was appointed professor of surgery. After a second trip to Europe, when he renewed his acquaintance with Hunter and Pott, he published, in 1775, his *Plain Remarks upon Wounds and Fractures*, which was the first work on surgery by an American author in the United States prior to 1800, and was used as a manual of the American army surgeons during the revolutionary war. On the evacuation of Philadelphia by the British troops in 1778 he removed to that city and remained there until his death thirteen years later. He was not only the intimate friend, but was also the physician of Benjamin Franklin, whom he attended in his last illness, which was caused by renal calculus complicated by pulmonary abscess. At the time of his death Jones was physician to the Pennsylvanian Hospital, president of the Humane Society, and vice-president of the Medical College, in the formation of which he had taken an active part.

VACANCIES.

NOTIFICATIONS of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals, will be found at pages 59, 60, 61, 64, 65, and 66 of our advertisement columns, and advertisements as to partnerships, assistantships, and locumtenencies at pages 62 and 63.

A short summary of vacant posts notified in the advertisement columns appears in the *Supplement* at page 231.

A British Medical Association Lecture

ON

THE NATURE AND TREATMENT OF AURICULAR FIBRILLATION.*

BY

GEORGE J. LANGLEY, M.D.Lond., M.R.C.P.,

HONORARY PHYSICIAN, ANCOATS HOSPITAL AND SALFORD ROYAL HOSPITAL; HONORARY ASSISTANT LECTURER IN HUMAN PHYSIOLOGY, UNIVERSITY OF MANCHESTER.

THE choice of this subject has been largely determined by three considerations: (*a*) the disease is very common, (*b*) its nature is comparatively well understood, (*c*) much can be done by adequate treatment.

Intelligent treatment of the condition must depend upon an appreciation of the functional pathology of the disease, any understanding of which, in turn, connotes a familiarity with the present teachings of cardiac physiology.

Normal cardiac contraction is determined by the rhythmic generation of impulse material at the pacemaker—that mass of primitive tissue lying in the right auricle, near its junction with the superior cava, known as the sino-auricular node. Experimental proof of this does not come within the scope of this paper, but can be found elsewhere very clearly presented.[1]

The speed of the pacemaker is controlled by the interaction of (*a*) the vagus, stimulation of which slows the pacemaker, and (*b*) the sympathetic, which in turn raises the speed. The contraction impulse, having been formed in the sino-auricular node, spreads throughout the myocardium in definite orderly sequence. There is much evidence to show, and it is now generally believed, that the impulse spreads across the sheet of auricular muscle by contiguity of muscle fibre, and in no other way. Each auricular fibre is believed to hand on its stimulus to its neighbour, by which means the whole sheet is put into contraction, commencing around the great veins, and ending at the auriculo-ventricular junction.

Conduction of the contraction impulse is carried in turn to the ventricle, by means of the auriculo-ventricular node and bundle, and again in no other way, for total destruction of the bundle, by disease or experiment, prevents the auricular impulse from reaching the ventricle, and the auricular contraction is then followed by no ventricular response. The auriculo-ventricular bundle, on reaching the ventricular area, divides into right and left branches to be distributed to each ventricle respectively, by means of complex branching and arborization on the endocardial surface of the muscle, and ends in the Purkinje tissue, by means of which the impulse is believed to be handed on to the ventricular musculature.

There is, then, a complex and elaborate conduction system which carries the contraction impulse from the auricle, across the tissue of the auriculo-ventricular junction, and distributes the impulse to the ventricular muscle—an arrangement in sharp contrast to that of the auricle, where the impulse-spread, from its point of generation at the sino-auricular node, depends upon contiguity of muscle fibre only, and no conduction system exists.

It has long been known that the heart will respond to direct electrical stimulation, and if this be carried out at the apex of the auricular appendix, the speed of the heart can be raised above the speed dictated by the pacemaker; but if the speed be raised to 250 beats a minute, or thereabouts, a certain number of impulses fail to reach the ventricle. In fact, the auriculo-ventricular junctional tissue shows phenomena of fatigue before the cardiac muscle mass.

It is further known that stimulation of the vagus, particularly on the left side, is capable of reducing the conduction capacity of the bundle, even when the heart is not beating at high speed, and so a certain number of auricular impulses are prevented from reaching the ventricle—in other words, the auriculo-ventricular conduction system may be partly or completely "blocked" to auricular impulses by disease or other damage to the bundle, or by vagal stimulation. When complete block occurs, the ventricle initiates its own rhythm, which is regular, but very much slower than normal, perhaps 30 a minute, rhythm, and is usually about 32 a minute, but may be either higher or lower.

From this it follows that, when the auricle is beating at high speed, a very slight depreciation of the power to conduct possessed by the bundle will suffice to prevent a certain number of auricular impulses; in this way the ventricle may be guarded against the fatigue and overwork of a high auricular rate, and a sufficient depression of conduction would be easily brought about by vagal stimulation of a mild grade.

A great deal of experimental work has been done upon the results of high-speed direct stimulation of the auricular appendix. It is found that when the stimulation speed rises to 300 to 500 a minute the ventricular responses are usually grossly irregular in force and rhythm. In some cases cessation of stimulation is not followed by return to normal rhythm, but the events in the auricle continue exactly as if electrical stimulation were still going on.

It is believed that this phenomenon is due to the fatigue of the auricular muscle, with the result that the contraction wave runs round a ring of the muscle, probably that muscular band which embraces the orifices of the great veins. The impulse is believed to run in one direction only, and to act as the stimulus for the next auricular muscle. The condition is known as circus movement; it can only occur at high speeds, and no effective organized muscular contraction results; the capacity of the auricular cavity is not reduced by the muscular contractions, the fibres of the muscle being in a condition of continual quiver.

There is evidence to show that at speeds of about 300 a minute the path of the circus movement is practically identical, as does the path of its offsets, but when the auriculo-ventricular bundle is unable to conduct all the impulses reaching it (300), with the result that every second or every third beat only is allowed to reach the ventricle, constituting 2:1 or 3:1 block, and yielding a ventricular rate of 150 or 100 respectively. This condition is known as auricular flutter.

When, however, the speed of circus movement in the auricular muscle rises to 450 a minute or thereabouts, the path of the circuit is constantly changing, as is the path of the offset waves, the progress of both being constantly impeded by fibres still fatigued, and therefore not responsive to stimulation. The result is an irregular circus movement, constantly changing its course, and irregular offset waves which may, or may not, succeed in traversing the whole mass of the auricular muscle sheet. From this it follows that the arrival of impulses at the auriculo-ventricular junctional tissue will be both high in speed and irregular in rhythm. The consequent ventricular responses will show a high rate, and the ventricular stroke, therefore, becomes rapid, irregular and of high speed. This condition constitutes auricular fibrillation.

Our knowledge of this condition as it at present exists is due almost entirely to electro-cardiography, and any consideration of the disease must include some reference to graphic records obtained by this means. The normal electro-cardiogram demonstrates a wave due to auricular activity, which is easily recognized and identified as such. From the deviations due to ventricular activity in auricular fibrillation the auricular wave disappears, being replaced by undulations which are irregular in form and which appear and disappear in the length of the tracing. The ventricular complexes are grossly irregular in rhythm and in size, but their form remains unaltered. From this it was concluded (*a*) that no organized sequential auricular contraction takes place, (*b*) that the stimulus to ventricular contraction reaches the muscle by the usual paths—that is, the auriculo-ventricular bundle and its branches. The irregular and ever-varying undulations are attributed to the ever-changing course of the circus movement within the auricular muscle.

Clinically auricular fibrillation is too familiar to need much description: the pulse is perpetually and

* The substance of a lecture delivered before the Hastings Division, March, 1927.

irregular; the speed is usually raised, in which case all the beats do not usually reach the radial artery; there is a definite "pulse difference" between the apical rate and the radial pulse. Signs of cardiac insufficiency are usually present, but may be declared by any phase between undue pulse rise and dyspnoea on effort, up to fully developed orthopnoea and anasarca.

The grade of the disease is usually estimated by the speed of the resting pulse—in most cases the higher the speed the more the discomfort; but this is not constantly so—there is a group in which the cardiac speed is never high, but the cardiac insufficiency is marked and obvious; this, however, is the exception rather than the rule.

The rise in the cardiac speed is probably the largest factor in the heart's breakdown. There is no auricular stroke to fill the ventricle, so that any shortening of diastole must leave the ventricles inadequately filled, the muscle inadequately stretched, the ventricular stroke of poor force, and the consequent circulatory effect indifferent.

If by any means the ventricular speed can be controlled and reduced a definite sequence of events will follow: the prolongation of diastole will permit of adequate ventricular filling; the ventricular muscle fibres will be thereby sufficiently lengthened to yield a contraction of good force; the ventricular muscle will receive sufficient rest for full recovery after each contraction; the general nutritional state of the heart muscle by way of the coronary arteries will be materially improved.

The treatment of auricular fibrillation may be considered under two heads: (1) the control of the high ventricular speed with consequent general improvement of the circulation, and (2) the re-establishment of a normal cardiac rhythm.

For the control of ventricular speed drugs of the digitalis group have enjoyed a very long reputation, but the large number of preparations at present offered to the profession would argue rather that the results obtained are by no means always satisfactory, and a review of the effect of the drugs under scientific observation may not be out of place. The criterion of action of the drug must be ventricular slowing, for that is the most usual result aimed at in administration.

In judging of the effects of the drug three factors must obviously be considered: (*a*) the dose given, (*b*) the preparation used, and (*c*) the potency of the preparation. At the outset, for purposes of careful clinical observation, it becomes necessary to limit investigation to one preparation of one drug, and the vast bulk of the work has been done with tincture of digitalis. The use of other preparations of other drugs will not give easily comparable results. Even so, the potency of various tinctures has been shown to vary sufficiently to make comparisons difficult, and preparations are now frequently labelled "standardized by physiological assay" in an attempt to overcome this difficulty. Without entering into the technicalities of physiological tests of this sort many methods have been tried, but it must be remembered that effects produced in the artificially perfused heart do not necessarily represent results obtainable under clinical conditions, and that injection methods allow the whole contents of the tincture to act, whereas gastro-intestinal absorption may only be possible to certain compounds in the galenical preparation.

A recent method which we owe to the Pharmaceutical Society's laboratories is to hold a standard powdered leaf, and from this to make a tincture by a standard method, to compare the results obtained by experiment with this standard tincture to results obtained under identical conditions with the unknown tincture to be tested, and to express the result in percentage potency of the standard. Even so, it is tenable that the result attained must be corrected by observation under clinical conditions, as matters at present stand.

The dose of the drug, the preparation used, and the potency of the preparation all having been fixed, there yet remains another factor. It has been clearly recognized ever since Mackenzie's early work on the irregular pulse that the results obtained by digitalis administration in auricular fibrillation are totally different from the results obtainable by giving the drug to the patients with high speed pulses from any other cause,[2] the one possib exception being auricular flutter.

In using the ordinary pharmacopoeial dose of the dr it is well known that immediate results are not to be look for. The drug is said to be dangerous because its acti is cumulative, and, under ordinary dosage, benefit can expected after about a week. It would appear from th that the drug must be allowed to cumulate in the bod until a certain degree of concentration or saturation h been attained. On the other hand, it would seem somewh illogical to induce the saturation point slowly while t patient is suffering all the distress and discomfort complete cardiac failure. Mackenzie has shown that t full effect of the drug can be attained by giving the tinc ture at the rate of a drachm a day,[3] and that the tim occupied is five to seven days.

The matter was carried considerably further b *Eggleston,*[4] who worked with a tincture which had bee standardized by the Hatcher and Brody cat unit method The minimal lethal dose per kilo of body weight of cat ha been carefully determined, and the tincture was used b Eggleston in the treatment of auricular fibrillation, th action of the drug being carefully watched both clinicall and graphically. By this means it was found that on cat unit was usually represented by one cubic centimetr of a good-class active tincture, and that the full thera peutic effect could be attained clinically by the administra tion of a dose calculated on the basis of 0.1 c.cm. per lb body weight of the patient. This dose was administered i three portions extending over a period of eight to twelv hours.

This is now known as Eggleston's method of massive digitalis administration. Toxic results do not follow, as the dose is carefully calculated to fall short of the toxic amount. The method has permitted of a much closer and more satisfactory study of digitalis effects. Robinson[5] has shown that some therapeutic effect is recognizable within two to four hours after administration, and that the full therapeutic effect is attained usually at the end of six hours. Pardee[6] has estimated that the duration of the good effect is from six to ten days, and that the rate of elimination is about 25 minims a day.

Given by this method of massive dose, therapeutic results are very rapidly attained, but it is imperative that the potency of the tincture used be fully known.

A modification of this method has been in use in my hospital service—the full calculated dose at the rate of 0.1 c.cm. per lb. body weight of patient has been given as a haustus made up to ʒ iij with sodium bicarbonate, aromatic spirits of ammonia, and chloroform water. Electro-cardiograms have been taken before and every two hours after administration, until five or six tracings have been made. With the particular tincture used, and at this rate of calculation, a full therapeutic effect was not frequently attained, and the tincture would therefore appear to be somewhat weaker than that used by Eggleston. The T-wave of the electro-cardiogram in Lead II was not usually inverted even at the end of eight hours, but the slowing effect was well marked in nearly all cases within that time. Toxic effects did not occur except in one case; the nature of the changes in this case are not understood, but the pulse rose considerably in frequency and the electro-cardiogram became profoundly altered, suggesting some severe toxic effect upon the heart, but nausea and vomiting did not manifest themselves.[7]

Altogether 54 cases have been treated by this method. The average dose of the tincture administered was 13 c.cm.; the average pulse speed before administration was 140, whereas eight hours later the average speed was 91. The average duration of satisfactory effect was six days, so that small routine doses of the tincture were usually necessary at the end of a week. Vomiting occurred in two cases, both of which had been given a dose calculated on a basis of 0.15 c.cm. per lb. body weight, a rate which was too high for the tincture used.

That the effect of digitalis in auricular fibrillation stands by itself, and has no counterpart when the drug is administered to hearts at normal rhythm, is clearly shown in the following table, in which it will be noticed

that no slowing of the pulse takes place as the result of exhibition of the calculated dose.

	Age.	Dose.	Before.	After.
Normal rhythm.				
Wy.; F.	48	11.3 c.cm.	132	132

The clinical indications for this method of administration of the drug would appear to be clear—a large dose is only indicated to save time and suffering, and therefore only in the presence of cardiac breakdown of the major type, with dyspnœa to the point of distress, or marked anasarca.

Under such conditions the pulse speed, or rather the apical cardiac rate, is materially raised in most cases, and it is in these that the most brilliant demonstrable results are attained. At the same time the method has been used where cardiac failure with fibrillation is present in spite of an apical rate of under 100 a minute, and under these conditions the results are just as satisfactory and no untoward effects have occurred.

In a considerable proportion of cases the patient has already been given digitalis, or members of that therapeutic group in some form or other, and toxic effects are certain to result if a large dose be administered when the patient is already to some extent under the influence of the drug. In view of the calculated excretory rate of 25 minims a day, and the duration of effect as seven days,[6] some estimate of the therapeutic position is best arrived at by calculating the excess of tincture received in the previous week over (175 ♏ or) ʒ iij, and deducting this from the therapeutic dose calculated at 0.1 c.cm. per lb. body weight.

A very real difficulty, however, remains with regard to the potency of the tincture which is actually administered to the patient; provided the preparation is in constant use and under careful clinical criticism, the difficulty is small, but this is only likely to be so in hospital service. At the same time, the calculation at the rate given above is sufficiently far removed from the toxic dose to permit of 25 per cent. increase in potency of any tincture over the normal, without producing any severe toxic signs.[4] And moreover, since vomiting is an early toxic effect, it will probably mechanically protect the patient from further absorption, and thus from further damage. It may be remarked in passing that preparations of digitalis which cannot produce vomiting are likely to be inert in all other respects, and that the vomiting itself is a valuable indication. Want of response to digitalis therapy in auricular fibrillation is not a tenable statement, unless and until vomiting has been caused by the drug. It has been remarked, however, that the vomiting caused by a massive dose of digitalis differs materially from that which arises in the course of prolonged and continuous administration of the drug. Of the two cases in this series in which vomiting occurred one vomited twice within three hours, and the other four times within five hours; in both cases no further gastric disturbance was observed. This differs widely from the results of long-continued digitalis administration, in which, when vomiting starts, it is most likely to continue for four days, with much gastric disturbance.

As already stated, the administration of a massive dose of digitalis is only advocated as a measure of urgency, to overcome the suffering and discomfort always associated with complete cardiac breakdown. This having b accomplished, there yet remains the future condition the patient to be considered and treated. The benefic effects of a massive dose usually begin to disappear the end of six or seven days, the indication being distinct rise in the pulse frequency. All the cases this series have remained at rest in bed for at least a we after the initial large dose; usually at the end of th time the pulse has returned to 100 a minute or the abouts. The patient is then allowed up for a short ti each day, and is started on tincture of digitalis, 5 mini three times daily. It is usually necessary to increase t amount up to 10 minims thrice daily, in order to maint the pulse at 90 a minute after half an hour's rest in t recumbent position immediately after the mid-day me Lewis has pointed out that in auricular fibrillation t pulse speed may be set to a nicety by means of digitali the speed and conditions quoted above are the ones wh are aimed at.

Experience goes to show that one large factor in t causation of cardiac breakdown in auricular fibrillation the cessation of digitalis dosage. This has been repeate emphasized in the past,[9] and it is probably true that enter upon digitalis life is much the same as to en upon catheter life—continuance of the usage is imperati The bugbear of "cumulative effect" still appears to sw the mind of the profession, but, as has already been point out, the drug is probably inactive until a certain deg of cumulation has taken place, and it is only the ma tenance of this cumulative effect that will save the patie from disaster.

The precise method of action of digitalis yet rema unproven, but for purposes of therapeutic judgement it wise to regard the drug as affecting the vagus.[10] Sufficient drug must be used to stimulate the vagus up a point where the degree of auriculo-ventricular block just sufficient to allow impulses to pass at about norn speed from auricle to ventricle; when the block exceeds t in degree, and particularly when coupled beats, givi bigeminy, arise, the vagus is being overstimulated a vomiting is near.

An estimate of the daily excretory loss of the drug c be formed, as Pardee has pointed out, by determining t average daily dose necessary to maintain a certain clini effect over a period of time. In the out-patient cli the usual dose necessary for patients up and about a following such light occupations as auricular fibrillati will generally permit is 30 minims daily, and it is giv in three daily doses. Over a large series of cases it found that smaller doses require periodic increase, wh larger doses require periodic decrease.

The general supervision and treatment of these patie calls for careful and frequent examination, and consta small adjustments of their lives, requiring experience a worldly wisdom, but the results attained are very sat factory. No effect whatever must be looked for upon t irregularity of the pulse under digitalis treatment; t rhythm will remain as chaotically irregular as ever und correct dosage, but the pulse difference (the difference speed between apical and radial counts) will be materia reduced, and in many cases will disappear altogether.

Any statistical study of the results of auricular fibril tion is rendered difficult by the usually long duration the condition, and also by the fact that it may in so cases be "spasmodic," and occur in attacks of sudd onset, variable duration, and spontaneous disappearanc

Of 133 cases studied recently the sex incidence w equal, but a history of rheumatic origin was obtained 50 per cent. of females, and in only 30 per cent. of mal The additional frequency of mitral stenosis in women, an still further, the frequency of fibrillation as the third sta of stenosis, might have been expected to raise the fema percentage much higher. The frequency of auricul fibrillation in chronic interstitial nephritis, bronchitis, a as a part of general senile changes could not be direct estimated. The group caused by exophthalmic goit accounted for only 11 cases, 5 male and 6 female, but th all appear to have responded indifferently to digital Parturition appeared to have been the immediate cause 3 cases, 1 of which died and 2 responded very badly

treatment. The importance of this group can hardly be overestimated, more particularly in view of a recent paper by Robinson,[12] in which 13 deaths occurred as the result of parturition in the 16 cases studied. Hemiplegia occurred in 5 cases, and death took place while under treatment in 14 cases, but this cannot represent the real mortality, for most of the patients attended the out-patient clinic, and such are frequently lost sight of, and cannot be traced. Poor results of treatment were obtained in 19 cases, presumably on account of extensive myocardial damage, although this was by no means always demonstrable by any diagnostic method—for example, in the exophthalmic goitre group. No digitalis was given to 14 patients, there being little or no sign of cardiac insufficiency.

Cases of typical auricular fibrillation are frequently reported in which the pulse speed is at, or about, 80 a minute, and, although grossly irregular, yet the pulse rise on effort is not great and the capacity of the patient for work is sufficiently high to allow him to continue fairly laborious occupations. It was in this group that no digitalis was used.

In a small number of cases there is a real difficulty in the administration of any digitalis, because the passive congestion of cardiac failure has itself already caused vomiting. It was thought that if the active principle of the drug were a glucoside, and glucose could be readily absorbed by the rectum, it might be possible to administer a massive dose by that route. The calculated massive dose of the tincture was so administered in two cases, but, although the enema was well retained, no effect upon the pulse speed was observed. This result corresponds well with results obtained by the administration of glucose by the rectum, in which no rise in blood sugar could be found, and it is probable that no absorption takes place.[13]

The treatment of auricular fibrillation by digitalis or its allies does not aim at the correction of the abnormal rhythm, nor at the cure of the causative condition, and no such result is attained. The drug is merely a means, and a very valuable one, for defending the ventricle adequately against the onslaught of auricular stimuli of high frequency, by which means the ventricle is given adequate diastole for reasonable filling and reasonable rest; apart from this, complete cardiac breakdown is both proximate and inevitable.

The principle underlying the quinidine treatment of auricular fibrillation is, of course, entirely different. Here a definite attempt is made to restore the normal cardiac rhythm. This line of treatment is not in the least applicable to patients showing any serious grade of cardiac insufficiency. In the majority of cases a preliminary course of digitalis is necessary to re-establish the circulatory balance, and it is usually believed that the high speed pulse is a definite contraindication to quinidine.

The question of potency in the preparation does not arise, since it is a crystalline substance of high purity, and is readily soluble in acid solution in the same way and much to the same degree as quinine.

The success of the drug turns upon the fact that the continuance of circus movement within the auricular muscle depends upon three factors—the length of the circuit, the impulse conduction time, and the refractory period of the muscle.[14] Any considerable change in one or other of these three factors would terminate the circus movement, and quinidine has been shown to prolong the refractory period of the muscle to an extent sufficient to bring the circus movement to an end. Immediately this occurs the cardiac pacemaker comes into action, normal rhythm is re-established, and the auricular muscle performs a definite systole, thus once more filling the ventricle normally. The fact remains, however, that the primary cause of the state of fibrillation still continues, and that, therefore, relapse is almost inevitable ultimately.

It is generally believed that almost all cases of fibrillation can be forced into normal rhythm, provided quinidine be given over a sufficient length of time and in sufficient concentration, but my own experience is that when large doses are required normal rhythm does not remain long.

The present routine in my service is, in the first place, to reduce the pulse frequency to between 80 and 100 a minute while at rest in bed. Quinidine sulphate is then given in 6-grain doses every two hours for five doses—that is, a maximum of 30 grains. Electro-cardiograms are taken before every dose, and examined, so that, should normal rhythm become re-established, no further quinidine is given that day. The next day the patient is given a mixture containing 1-grain doses of quinidine. This is taken three times a day, and is continued for six to twelve weeks. In my opinion quinidine administration is difficult, and probably should not be attempted, in the absence of electro-cardiographic control. Signs of toxic effect upon the heart are fairly frequent, even with the strictly limited dose detailed above, and although no untoward event has occurred, yet the rise in speed can be very alarming, even when adequate tracings are made every two hours.

In successful cases—those in which normal pacemaker rhythm becomes re-established—the patients themselves very generally recognize the difference, for the continuous palpitation of fibrillation completely disappears. Those that have been regularized more than once can frequently tell the precise moment at which the change from one rhythm to another has occurred.

In spite of the enormous theoretical benefit that should accrue when a fibrillating auricle again resumes a correctly timed and regular contraction, yet a considerable number of regularized auricular fibrillation patients consider themselves no better than they were when under adequate digitalis control. On the other hand, another group of patients will return immediately for further regularization whenever fibrillation recurs, because they recognize very clearly that their capacity for effort is very much higher under pacemaker rhythm than it can ever be during fibrillation.

However brilliant the results of quinidine administration may be in a small proportion of patients, it yet remains obvious that the routine treatment of auricular fibrillation must be carried out with digitalis.

This paper will have attained its object if it helps in any way towards an appreciation of the underlying processes of fibrillation, the objective of digitalis treatment, and, above all, an adequacy of dosage.

Remarks ON THE CAUSATION OF ANGINA PECTORIS:

WITH A REPORT OF THE RESULTS OF SOME EXPERIMENTAL AORTIC LESIONS.

BY

R. CUNLIFFE SHAW, F.R.C.S.,

MANCHESTER.

THE failure of medicine to supply a consistently satisfactory method of treatment for angina pectoris renders necessary the careful investigation of any new procedure for which a claim of cure, or even amelioration of the symptoms, has been advanced. Such is presented by the introduction of surgery into this field, as instanced by the successful operations of Jonnesco, or of Coffey and Brown. On the correctness of the theoretical view of the causal lesion depends the justification for surgical intervention; if it be in the heart or aorta it is beyond the present scope of such procedure, but if the anginal syndrome is attributable to a nerve lesion or depends on the integrity of a nerve path, this line of treatment merits more serious consideration.

Any explanation must take into consideration two essential factors—the neurological element as shown by the operative results, and the cardio-aortic lesions as evidenced by their frequency. Theories that view angina as a neuralgia or paroxysmal neurosis are too nebulous to carry conviction; to disregard the almost constant vascular lesions is to ignore one of the principal features of this condition. On the other hand, to attribute the disease solely to derangement of heart action due to myocardial incoordination or insufficiency is to disregard the very definite neurological factor and the results of surgery. Hence the necessity for some link which will combine these two factors in an interpretation of the disease. With this objective in view, I carried out an experimental investigation the results of which form the basis of the theory of this paper. The details of this have been reported elsewhere;[1] it will suffice here to give a summary of the work.

Following up a line of thought suggested by the work of Todd and Stopford, who have shown that irritation of the peripheral nerves by injury or anatomical abnormalities such as cervical rib produces vascular degeneration in the distribution of the affected nerve, it was decided to apply similar conditions experimentally to the cardio-aortic nerves. For this purpose rabbits were selected and a number of experiments performed in which these nerves in the neck were subjected to chronic irritation, the animals being killed after intervals of several months. It was found that approximately 80 per cent. of the autopsies exhibited inflammatory plaques in the first part of the aorta, either near the valves or near the commencement of the innominate artery; further, the results showed that different stages of aortitis were represented, from early proliferation of the intima to the formation of atheromatous abscesses and the sloughing of the vessel wall in one case and to a diffuse aneurysmal dilatation in another. Generally speaking, the most advanced stages were observed in those animals that had lived the longest after operation. The most frequent lesion was a fairly well defined plaque due to proliferation of the intima and media; there was an increase of cellular elements and hypertrophy of elastic and muscle tissues, and frequently a slight fatty change in the intima. These experiments were controlled by a number of necropsies on rabbits that had been operated on under general anaesthesia with other objects, and had been kept under like conditions. In none of these cases were similar lesions found. In the heart, changes chiefly of a fatty nature were commonly present, but in a few instances there were other degenerative changes. The value of this latter evidence is unfortunately affected by the frequency of fatty degeneration in normal hutch-fed rabbits. In all the *post-mortem* examinations it was noted that the nerves operated on were firmly embedded in a small mass of scar tissue which it was the objective to produce, so as to have a slowly-acting irritant increasing in its severity and thus to simulate the human lesions.

Manouélian has experimentally produced atheromatous plaques in the pulmonary artery and in the abdominal aorta by removal of the nerve supply, whilst the experimental results mentioned above prove that disturbance of the normal conductivity in the cardio-aortic nerves likewise results in pathological lesions, at first slight, but later gross, of the aorta and probably in the heart, though the evidence for the latter is not quite conclusive. Here, then, we have a connecting link between the nervous system and the cardio-aortic lesions. The hypothesis may now be stated: that angina pectoris is a group of symptoms primarily invoked by a nervous lesion, located either in the upper dorsal or lower cervical cord, its associated ganglia or their connexions, and that such lesion secondarily invokes inflammatory and degenerative reactions in the aorta and possibly the heart. These become progressively worse, thereby inducing a vicious cycle of irritation, which on the principles of induction and facilitation of synaptic resistance produces hypersensitivity of the sensorimotor mechanism of the heart, especially the vagal element, commonly resulting in sudden death in severe cases.

From the surgical standpoint the compatibility of this hypothesis with the results obtained is sufficiently obv That Jonnesco's operation has gained the most su judged purely on its effect on the angina, is re understandable if the lesion is in the area supp that Coffey and Brown's operation alleviates but not cure may likewise be explained, in that the channels for the conduction of irritant impulses tha eliminated the more likelihood is there of the dimin of the severity of the symptoms; a cure in this way not, however, be expected.

Some of the corroborative clinical evidence for hypothesis may be briefly stated.

I.

In a number of cases the angina is accompanie very definite signs of disturbance of function in the so nerves, more especially in the left arm, affecting the m sensory, and trophic elements. In the first-named cat come paresis of arm or hand muscles, or transitory para as in the case reported by Bretschneider, or those tioned by Allbutt, of increased myotatic irritability exaggeration of reflexes such as the supination and t jerks. Under the sensory heading hyperaesthesia, anal and anaesthesia have all been reported. In one striking case recorded by Gibson all three sensory ch occurred in the left arm, and, what is more noteww in the order which has been described by Stopfo characteristic of the syndrome of nerve compre Under the last-named group muscle wasting, necro the superficial layers of the dermis in the hand as rep by Salvini, herpetiform irruptions, and even lichen p have been found in anginal cases. With regard to l an especially interesting case which I saw may be l mentioned, for it illustrates not only this conditio the occurrence of strongly neuritic prodromal sym in a classical case of angina.

A lady, aged 43, in an important executive position at with much anxiety, complained in 1915 of pain and weakn the left arm; in 1919 there was severe pain on the same side ... arm; about March, 1920, s tachycardia, and flatulence; sixth dorsal areas in the lef followed by an outbreak of herpes. At this time the patie subjected to increased mental strain and worry. In May same year, following a long and tiring motor drive, pain o in the left arm, and following dinner that evening she was with a sudden sense of constriction in the left side of the followed by an inspiratory gasp, and then a severe stab-lik in the back of the chest, which was in turn followed by a t and tightening sensation over the heart. The patient was d forward, unable to move or speak, and obsessed with the death.

II.

In many cases, as discussed by Head, there is a di tion of the symptoms, crises of peripheral neuritic or of intrathoracic pain and sensations of cardiac oppr alternating with classical attacks of angina. If a lesion be the cause it is conceivable that irritation particular group of fibres or cells might occur, occasi producing either peripheral or visceral symptoms, w if all neuritic symptoms be the secondary effects of a aortic disturbance it is difficult to see why at time a lesion does not manifest itself clinically whe supposed secondary effects, the pain crises in s nerves, are very much in evidence.

III.

A nerve lesion located in the region presumed i theory might be expected to exhibit clinical signs of tion characteristic of the sympathetic—as, for exam the vasomotor fibres, on the sweat excretory mech on the ocular path, or, again, on the cardiac accele mechanism. With respect to the latter it must be r bered that the rate of the heart beat must represe algebraic sum of two antagonistic influences—the pathetic and the vagus, with the latter normally pr nating. The close association in the medulla betwe accelerator and inhibitory centres might conceivably in irritative impulses from the cord or ganglionic stimulating either centre or both to equivalent d resulting in acceleration, inhibition, or no change rate of the heart beat. The severer the attack, th sumed great degree of irritation, the more probable

[1] *Quart. Journ. of Med.*, vol. 19, No. 74, 1925.

spread of the stimulus to both controlling centres, preventing change or even slightly augmenting the vagal inhibition. The same may be said of the vasomotor phenomena; the reciprocal innervation of vascular areas and their intimate adjustment by the principal and subsidiary centres in the medulla and lateral horn of the spinal cord would tend to prevent great extremes of vascular tone. In some cases the great variations in the volume flow of blood through the arms during a crisis, especially in the left, are well shown by plethysmographic tracings. With respect to the other nerve paths excessive sweat excretions and pupillary changes have been reported; these were specially noteworthy in Gibson's case, where the left pupil dilated and the eye became more prominent during an attack; and in the case Allbutt records, where "profuse sweating always preceded the attacks by half an hour." In several instances increased tonicity of the skeletal muscles is recorded; in Hunter's the attacks commenced with rigidity of the facial muscles. Alterations in muscle tone are especially interesting in view of the recent evidence relating this with the nerve terminals of Boeke and Agduhr, which are sympathetic in origin, possessing trophic cells in the sympathetic ganglion of the lateral chain.

IV.

Certain other concomitant symptoms are distinctly favourable to a neurological theory. The sense of cardiac oppression common to anginal attacks is reported by Lauder Brunton as being voluntarily produced in the case of Professor Cernak, who could compress his vagus against a cervical exostosis, when he experienced a sense of "*Beklemmung*" (oppression) in the chest. Several instances of pathological compression are recorded by Skoda, Allbutt, and others. Closely allied to this symptom is the sense of impending dissolution, the angor animi. Its affinity to angina has been noted by writers who support the aortic theory, and the rarity of this psychical phenomenon in other heart conditions, accompanied by lesions just as grave, is a singular fact. Mott records a case of cerebral tumour, accompanied by this feeling; does not this suggest that its anginal incidence is the result of irritation of higher cerebral centres?

Salivation is another symptom frequently encountered. The secretion of an abundant watery saliva is dependent on impulses passing through the chorda tympani, the geniculate ganglion, pars intermedia, to the nucleus of the fasciculus solitarius; there is a connexion thence with the upper part of the glosso-pharyngeal vago-accessory nucleus. The occurrence of salivation is readily intelligible if we suppose a nervous lesion in the lower cervical region sending irritant impulses to the medullary sympathetic and vagal centres. The occurrence of gastric disturbance is likewise to be expected in many cases; just as it has been shown that different sympathetic paths are stimulated so also are the vagal. Again, the relief of gastric distension by the passage of an oesophageal tube, as Verdon practised, would tend to prevent a vicious cycle of increased irritation from that region.

V.

The association of angina with mental irritation is a well known fact; the effects of nerve irritation on non-nervous structures have been described—what might be the effects of irritant impulses from the cerebrum on similar structures or on lower nerve-centres?

VI.

Lastly, two cases may be mentioned illustrative of the relation between the nerves and the heart here propounded. In the first, reported by Tenier, a man sustained injury to the cervical spine, spondylo-arthritis developed and coincidently the right heart became dilated, there was arrhythmia and a loud systolic murmur, all of which disappeared as the vertebral trouble subsided. In the second case, reported by Klippel, a man developed cyphoscoliosis, and gradually there came on complete hemiparesis of the left side, with sweating and dilatation of the capillaries, and loss of thermal sense on the right side of the body. During these changes there were four definite attacks of angina distributed over two years.

CONCLUSIONS.

Evidence has been given from the clinical side in which it has been shown that there are reasons for supposing the anginal syndrome to be principally the sum of irritation of several nervous paths, and that certain features indicate direct organic interference with those paths. From experimental pathology it has been found that a primary irritation of the cardio-aortic nerves is capable of exciting in the region they supply pathological lesions identical with those commonly found in angina. Finally, pioneer work in surgery has proved that complete extirpation of the left cardio-aortic sympathetic nerve and connexions may abolish the anginal syndrome.

It is therefore concluded that angina pectoris is probably due to a nervous lesion located in the region of the lower cervical or upper dorsal cord, the associated ganglia or their connexions, exciting secondary pathological changes in the cardio-aortic region; and lastly, that surgical intervention in suitable cases is justifiable from the theoretical standpoint.

CHRONIC RHEUMATISM.*

BY

A. T. TODD, M.B.ED., M.R.C.P.LOND.,

HONORARY ASSISTANT PHYSICIAN, BRISTOL ROYAL INFIRMARY; DEMONSTRATOR OF PATHOLOGY, BRISTOL UNIVERSITY.

By chronic rheumatism is meant the presence of aching pains and stiffness affected by changes of the weather. Excluding the subacute arthritis of young adults and children, with sudden onset, some pyrexia, and, as a rule, an obvious septic focus, and also the relatively rare cases of primary myositis and neuritis, we are left with three clinical types: (1) arthritic, osteo-arthritic, or rheumatoid, dominant; (2) muscular, with latent arthritis, commonly termed fibrositis; (3) neuritic, with latent arthritis, commonly termed neuritis.

Transitions are presented from case to case, and in any given case, so that they may be considered to be different manifestations of one disease. Exception may be taken to this classification—neuritis is regarded as a common disease. The *non-arthritic* neuritis is eased by rest and made worse by warmth and congestion; in secondary, or arthritic, neuritis the converse holds. Nine of every ten cases diagnosed as neuritis show latent arthritis. The same is true of the muscular type, and in both the most effective treatment is directed to the joints. In an arthritic case examination will frequently show that some of the joints are of the rheumatoid and others of the osteo-arthritic type.

It may occur *in young subjects*; patients aged 17 and 19 are being treated at present. It is more common in women, probably on account of their larger infectable surface and more rapid endocrine upheavals. A family history of gout or rheumatism is frequent. In the personal history contact with lead, hard work, exposure, poverty diets, humidity, and damp houses appear important, but are inconstant and therefore have a secondary value.

* A paper read before the West Dorset Division.

Basal causes are (*a*) some toxin or toxic substance acting adversely on the joint and its surroundings; (*b*) some factor permitting selective action on these structures.

The Toxic Factor.

This at present is thought to be sepsis. Such a cause is seen in gonorrhoea; a case recently seen, diagnosed as and completely simulating rheumatoid arthritis, very rapidly cleared up when the infection was eliminated. In Malta fever arthritis and spondylitis very similar to those of rheumatism occur[1] and disappear when the sepsis is conquered. Experimentally 58 per cent. of rabbits infected with streptococci from various sources showed a varying type of arthritis.[2]

The facts that little sepsis may be found at the examination and that removal of sepsis is often disappointing, have been taken as evidence against its importance. It may be that the sepsis has done its work. Cases seldom recover if sepsis is not removed; when a patient fails to make good progress it is well to look again for a missed focus. Evidence for the presence of sepsis when none is apparent is elicited by an Arneth count of the blood.

Septic foci are most commonly found in the mouth, especially dental. The area of the teeth sockets is estimated to be about 20 square inches. In many of the patients a large proportion of this is a suppurating surface. Judging from the great pressure required to squeeze pus from a socket; it is not wise to expect drainage to be perfect, and even if it were, we cannot say that swallowed pus is innocuous. Apical infection may be present without much periodontitis, and may be missed by *x* rays if there is no rarefying osteitis.[3] In chronic rheumatism a suspicious tooth should not be given the benefit of the doubt. The nose and accessory sinuses are not uncommonly infected. The genito-urinary system is frequently involved, and pyelocystitis, endocervicitis, etc., with leucorrhoea in women and prostatitis in men, are common. Cholecystitis is not uncommon. Gastro-enteric infection occurs in many cases. A large proportion show hypochlorhydria or achlorhydria and infection of the small bowel. The opposite condition, "hyperchlorhydria" from faulty pyloric action, with subsequent hurried gastric evacuation, is also common. From these and reflex hepatic causes dyspepsia is almost constant in elderly patients, and extracted molars must be replaced or the dyspepsia is aggravated. Evidence of the bowel infection is to be obtained from bacteriological examination of the stools and from the amount of indican and urobilin in the urine. Unfortunately multiple foci are the rule rather than the exception.

The Selective Mechanism.

Here we are dealing with theories as well as facts.

The work of Rosenow[3] showing that an organism from a certain focus will usually attack that same focus in the experimental animal is suggestive. Probably the affinity is chemical, like that of tetanus toxin for the nervous system, and the toxin depresses joint defence and regeneration. The functional resemblance of the periodontal and synovial membrane is significant. There may be local anaphylaxis; arthritis has been produced experimentally in this way.[4] The hereditary influence is so marked that the possibility of functionally hypoplastic joints is raised. Injury is occasionally a localizing factor.

A factor of apparent importance, not previously noted, as far as my knowledge goes, is the occurrence of some vasomotor disturbance preceding the onset of the arthritis. Though proof is lacking, it may well be that variations in the nutrition of the joint and lowering of defence and repair are thus produced. The frequency of the condition at the menopause and the occurrence of painful cramps in the neuritic type are significant. In fully 50 per cent. of the total cases vaso-neuroses, chiefly of the Raynaud type, are found. The patients have suffered from "dead fingers" in cold weather. Less commonly there has been local asphyxia. Three of my patients had been diagnosed as cases of true Raynaud's disease some years previously. In two cases the opposite condition, a degree of erythromelalgia followed by coldness, was found. As these symptoms usually disappear before the onset of the rheumatism their occurrence is not often volunteered.

best guide. Some take cider without harm, others of the same type find that pain is increased. If it can be taken *without increase of pain, a little sound wine appears to* help digestion and nutrition.

Attention to the secretory activity of the stomach is usually necessary, but must vary with the anomaly found. The flatulent, vague dyspepsia of the hepatic improves with the liver-sparing diet. Where there is achlorhydria or marked hypochlorhydria a mixture of hydrochloric and phosphoric acids with food should be given; for complete achlorhydria in an average-sized adult, 20 minims, rapidly increased to 1 drachm, of each in a tumbler of water flavoured with sugar and orange juice, should be sipped with each full meal. In the rapid emptying type belladonna before, or a little olive oil with, meals is helpful.

Drug Treatment.

Laxatives are frequently needed. The diet, supplemented by agar-fig and prune jellies, helps. Abdominal massage along the colon, applied by means of a weighted croquet ball, is useful. Sulphur confection (though sulphur by the mouth has no action on carbohydrate metabolism), podophyllin, calomel, and blue pill all are useful in stimulating bile flow.

Sedatives are often needed, especially at the menopause, when bromides are indicated. Salicylates associated with podophyllin, and administered at the beginning of the *meal, often appear to ease the pains of rheumatism; unless* given at this time they may intensify the dyspepsia. Phosphorus, given as phosphoric acid when the gastric acidity permits, has a sedative action; it may also be given as phosphorus pills in 1/100 grain doses thrice daily, but not for too long, as it has a marked toxic action on the liver. The same is true of phenacetin.

Thyroid extract often helps, but should be reserved for the cases which show increasing adiposity, constipation, and a relative lymphocytosis. It acts as a stimulus to metabolism and indirectly increases repair and immunity processes. The thyroid-manganese compound would appear to act in this way, though the combination of the two probably reduces the activity of both—as thyroid is often given in far too large doses, the reduction may well account for the good results reported. Manganese acts by increasing immunity responses, especially antibody formation.[8] It may be given by injection of the colloid, or as permanganate in lavages and in vaginal douches in cases presenting leucorrhoea. The value of iodine is well recognized; it appears to give the best results in the neuritic type, especially in younger subjects. It may be given as the French tincture, without iodide, 5 to 15 drops in milk, after food. Caffeine tri-iodide in freshly made pills of 2½ grains may be used; the caffeine may act as a vasodilator. Iodine may also be given as lipiodol injected deeply once weekly in doses of 7 minims, increasing to 30; many patients improve rapidly, but the effects do not often last long. There is little reaction to lipiodol. If it is well warmed and poured into the barrel of the syringe it is easy to inject. Severe old-standing cases of the arthritic type do not respond to iodine.

Protein Therapy.

Vaccines should be reserved for the recent cases in younger subjects with marked septic foci. Vaccines may be combined with manganese, for the reason given above. In the old-standing cases non-specific protein therapy gives better results. In cases of this kind, where pain, rather than limitation of movement, is the complaint, good results frequently follow intramuscular injections of foreign protein—caseosan, novoprotein, or any of the many kinds on the market. The larger the dose and the greater the reaction, the better the result.

In the rheumatoid type intravenous protein treatment affords a large *proportion of rapid results, and should be* given at the outset. Any vaccine, but preferably an old one consisting of *B. coli* or the *typhosus* group, may be used. It is well to commence with a dose of 50 million, and increase or diminish as needed to obtain pyrexia of about 101°. As the course proceeds an increase of the dose is usually necessary. The reaction is unpleasant, but the patient may be consoled by being told that the result is proportional to the degree of reaction. Salicylates are *useful in the control of the reaction.*

Sulphur Treatment.

Sulphur injections are of special help in the old-standing cases of the osteo-arthritic type with pain and marked limitation of movement. It may give good results in other *types, however. The treatment should not be used in feeble* or very querulous patients. If pain is not marked it should only be given if there is an earnest desire for increase of motility.

The injection should be given deeply into the trunk muscles or thigh. The best form is the sulpholein of Egger of Buda, or a saturated solution of sulphur in poppy-seed oil, or any non-mineral thin oil, may be made and sterilized by heat. The initial dose should be about 6 minims, and the early reactions, usually severe, noted. Three days after the reaction has passed should be allowed before repeating injection, and, as reaction permits, the amount should be rapidly increased until the patient is receiving from 30 to 45 minims. I usually give ten injections and repeat after an interval of three months.

The reaction is alarming. The site often appears to be on the point of suppuration, but only once have I seen this follow, in a rather dirty out-patient. There is a good deal of pain locally, and increase of pain in the joints. There *is also fever and sometimes vomiting. The patient must* be warned and should be kept in bed until it has passed. Some patients react little. The days following, before the subsequent injection, are often passed with diminished pain, even in the early days of the course. Most of the patients state that they lose their night pains and find that motility is increased. A sceptical house-physician was convinced that the treatment was a good one, because the patients were so constant in attendance for a remedy which produced such a reaction. Sometimes the sum total of pain is increased until the course is finished, but this is the exception. One course is seldom sufficient.

When the starting and night pains are lessened the methods presently to be described for restoring motility should be begun; before this the tone of the muscles may be improved by massage. The method has yielded a fair number of moderate, and some striking, successes, but the choice of patients is not easy. Colloidal sulphur is too weak to give constant results. At present I am trying a form of sulphur paste much stronger than the oily solution; with it the reaction is less, proportionately to the amount of sulphur injected, but at present it is not certain that the results are better. I have to thank Mr. A. L. Taylor and the dispensing staff of the Bristol Royal Infirmary for much help in the preparation of these compounds.

Physico-Therapeutics.

Ultra-violet radiation, if judiciously applied, stimulates metabolism and immunity processes, and appears to have some sedative action. Its value seems to be greatest in the muscular and neuritic types, but is difficult to assess, for the psychic element is considerable at present.

Diathermy is especially useful for deep joints and active arthritis. The heat produced by the passage of the current causes increased vascularity, analgesia, and the hope of better regeneration; in addition, the heat is sufficient to destroy many micro-organisms. In muscular types of long standing it should be applied cautiously, as there appears to be a risk of increasing fibrosis. Some encouraging results are claimed from pelvic diathermy,[9] which is thought to stimulate prostatic and ovarian secretions. Whether it really has this action or whether the result is due to antiseptic action is uncertain, for, in the cases with marked leucorrhoea, very good results often follow hot permanganate douchings, if applied in the dorsal position and a large amount of fluid used.

Ionization acts in the same way as diathermy, but the action is less powerful; it is of most use for superficial joints. A fair number of my patients ionize themselves after a little training, and obtain a sufficient number of treatments without a very long bill. The ions used have little importance, but sodium thiosulphate or sulphide for

he negative pole, and quinine hydrochloride for the positive pole, give good results. Sulphides are very irritant, and many skins will not stand them. After diathermy or ionization passive and active movements should be practised.

Massage is mainly of value for restoring muscle tone before more active methods can be applied. Passive and active movements at first, later followed by gymnastics, should not be practised until the starting pains of active arthritis have disappeared. Where there is much limitation of movement the joint should be carefully broken down under anaesthesia; it should be remembered that the bones of old-standing cases are fragile. Useful local treatments are the application of irritant liniments, and turpentine with capsicum. Iodine applied as frequently as the skin will stand without vesication is of value chiefly in neuritic types of young adults. A well applied Scotch dressing is often very soothing for superficial joints; it is a remedy much less widely used than it deserves; unfortunately only about 60 per cent. of skins will stand it without vesication.

Treatment of arthritics is best started in the spring or summer; in winter changes of weather cause confusion. If possible, palliative treatment and residence in a more equable climate should be considered until the winter has passed.

The value of spa treatment is difficult to estimate; there appears to be little proof that the metabolism and infections of these patients are modified by any natural mineral water, apart from the flushing, which can be practised at home. The successes of spa treatment may well be due to the more energetic treatment given. As a mental stimulant I advise Vichy water to those patients who have a belief in the efficacy of mineral waters.

CHRONIC FIBROUS EPIPLOITIS.*

BY

R. CHARLES B. MAUNSELL, M.B.DUBLIN, F.R.C.S.I.,

EX-PRESIDENT ROYAL COLLEGE OF SURGEONS IN IRELAND, SURGEON TO MERCER'S HOSPITAL.

I WISH to record briefly a pathological condition which I have never previously seen and about which I cannot find anything in surgical or pathological literature.

An ex-soldier, aged 54, was admitted to Mercer's Hospital on February 18th, 1927, suffering from intestinal obstruction, which was temporarily relieved by enemata. He gave the following history. In 1916, while serving in Gallipoli, he contracted an illness which was characterized by severe colicky pains in the abdomen, diarrhoea, and the passage of blood. He says that he was told that he was suffering from dysentery and that this diagnosis was written on his chart. It is not easy to reconcile this diagnosis with his further statement that he was "operated upon for the cure of haemorrhoids" about a month after the onset of his illness. From that time until February, 1926, his bowels remained free, with occasional attacks of diarrhoea, but he does not think that he passed any blood. From February, 1926, he became constipated and took salts constantly. If he allowed the constipation to persist for a few days he suffered from severe griping pains and could feel "hard lumps" in his abdomen. On six occasions during the past twelve months he developed symptoms of subacute obstruction and was treated, in various hospitals, by enemata as he always avoided operation. He thinks that he has lost weight during the past three months.

The patient is a thin, pale, but hardy looking man. When I saw him he was in pain and it was quite easy to see two prominent swellings in an otherwise flat abdomen. One swelling was in the region of the caecum and the other was almost symmetrically placed on the left side. These swellings were resonant on percussion and almost disappeared, with much gurgling, when massaged. Examination of the rectum gave no help, neither did an *x*-ray examination. The urine was normal and the blood was negative to the Wassermann test.

He was treated by dieting, purgatives, and enemata until March 11th, when I opened the abdomen by a right paramedian incision. When the peritoneal cavity was exposed no intestines were visible; nothing could be seen except a smooth pearl-white membrane with slight prominences where the intestinal swellings had been felt during clinical examination. The membrane was continuous above with the peritoneum covering the stomach, was adherent to the parietal peritoneum on either side outside the colon, and was attached below along the lines of Poupart's ligament and in front of the bladder. At no point was there any adhesion to the anterior abdominal wall, the peritoneum covering which appeared normal in colour and texture. There was no free fluid. The distribution of the membrane was as if a towel had been laid over the intestines and carefully glued at the bottom and sides to the parietal peritoneum.

An opening was made through the membrane, in the mid-line, when it was found to be adherent to the intestines, but separable from them by careful dissection and sponging. It soon became evident that there were three strong fibrous bands incorporated in the membrane: one was adherent deep down in the pelvis and constricted the upper part of the rectum, one compressed the lower part of the descending colon, and the third constricted the ascending colon, just beyond the caecum. When these bands were divided gas could felt gurgling through the intestines. The membrane was now removed in sections as far as the greater curvature of the stomach, over which viscus the peritoneum appeared whiter and felt thicker than normal. The intestines, when freed from the membrane, were found to be universally adherent to one another, but could be separated by sponging just as an adherent prepuce, in a child, can be separated from the glans. Here and there drops of blood oozed from the surface of the intestines and mesenteries, but on the whole the peritoneum appeared intact. No trace of anything like omentum was found.

I cannot give a description of the peritoneum covering the liver and spleen nor a detailed description of the stomach, as the operation lasted so long that I did not feel justified in enlarging the incision for the purpose of exploration. The appendix, which was very much kinked and bound down to the caecum, was removed and the abdomen was closed.

The patient made an uneventful recovery; he is now free from discomfort of any kind and does not need aperients.

Several portions of the membrane were sent to the pathological laboratory in Trinity College, and Dr. John Lait made the following report:

"On microscopical examination these fibrous-looking membranes are found to be composed on the surface of dense hyaline fibrous tissue, while in the deeper layers the tissue is softer and contains many vessels, similar to those found in a late granulation tissue. There is no covering layer of cells on the surface. It is possible that these membranes may be the result of a fibrinous exudate organized into dense fibrous tissue, or else they may represent a chronic inflammatory condition of the omentum, but there is no histological evidence to show that the tissue is omentum."

The portions of membrane were about the thickness of a sheet of Morocco leather.

I have not seen a description of anything similar to the above condition, so I have provisionally named it "chronic fibrous epiploitis." My reasons for thinking that the tissue was originally omentum are the position in which it was found and the fact that no other structure was discovered to represent the omentum.

The conditions most closely allied to this are the thickening of the capsule of the liver or spleen which is sometimes found at a *post-mortem* examination, and the thickening of serous membranes which occurs in those rare cases called polyserositis.

There is no evidence that the condition was tuberculous in origin, and the Wassermann test negatives syphilis. It is hardly conceivable that the condition arose from an acute or subacute inflammation, due to dysenteric or other forms of ulceration, as there were no adhesions to the anterior abdominal wall and there was no fluid present which might prevent such adhesions.

The only conclusion which can be come to is that the process was very gradual and may possibly have arisen in a similar manner to the gauze-like membrane, known as Jackson's membrane, which is so commonly found over the ascending colon.

* Communicated to the Section of Surgery of the Royal Academy of Medicine in Ireland on May 13th, 1927. A report of the meeting will be found at page 1059.

THE DIFFERENTIAL DIAGNOSIS OF JAUNDICE.*

BY

BRUCE MACLEAN, M.D., M.R.C.P.LOND.,

NEWCASTLE, STAFFORDSHIRE.

I PREFACE my remarks with a reference to the theory of Aschoff and McNee concerning bile formation.

Bilirubin is formed from the haemoglobin of the blood stream by the reticulo-endothelial system; it is then passed on by the polygonal cells of the liver to the bile capillaries. That its passage through the polygonal cells alters its chemical characteristics forms the fundamental basis of the van den Bergh test, the interpretation of which may be expressed thus: Jaundice arising from obstruction of the bile duct gives a direct or immediate reaction. Jaundice produced by over-production of bilirubin, in excess of that which can be dealt with by the polygonal cells, gives a delayed or indirect reaction; while a biphasic reaction is produced when obstruction in the ducts is associated with dysfunction of the polygonal cells.

The following classification of jaundice has been suggested by McNee:

1. Obstructive hepatic, producing a direct diazo reaction.
2. Haemolytic, giving the indirect reaction. This is seen in pernicious anaemia, acholuric jaundice, and Banti's disease.
3. Toxic and infective, giving rise to the biphasic response.

Age of the Patient.—I need not dwell on the well known causes of jaundice in infancy, but I would draw attention to two clinical features in childhood: (1) Multilobular or periportal cirrhosis, often attributed to the administration of spirits by ignorant mothers, has its origin in the spleen, slowly spreading to the liver along the portal vein as a pylephlebitis. The picture is that of Banti's disease and has probably no connexion with alcohol. (2) Enlargement of the spleen with jaundice in children under 4 months is almost always, in the absence of acute infections, due to congenital syphilis. An obscure case during childhood always calls for the Wassermann test. In children and young adults the commonest form of jaundice is "catarrhal." Hanot's biliary cirrhosis, a rare disease associated with great enlargement of both liver and spleen, pyrexia, leucocytosis, and eventually marked jaundice, occurs in young adults and children. After 40 years of age cancer must always be suspected.

Sex.—Jaundice in women is frequently caused by gall stones; its development during pregnancy will arouse a suspicion of acute yellow atrophy. It has repeatedly been stated that visceroptosis, so common in women, produces jaundice by kinking of the common bile duct when the duodenum, liver, or kidney is displaced downwards, but it is equally probable that a cholangitis arises from the accompanying intestinal stasis. Alcoholic cirrhosis is common in men, as also is syphilis. Here let me refer to those cases of toxic jaundice following intensive anti-syphilitic treatment by arsenical compounds, and to recent advances in pathology dealing with the detection, by the van den Bergh reaction, of latent jaundice following injections of novarsenobillon, with a view to determining the advisability of further doses and the prevention of arsenical poisoning.

Occupation and Residence Abroad.—Workers coming into contact with tetrachlorethane, phosphorus, etc., are liable to poisoning, and it cannot be denied that hepatic cirrhosis is fairly common among those in the liquor trade. The possibility of the development of hydatid disease in the liver, acute malaria, tropical abscess from amoebic dysentery, and cirrhosis, both from malaria and *Bilharzia japonicum*, must be borne in mind when dealing with patients from abroad.

Family History.—This is of particular importance in excluding familial or hereditary icterus, one variety being found in the newly born, fatal in character, affecting successive infants whose parents are in good health except that the mother during pregnancy suffers not infrequently from jaundice. Another variety is termed "acholuric," inasmuch as bile cannot be detected in the urine; the jaundice is haemolytic. This is the only disease in which the red cells are constantly found to be abnormally fragile, commencing to haemolyse at 0.6 per cent. saline. An almost identical condition is observed in the sporadic variety developing later in life, frequently pyrexial, and apt to be confused with pernicious anaemia, owing to the similar blood picture, but the leucocytosis present is in direct contrast to pernicious anaemia.

The Course of the Disease.

A sudden onset is commonly due to gall stones and catarrhal jaundice, but it may be equally sudden in severe intoxications and infections.

When jaundice is progressive, cancer of the head of the pancreas, of the liver, gall bladder, or bile ducts, should be suspected, and in all doubtful cases I need hardly insist on the importance of carrying out a rectal examination to negative the presence of primary rectal carcinoma giving rise to no symptoms locally. Sometimes chronic pancreatitis with associated inflammation of the bile ducts, very rarely a pancreatic calculus impacted at the junction of the pancreatic and bile ducts, or occasionally a biliary cirrhosis may be the cause of chronic jaundice.

Recurrent attacks are commonly the result of gall stones, especially the "ball-valve" variety; rarely they may be due to chronic pancreatitis or visceroptosis.

The Symptoms.

Important features are:

1. *Pain*—its constancy suggesting growth, its recurrent nature pointing to cholelithiasis; it is absent in catarrhal jaundice and the various cirrhoses.

2. The conspicuous *absence* of the usual concomitant symptoms in acholuric jaundice—for example, normal stools, absence of bile in the urine apart from complications.

3. The occurrence of *rigors* may prove of help, suggesting one of three diseases: (*a*) an infective cholangitis; (*b*) an infective suppurative pylephlebitis, often associated with abscess formation in connexion with the appendix; (*c*) hepatic abscess. A rigor does not exclude an ordinary attack of gall stone, or acute infections such as pneumonia and Weil's disease.

4. *Haematemesis* points to cirrhosis of the liver, particularly alcoholic and splenomegalic (Banti's disease); and here a word concerning haemorrhage associated with jaundice might be useful. Owing to increased fragility of the capillaries, haemorrhages are likely to occur in any jaundiced patient, a point of interest to surgeons; bruising may also result and have an important bearing in medico-legal cases, being mistaken for evidence of violence.

5. A distinguishing feature between obstructive and non-obstructive forms is that in obstruction to the larger bile ducts the *stools* become clay or greenish-white in colour.

6. The patient may give a clue to the initial diagnosis by referring to the high colour of his *urine*; in all cases of jaundice the urine should be examined for bile pigment, as it is found here before it is observed in the conjunctiva, and hence some time before the skin is affected.

It is interesting to recall that during the war it was a practice among French and Italian soldiers to swallow small quantities of picric acid every week or fortnight in an endeavour to produce a yellow colour of the skin and sclerotics, in the hope that it might be mistaken for jaundice and thus procure a transfer to the sick list. The skin in such cases is of a more coppery hue, picric acid is present in the urine, and the van den Bergh test is negative.

It is on record that concussion has given rise to jaundice by setting up a sudden spasm of the bile ducts; and I have known shock to produce a jaundiced condition, attributed to the gastric and duodenal catarrh which frequently accompanies severe mental emotion.

* Read at a meeting of the Staffordshire Branch of the British Medical Association, November, 1926.

The Physical Signs.

The Condition of the Liver.—A neoplasm is usually associated with a much enlarged and irregular shaped liver, but jaundice may be late in its onset and even not apparent throughout the illness. Syphilis may produce an irregular enlargement which is not so great as that caused by the presence of a growth, and jaundice is not infrequently absent. It has been commonly stated that the liver is diminished in size in alcoholic cirrhosis, and though this is true in a certain proportion of late cases, the majority exhibit a distinct enlargement, and it is then either fairly soft, owing to chronic congestion together with an early cirrhosis without splenic enlargement, or it is hard and even hobnailed and associated with a firm big spleen. A sudden increase in the consumption of alcohol will cause also a sudden increase in size of an already shrunken fibrosed liver which will diminish again under treatment. It may be a most difficult matter to diagnose between an ordinary cirrhosis and a "cirrhosis carcinomatosis," the latter being a diffuse carcinoma spreading throughout a cirrhotic liver. An interesting fact is that 25 per cent. of cases of primary carcinoma of the liver occur in alcoholic cirrhosis, but that such livers are rarely the seat of secondary growths. *Diminution* in the size of the liver is a feature of acute and subacute yellow atrophy, but here the jaundice is marked, whereas it is a late clinical sign of portal cirrhosis.

Ascites is in favour of a diagnosis of new growth. When met with in alcoholic cirrhosis it is regarded as a sign of advanced disease or the result of concomitant peritonitis. Both ascites and jaundice are induced when the portal vein and the common bile duct become compressed at the hilus of the liver from local enlargement of the lymphatic glands. A similar occlusion, though rare, has been found in a significant number of *post-mortem* examinations; it was due to aneurysm of the hepatic artery, resulting from a septic embolus in cases of ulcerative endocarditis. A combination of ascites and slight jaundice is observed in cases of heart failure with hepatic congestion, the cyanosis and icterus producing together an almost typical dusky-green colour.

The Gall Bladder and Pancreas.—When the gall bladder is enlarged it is due to some obstruction of the cystic duct or common bile duct, or to a growth of the gall bladder itself. A cystic duct obstruction does not *per se* lead to jaundice. Courvoisier's famous law is of great value provided that the two fallacies associated therewith are recalled. First, that the gall bladder would not enlarge if previously contracted by the presence of calculi, in spite of a cancerous pancreas; and secondly, that the gall bladder may not suffer fibrosis although stones become impacted in the common duct. The commonest growth producing enlargement of the gall bladder is carcinoma of the head of the pancreas. Radiographic evidence is of value in the detection of gall stones containing calcium salts. In cholecystography we now possess a fresh method in diagnosis; it demonstrates anatomico-pathological changes in the gall bladder, including functional activity, while gall stones that cast no shadows on the radiogram may be shown up as negative shadows on the cholecystogram.

Pathological Examinations.

Of the pathological examinations necessary to confirm a tentative diagnosis the most important is that of the blood. In addition to the van den Bergh test, the Wassermann reaction, and the fragility test of the red cells, there is the blood picture of pernicious anaemia to be remembered, that of Banti's disease with its leucopenia and relative lymphocytosis, and the differential counts in the various infections. Similarly may we diagnose the blood diseases producing jaundice from pressure of enlarged glands.

A high proportion of eosinophile cells indicates a parasitic invasion, especially hydatid, where the diagnosis may be strengthened by carrying out the complement fixation and the precipitin reactions of the patient's blood serum. I have seen one such count in which the eosinophile cells reached the enormous proportion of 70 per cent. of the white cells.

An examination for micro-organisms, or a blood culture, will on occasions be found essential in infections such as malaria, Weil's disease, enteric fever, yellow fever, leptospirosis icterohaemorrhagica, and septicaemic conditions. Weil's disease is now supposed to be due to *Bacillus proteus fluorescens*, and haemorrhagic jaundice to a leptospira which has been found not only in rat's blood, but also in the mud-slime of mines.

Amoebae or their ova in the stools will give sufficient evidence for a diagnosis of amoebic dysentery with tropical abscess. The chief tests for pancreatitis combine an examination of the stools for an excess of unsplit fat, of the urine for diastase and glucose, and the mydriasis test by adrenaline.

I must refer also to the condition of the bile and other duodenal contents after extraction by means of Einhorn's tube. We can learn therefrom the presence or absence of pus cells, of micro-organisms (such as *B. typhosus* in carriers), and pancreatic ferments; and would it be saying too much to hope that small roundworms may be the cause of obstruction of the common bile duct? No case of apparent catarrhal jaundice with a tendency to chronicity should be diagnosed as such until, after search for the ova in the stools, or after employment of the therapeutic test, one can conscientiously exclude infestation by *Ascaris lumbricoides*. An examination of the ascitic fluid reveals its character, whether it be inflammatory, malignant, or transudatory.

Finally I will allude to the tests of hepatic efficiency—numerous and at present somewhat unconvincing, but nevertheless holding a lesser place as an adjuvant in diagnosis.

THE CARDIO-THORACIC INDEX:

*A CLINICAL METHOD OF EXPRESSING THE SIZE OF THE HEART.**

BY

E. F. SKINNER, M.A., M.B., F.R.C.P.,

ASSISTANT PHYSICIAN, SHEFFIELD ROYAL HOSPITAL.

THE size of the heart is always of great importance, not only in the examination of individuals suffering from cardiac disease, but also in healthy people when giving an opinion for insurance companies or in compensation claims, and the position of the cardiac impulse, or, as it is rather loosely called, the "apex beat," is generally taken as an indication of the heart's size.

The cardiac impulse is a most valuable physical sign of the heart's action, and its position gives reliable evidence of any change in the situation of the left ventricle, whether this is due to displacement of the whole heart or to hypertrophy and enlargement of this chamber; but it cannot give direct evidence of any cardiac enlargement as a whole.

Accurate determination of the actual size of the heart in any individual is a somewhat lengthy and laborious process, and necessitates very careful percussion combined with x-ray photography; it can hardly be looked upon as a clinical method, but sufficiently accurate information can be obtained by the method to be described.

The accepted definition of the cardiac impulse is the maximum thrust of the left ventricle against the anterior chest wall; this is usually stated to be three and a half to four inches from the mid-sternal line, or, alternatively, half an inch to three-quarters inside the nipple line.

It is quite obvious that the first of these statements can only refer to a certain group of individuals, since the cardiac impulse in a baby of 12 months will bear quite a different relation to the mid-sternal line from that of a child of 12 years, which, again, will be different from that of a man of 50.

The second statement, which uses the nipple line as a standard, is even more fallacious, since the nipple varies so much in position at different ages under different conditions that it is really only of use in dealing with adult men.

* Read to the Sheffield Medico-Chirurgical Society, March, 1926.

Some simple way of recording the size of the heart would be advantageous, and I have attempted to find such a method. Some years ago it occurred to me that it might be possible to express the size of the heart as a fraction which would be a constant factor for all ages if the distance of the cardiac impulse from mid-sternum were put as the numerator of a fraction the denominator of which was the circumference of the chest at the level of the impulse. I made a number of measurements, but it was soon obvious that this factor was only a statement of the distance of the cardiac impulse from the middle line. It then appeared possible that an estimation of the deep cardiac dullness expressed as a linear distance from the extreme limit of the right border of the heart to the cardiac impulse, and used as the numerator of the fraction, with the circumference of the chest used as the denominator, might give a constant for all ages. But before any conclusions could be reached, it was essential to be sure that the right border of the heart could be determined with sufficient accuracy by clinical percussion to be used in such a measurement. The necessity for this step is evidenced by the frequently expressed opinion that percussion of the right cardiac border is largely a matter of imagination. If due care is observed it is possible to define the right border of the heart with a considerable degree of accuracy, as may be seen in the accompanying drawings (Fig. 1).

The method adopted was to percuss out the borders of the heart with closed eyes and to mark the surface of the chest

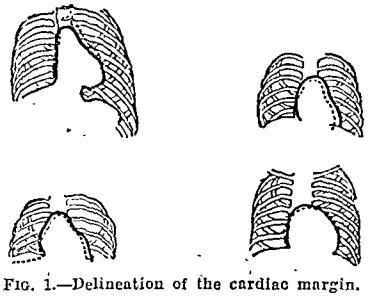

FIG. 1.—Delineation of the cardiac margin.

with a skin pencil; when the percussion was completed, a thin lead wire was run round the pencil marks and kept in position by strips of strapping. An *x*-ray photograph was then taken with the tube carefully focused and centred at a sufficient distance to give parallel rays; the shadow produced by the heart can then be compared with the much denser shadow of the lead wire. I think it will be seen from Fig. 1 that it is possible to delineate the heart's borders with a fair degree of accuracy. Having decided that clinical percussion if carefully and honestly carried out could be relied upon, a number of measurements have been recorded. It appears fairly clear that by expressing the linear cardiac dullness as the numerator and the circumference of the chest as the denominator a fraction is obtained which at any age or sex is almost a constant; it approximates to 1/6, and for the sake of reference I have called this the "cardio-thoracic index." A more accurate numerator would be the distance of the right border of the heart to the impulse, measured by callipers rather than a tape, but the latter is generally available, and the error is a very slight one.

The actual indices obtained by the above method are seen in the accompanying tables, the first of which represents measurements of what may be considered normal conditions. In both tables only the denominator of the fraction is given, for the sake of simplicity. Here it will be noted that there is only one group in which the fraction is in any way strikingly below 1/6, and this in women between 20 and 40 years of age. It is due to the development of the breasts in this period of life; but even including these low fractions the average for any age of either sex is 1/6.3.

Table II shows a few measurements of abnormal conditions, and I need not detail them, as they are depicted here with the accompanying pathological condition.

cardio-thoracic index shown beside each tracing, together with the age and sex.

Fig. 2 may be considered to represent normal chests, and it will be seen that with such different sizes and shapes

at various ages the actual fraction is remarkably constant. Fig. 3 is that of similar cyrtometer tracings of individuals with abnormal conditions; whilst Fig. 4 shows drawings of what may be called "freak" chests. I merely include these last by way of interest, and as examples of the one or two conditions in which it is clinically impossible to determine the factor I have called the cardio-thoracic index which is emphasized in Fig. 5, which is an illustration of a chest with extreme emphysema. In such cases, or with chests which are very abnormally shaped, the most careful percussion of which I am capable has failed to map out the deep cardiac dullness. But such cases are comparatively rare, and in them every other clinical method is equally fallacious, so they do not materially invalidate the suggestion I have made above—namely, that the size of the heart can be expressed as a constant for any age, the deep cardiac dullness being one-sixth of the circumference of the chest at the level of the cardiac impulse.

ARTIFICIAL PNEUMOTHORAX IN ADVANCED PULMONARY TUBERCULOSIS.

BY

DENNISON PICKERING, M.D.CANTAB.,

SENIOR PHYSICIAN, PENDYFFRYN HALL SANATORIUM, PENMAENMAWR.

IN the BRITISH MEDICAL JOURNAL for February 19th, 1927 (p. 323), a case of pulmonary tuberculosis is described by Dr. Bernard Hudson in which, in spite of a history of old-standing disease with a recent severe "flare-up," an artificial pneumothorax was induced and resulted in considerable and continued improvement. The two following cases are of interest in this connexion.

CASE I.

An ex-officer, aged 26, was admitted to this sanatorium on August 30th, 1922, with a history of persistent cough and cold since the previous winter. Both upper lobes and the upper parts of both lower lobes were involved. The patient improved at first, increasing 28 lb. in weight. For the next year he held his own, but then lost ground slowly.

On August 27th, 1925, intermittent haemoptyses began, and on August 29th an artificial pneumothorax was induced. Intermittent bleeding continued for twelve hours, after which there was another haemorrhage of 10 ounces. A refill was given, and the bleeding gradually stopped.

The records of the first operations are as follows:

August, 29th, 1925, 1 a.m.	...	−4, −2	...	
,, ,, 2.15 p.m.	...		...	
September 1st, 1925	...	−3, +1	...	1,000 c.cm. ... −2, +3
,, 5th, ,,	...	−2, +4	...	1,000 c.cm. ... 0, +5
	...	−2, +5	...	500 c.cm. ... +1, +7
				400 c.cm. ... +2, +6

The patient gradually recovered from the effects of the haemorrhage and improved in general condition. Fairly high pressures were kept up throughout, and at the beginning of August, 1926, when I took charge of the sanatorium, the last records had been:

July 13th, 1926	...	−8, +2	...	800 c.cm. ... −3, +5
July 27th, 1926	...	−10, +2	...	800 c.cm. ... +2, +7

X-ray records had not been kept.

When I first saw him the patient had been in bed for four days because his temperature had risen to 102° for a couple of days after the last refill (June 27th), and he had had vague pains in the left side of the chest. On August 13th I attempted a refill, but found the pressure −1, +2. After introducing the needle in a different place the pressure was again +2, +3, so the attempt was abandoned. After this the temperature rose to 99.4°, and there were again vague pains in the left side of the chest. About ten days later fluid appeared at the left base, and increased slowly until November 22nd, when it had reached the level of the third intercostal space. This was confirmed by *x*-ray examination. Fluid replacement was considered, but in the absence of marked dyspnoea or other signs of cardiac embarrassment, and in view of the pleurisy in August, it was decided to wait. The fluid gradually decreased and finally disappeared, leaving signs of much-thickened pleura. The weight, which for a long time had remained about 10 st., is now over 10 st. 5 lb., temperature and pulse are normal, and the patient is walking from three to four miles a day. The sputum is slight, and tubercle bacilli have been found only once since December 30th, 1926. The adventitious signs in the chest have remained about the same, except in so far as they have been modified by the presence of fluid and air respectively.

It is clear that in this case the ultimate prognosis is poor and the immediate risks not inconsiderable. At the same time the pneumothorax, which but for the haemorrhage would never have been attempted, has undoubtedly improved both the chances and the comfort of life. The fluid, by keeping up partial collapse for some months after the refills were stopped, doubtless contributed towards the result.

CASE II.

A girl, aged 20, was admitted in March, 1925, with a history of slight haemoptysis three and a half years previously and a recurrence in 1923. On admission, the right upper lobe and the upper half of the lower lobe were involved, and there was some suspicion about the left mid-scapular region. After an *x*-ray examination, Dr. A. E. Barclay of Manchester reported: "... evidence of extensive disease on the right side, which is almost all definitely of old standing. The apex is largely consolidated and fibroid, the trachea being dragged across fully three-quarters of an inch to this side. ... From the interlobar septum downwards there are extensive changes of fibroid type. ... On the left side ... some increase in root shadows with nodules, which are sharply defined, and do not give the impression of active disease."

In October an unsuccessful attempt to induce an artificial pneumothorax was made. The patient's condition meanwhile remained very much the same.

When I first saw her, in August, 1926, the symptoms were: troublesome cough frequently leading to vomiting, copious sputum swarming with tubercle bacilli, dyspnoea on exertion, and lack of energy. There were signs of definite activity at the left apex, as well as on the right side. The *x*-ray appearances were much the same as in February, 1925.

The patient asked me if nothing further could be done. The case did not appear to be particularly suitable for the use of sanocrysin, and so, before considering such a line of treatment, or further surgical measures, I felt that another attempt to induce an artificial pneumothorax should be made. The initial operation was performed on September 2nd, 1926, and I was fortunate enough to get into the pleural cavity without difficulty. The earliest records are as follows:

September 2nd, 1926	...	−3, −2		
,, 3rd, ,,	...	−4, −2	...	250 c.cm. ... −2, −1
,, 4th, ,,	...	−3, −1	...	350 c.cm. ... −2, 0
,, 8th, ,,	...	−2, −1	...	400 c.cm. ... −3, 0
			...	400 c.cm. ... 0, +1

At first only partial collapse was obtained. Almost the whole of the apex was adherent, and there were a number of adhesions near the base. Soon, however, the latter adhesions began to give way gradually, and at the beginning of January collapse was almost complete; the inner parts of the apex and upper lobe, however, remained adherent.

At the beginning of October no râles could be heard on the left side. *X* rays showed the trachea in normal position. On November 17th no tubercle bacilli were found, and none have been found since; soon after that date the cough disappeared and the sputum ceased.

There is still some dyspnoea, and a very quiet régime is being followed, with one short walk daily. It has not been possible to increase the intervals between refills beyond a fortnight, or even less, as re-expansion usually takes place rather rapidly.

In this case, owing to the length of history and the probability of adhesions, the chances of inducing an artificial pneumothorax appeared small. The operation was undertaken rather as a forlorn hope before going on to more serious surgical measures. Yet not only did the operation succeed, but, although the ultimate outlook is doubtful, the chances of life are certainly improved, and in the meantime the absence of severe cough with copious, offensive sputum, and the knowledge that she is no longer a source of danger to others, are in themselves a great boon to the patient.

Memoranda:

MEDICAL, SURGICAL, OBSTETRICAL.

THE LEUCOBLASTOSIS OF GLANDULAR FEVER.

A HEALTHY boy, aged 4 years, had been ill for one day. There was marked enlargement of cervical glands on both sides; the tonsils were red and swollen, and the temperature was 103° F. In three days he was much better, the tonsils were still large, and the swellings at the angles of the jaw were even greater. He made a good recovery.

On the fourth day, when glandular swelling was most marked, blood films showed normal red corpuscles and considerable leucocytosis, with differential count: polymorphs 50 per cent., eosinophils 2 per cent., mast cells 1 per cent., lymphocytes 29 per cent., mononuclears 13 per cent., plasma cells 1 per cent., myelocytes 1 per cent., leucoblasts 3 per cent. Leucoblasts in films from angina were new to me at the time (September, 1920), and, with the remarkable glandular enlargement, suggested incipient leukaemia. In referring to glandular fever Professor Gulland[1] said that he had never seen myeloblasts (leucoblasts) in the blood of these cases. As textbooks are reticent about these cells, it may be useful to describe them briefly.

The leucoblast resembles a large mononuclear cell. Its basophil cytoplasm is ample and may show azure granules. Its large oval or reniform nucleus stains well in a striped pattern. But cells differ in age, and, therefore, vary in form and staining. The form commonly seen is (1) a big cell with large kidney-shaped nucleus and ample light blue cytoplasm with or without scanty azure points. Development now proceeds in one of two directions: (2) the nucleus stains with denser stripes, and the cytoplasm shows numerous coarse, dark violet granules; or, (3) the nucleus becomes irregular, even polymorph, and the cytoplasm paler or lilac; these cells are soon indistinguishable from large mononuclears.

Some of the first are easily identified, and the second form is quite characteristic and not to be mistaken for any other cell of the blood. For this reason I included only the second form in my differential count and underestimated the leucoblasts present.

The description is in terms of Romanowsky staining, and for identifying leucoblasts I prefer the polychrome Manson blue method,[2] because it brings out the coarse, violet granules better and in a greater proportion of cells, just as in benign tertian infections it deeply stains Schüffner's dots. Jenner-Giemsa fails to do this.

West Ealing. ROBERT CRAIK, M.D.

PULMONARY EMBOLISM FOLLOWING FRACTURE OF LEG.

THE following case is of interest in connexion with the modern treatment of fractures by early massage, and raises the question whether it is likely to cause separation of blood clot and the resulting tragedy of pulmonary embolism. The case occurred at the height of the recent influenza epidemic, and splints were taken down only three or four times when the joint was very gently massaged by myself. Had my attentions been more frequent or vigorous I should probably have charged myself with being the unwitting instrument of causing this unfortunate man's death. It would be of interest to know how often pulmonary embolism follows fractures, whether treated by massage or otherwise.

A stone-breaker, aged 62, of spare build and in good health, fell when getting over a stile and sustained a simple Pott's fracture of the right ankle, the fibula being fractured about an inch and a half above the external malleolus and the medial malleolus torn off. Under chloroform the fracture was set and kept in position by lateral splints; the leg was hung in a Salter's cradle. Union was perfect, and movement quite good. Three weeks after the injury the patient complained of pain in the left side for which I was unable to account; I could detect no abnormal sounds, and put it down to a slight pleurisy due to his sleeping three feet away from an open window. I ordered mustard plasters, which were used for four or five days; the pain did not subside, though the patient was in excellent health and in the very best of spirits, expecting to be allowed up on crutches in a few days.

On the twenty-fourth day of the injury the patient was laughing and joking with his neighbours; on the twenty-fifth day his daughter was wakened at 6 a.m. by her father's peculiar breathing; she got up and went for a neighbour. The patient was dead before her return in a few minutes. A *post-mortem* examination was not performed.

As there was no heart lesion or other organic disease I think there is no doubt that this was a case of pulmonary embolism.

Reports of Societies.

CLEFT PALATE.

A DISCUSSION took place in the Section of Surgery of the Royal Society of Medicine on June 1st on the operative treatment of cleft palate. In the afternoon a number of cases in which operation had taken place some years previously with good anatomical and phonetic results were exhibited, and a discussion began at five o'clock which, with a brief interval for dinner, continued until after ten. Mr. V. WARREN LOW presided.

Sir JAMES BERRY exhibited several patients upon whom he had performed his lateral approximation operation, and the speech results were demonstrated to the meeting. The test sentence which they were asked to repeat was: "On a bridge, by a church, I met a flock of turkeys"; but one of the patients, a young man, said that he was not going to utter such nonsense, and he made a perfect little speech, in which he paid a tribute to his old nurse, who had taken pains after the operation in his childhood to educate him in voice formation. Sir James Berry said that the main, almost the only, object of operating upon a cleft palate was to enable the person to speak intelligibly. The view formerly held by some that the operation might be regarded as a life-saving one was now, he thought, exploded. A small proportion of clefts which were very narrow and limited to the soft palate could doubtless be closed within the first weeks or months of infancy by the operation of lateral approximation; but in the vast majority of cases it was impossible at this very early stage to perform the operation with any reasonable chance of success owing to the width of the cleft and the lowness of the palatine arch. The age of operation should be the earliest at which, in the experience of the operator, a lateral approximation operation would give a reasonable chance of closing the cleft. Generally this was from 18 months to 4 years. In the really difficult cases, such as a wide cleft involving the soft and most of the hard palate, it was often a good plan to close the cleft of the soft palate first and to leave the hard palate unclosed for a time, rather than risk failure of the whole line of union by attempting too much. It was the soft palate that was most important to close. If the hard palate was closed and the soft left unclosed after an operation little good usually was done; on the other hand, if the soft palate were successfully closed and the hard palate left unclosed the patient might be greatly benefited. His own views as to operation were based upon 276 cleft-palate patients, upon whom he had operated during the last thirty-three years. Before operation gross defects of teeth and tonsils should be remedied, though he thought routine excision of tonsils or adenoids unnecessary. In the case of wide and difficult clefts lateral incisions to relieve tension were frequently necessary on one or both sides, but they should, in his opinion, be as short as possible, seldom more than 1/2 inch in length, except in the case of secondary operations for large holes in the hard palate. Of late years he had been using lateral incisions less and less, replacing them as regards the soft palate by the use of deep tension stitches and rubber plates after the

method recommended by Brophy of Chicago. He was afraid to use the very long lateral incisions recommended by some, lest they damaged too much the palatine and pharyngeal muscles.

Mr. GREY TURNER said that the total number of cases of cleft palate with which he had dealt operatively was 155, and upon these he had done 195 operations. The average age, excluding the cases over 12, at time of operation was just over four years. The deaths numbered four: haemorrhage, scarlet fever (2), under anaesthetic. Excluding these and the very recent operations, the anatomical results in the remaining 134 showed a complete restoration of the palate in 66; a union of the palate, but one or more pin-head holes persisting or a slightly bifid uvula, in 21; an enclosed area just beyond the alveolus, the remainder of the palate being completely closed, in 11; a shortened palate with no uvula and the soft palate in the form of a V in 8; a great part of the hard palate not united, but very little separation, in 9, and increasing degrees of non-success in the remainder. The functional results in 80 cases traced, all of them more than one year after operation, the average being six years, were: normal speech, 10; good, 31; moderate, 25; poor, 17; unintelligible, 3. Out of the 66 cases of complete anatomical restoration, 44 had been traced to discover the ultimate speech result, which was normal in 7, good in 20, fair in 14, and bad in 3. Sometimes with a bad anatomical palate the patient spoke wonderfully well, and conversely. He had thought that bad speech results might be due to the fact that the patient had had no opportunity of learning to speak well until he had already learned to speak badly, and that if the Langenbeck operation could be done before he learned to speak at all, better results might be forthcoming. In this hope he had been disappointed. Many of the patients operated on at a very early age and with complete anatomical success had not been good speakers. Why did these results vary so much? He thought it had something to do with the general architecture of the naso-pharynx, and with the whole of the muscular and neuro-muscular apparatus, and not only the palate. As to the age at which operation should be done, so far as soft palates were concerned, during the first year of life the cases did exceedingly well. With regard to other patients he had rather extended the age of operation. What mattered more than the age was the general health of the patient. If the operation took place in two stages, the soft palate should be operated upon first, and one should be content not to make such a good job of the hard palate. The making of a lateral incision was no essential part of the operation. If it was found that the approximation of the edges of the cleft could not be done without tension, then was the time to make a lateral incision. For main suture material he preferred silkworm gut, but for other than the main suture he was using catgut more extensively than he used to do.

Mr. O. L. ADDISON said that the two openers of the discussion had mentioned only the operation of medium suture. Of the other operations he had had no experience except the flap operation, and after seeing the immediate and late results of that operation he had no hesitation in saying that he thought it a hopeless procedure. The immediate results as regards mortality were grave, as regards closure of the palate they were bad, and the remote effects were perfectly deplorable. He had recently seen three children, aged about 14 or 15, who had come to him for other conditions; a flap operation had been done upon them some time previously, and in each case it would have been infinitely better had they been left alone. Speech in his opinion was entirely a question of determination and training. Good anatomical results were sometimes followed by unintelligible speech. During recent years he had confined himself to the Langenbeck operation, the only modification being that he used a long lateral incision. It was not until he began to use that incision that he got any successful results at all. He practically always removed the tonsils before the palate operation, mainly because he regarded them as reservoirs of potential sepsis. He had come to the conclusion that one got better movement by employing a long lateral incision because one had to do less separation of the soft palate from the back of the hard.

Dr. VICTOR VEAU (Paris) said that he had first operated according to the Langenbeck method, but he found it not very satisfactory in anatomical results, and very unsatisfactory in speech results. Therefore he turned to the method of Arbuthnot Lane, which he had practised in about 320 cases, and anatomically he had had 91 per cent. of successes and 9 per cent. of what he called checks. The phonetic results were better also than with the Langenbeck operation. In his view the excellence of the phonetic result was not altogether dependent on the anatomical result, but had to do with the child's intelligence and above all with acuteness of hearing. He described by means of a series of illustrations his exact technique, especially his provision for a complete epithelial covering for all raw surfaces, and his practice of muscle suture as a means of preventing tension on the palate.

Mr. A. T. PITTS, speaking as a dental surgeon, said that many dentists had been hostile critics of the operative treatment of cleft palate, but while there might be on their part an unconscious bias in favour of prosthetic treatment, it must be acknowledged that surgery did not always succeed. Even if closure of the cleft were obtained the functional results might be poor. A most serious degree of deformity of the jaws might follow. When surgical efforts failed the original condition was much worsened, and the case drifted into the hands of the dentist as a last resort. Nevertheless he believed the best treatment of cleft palate to be surgical, though as at present practised it was not ideal in its result. Both the Langenbeck and the flap operation tended to produce some distortion of the dental arch, the flap operation bringing about a unilateral narrowing, and Langenbeck's a bilateral narrowing. The deformity produced by the Langenbeck operation was far less than that which followed the other. If it could be shown that the percentage of success in closing the cleft was greater with the flap, or that the functional results were better, then the greater degree of deformity of the dental arch might not outweigh these advantages: but if the operative success and the functional success of the two operations were the same the effect on the dental arch might well be the determining factor. His impression as a dentist was that so far as the closure of the cleft and the speech results were concerned, the flap operation had no such advantage over the Langenbeck as to outweigh the bad effect on the teeth and jaws. He doubted also whether repeated attempts at operation were wise. Perhaps the surgeon would do well to abrogate early in favour of dental treatment before the tissues were so damaged or distorted that prosthetic restoration became difficult or could only be partially successful. He urged the need for a greater liaison between surgeon and dentist.

Mr. CYRIL NITCH said that he had records of 86 cases operated upon, of which only 43 had been traced. The age at which the cleft should be closed depended upon the type of operation performed. If the flap operation of the Lane type, it must be performed about four months before the teeth were developed. He had not performed this operation since 1913, for although one could always guarantee the closing of the cleft by that method, the soft palate was always short and rigid, and speech, therefore, was bad. The age he generally selected was 18 months to 2 years. When the cleft was very wide the operation was deferred until the palatal processes and the soft palate had grown wide enough to afford tissue offering a reasonable chance of success. He always tried to close the whole cleft at one operation, provided the anterior palatine arch could be preserved. When the alveolus was cleft the mother was taught, after the hare-lip was sutured, to press on the alveolus twice daily with the thumb and so drive it backwards. He always made long lateral incisions, and placed them close to the alveolus, at the posterior border, curving them outwards and directing them downwards towards the last molar tooth of the lower jaw. One important point after operation was to teach the mother to massage the soft palate as soon as firm union had taken place, by putting the ball of the finger against the soft palate and rubbing transversely. With his modified Langenbeck method with long relieving incisions and lateral splints, the failures had been reduced to 17 per cent. instead of the 50 per cent. which had followed the unmodified Langenbeck procedure.

Mr. CORTLANDT MACMAHON, who has been in charge of the Speech Clinic at St. Bartholomew's for sixteen years, said that in the speech of these patients there were five blemishes—the pronunciation of *k*, *g*, *d*, and *t*, and, most seriously of all, *s*. The education for getting these letters was really very easy, and even in the case of *s* it could be done by driving the tongue down and getting a stretching between the soft palate and the back of the tongue. Some of the good speakers would be better still if they were trained to lower their voice by an octave. His earlier experience of speech training in these cases was with the flap operation. Lane's operation gave good speech if the patient was properly trained, but if the training was deficient the result was likely to be less good than after Langenbeck's operation with similar training.

Mr. H. D. GILLIES added a few points about secondary operations. The great majority of the cases would be vastly improved by severing the soft from the hard palate, making provision for an epithelial covering of all raw surfaces, and interposing an appliance between the soft and the hard palate, so placing the soft palate with its muscle that it could assist in closing off the nasal from the buccal cavity. Mr. Gillies also remarked upon the contrary opinions which had been expressed by various speakers as to the speech result. Mr. Addison had said that the power of speech was due to the intelligence of the patient, Dr. Veau that it was due to acute hearing, and Mr. MacMahon that it was due to cunning movements of the throat by means of which the oral-nasal failure was circumvented. This only showed the complexity of the problem.

Mr. C. H. FAGGE said that up to the end of 1924 he had operated on 114 cleft palates. He had aimed at as complete anatomical re-position of the tissues as possible—in other words, closure of the hard palate and closure of the soft. He agreed that the soft palate was the more important part, but he had not neglected to try to close the hard. On his 114 cases he had performed 218 operations, but that figure was fallacious, because some of the operations were on the lips, and some followed defects of a previous lip operation, necessitating an epithelial inlay. A good many also were operations for the closure of holes in the palate, done before he learned that the holes might well be left alone because they closed of themselves or got smaller. He described a combined operation which he used in the largest group of cases—those, namely, with a unilateral cleft, nearly always running right through into the nose. First of all he did a Lane's flap on the hard palate, then the hare-lip operation, and then followed with the classical procedure for closing the soft palate. He had never failed to close the hard palate with a Lane's flap, nor had he seen any case break down. The Lane's flap operation on the hard palate did not make the second operation on the soft palate more difficult. He liked, if possible, to undertake both operations, for the closing of the hard and of the soft palate, before the child's first dentition, for then he was more assured of a good anatomical result. He had operated on a fair number of adults, but the case in which he felt the greatest difficulty was with the child of 2 or 3. The operation in the case of a small baby was not difficult, and the testimony of the sisters was that the baby was not difficult to nurse. With his combined method of operation he had had 62 per cent. of successes, 22 per cent. of partial successes, and he did not think any operation could be written down as an absolute failure. Sometimes, however, a good anatomical result went with a bad functional result, and again, despite a bad anatomical result, the functional result might be quite good. In the Langenbeck operation he made use of a very long incision on either side to relieve tension.

Mr. KELSEY FRY, speaking as a dental surgeon, said that he had had to do with a large number of children who had undergone operation but without success from the point of view of function. The treatment that the dental surgeon could give in these cases of surgical failure was very difficult and complicated. Special appliances had to be made which always wanted repair and which were a nuisance to the child for the rest of his life. If the surgeon could provide for the cleft palate patient a functional soft palate it would be an easy matter for the dentist to provide a hard palate.

Mr. F. W. GOYDER (Bradford), speaking as a provincial surgeon whose colleagues did not touch these cases, and who therefore had little opportunity of comparing his results with those of others, said that he had dealt with about 150 cases, but he could not give exact statistics as to the results. He began with Lane's operation, but he got disgusted with the results, and during the period of the war and for some time afterwards he took very little interest in this subject. Now he had begun again, and increasing experience had made him more certain of closing the cleft, but at the same time more pessimistic as to the final results with regard to speech. As time had gone on he had operated later and later in life, and now he rarely performed an operation on a child younger than 3 years of age. He performed Langenbeck's operation except when the clefts were very wide. In his last 22 cases he had used a flap in 11, and the median operation in the other 11. Even when doing Langenbeck's operation, however, he used narrow flaps and united them so as to leave no raw surface. He was not in favour of two-stage operations.

Mr. L. E. BARRINGTON-WARD said that his remarks were based on 148 cases (132 hospital and 16 private) on which he had operated since 1914. Of these, 29 were not to be traced. The failures numbered 6. In one of these cases there was a complete horseshoe cleft, which was the hardest type of all to deal with. Three showed a deficiency of the hard or soft palate, and in two the alveolus was still cleft. With regard to age, he believed that if a hare-lip was associated with the deformity, operation should take place as early as possible; his usual rule was to operate at 1 month. Otherwise he preferred to operate at the age of 18 months or 2 years or later. The nature of the operation which he did might be described as Langenbeck's, but he thought that posterity might prefer to call it Berry's operation. It was lateral approximation to the median suture. He made lateral incisions, their extent entirely depending upon the case. For sutures he used the finest ophthalmic silkworm gut. He believed that relaxation sutures nearly always cut out or produced ulceration, and added to the infection. With regard to the speech tests in his cases, 58 had been tested recently, and in 20 the speech was good, in 18 it was fair, and in 20 it was bad. Four of the patients in this last category were mental deficients. If he were asked with regard to the prognosis from the point of view of speech in any case of cleft palate he would have regard not so much to the type of cleft as to the intelligence of the mother.

Mr. TWISTINGTON HIGGINS said that his own cases numbered only 47, and they had all been operated on since 1921. He had followed the method advised by Mr. Gillies, which was relatively easy; the only difficulty was the epithelial graft with which it was necessary to cover the raw area. In 15 cases also he had followed the method advised by Mr. Addison, including even the removal of the tonsils. What had impressed him about the tonsils was that almost universally they were infected, even though externally they might not appear to be so. He thought that the tonsil was fully proved to be a focus of infection in these cases. The 15 cases which he had done according to Mr. Addison's method gave better results than he had achieved by the unmodified Langenbeck operation, and in 14 of them there was perfect anatomical closure.

Mr. WARREN LOW, in closing the discussion, congratulated the Section on the success of the occasion. Seldom had so many successful cases of cleft palate been gathered together in one building. One thing that struck him was the extraordinarily hopeful outlook now for a child who was born with cleft palate, and he thought that the discussion had been a wonderful justification for what was known as the median suture method. He was sorry that not more had been heard about the Brophy operation. Dr. Brophy had sent from Chicago a small contribution to the discussion, chiefly relating, however, to the number of cases which certain of his colleagues had done and the negligible proportion of mortality and necrosis.

Sir JAMES BERRY and Mr. GREY TURNER also replied without, however, taking up any of the points which had been raised in the debate, contenting themselves with an expression of gratification that so noteworthy a discussion had been forthcoming.

CHRONIC FIBROUS EPIPLOITIS.

At a meeting of the Section of Surgery of the Royal Academy of Medicine in Ireland on May 13th, Mr. R. C. B. MAYNSELL, who was in the chair, described an unusual condition which he termed "chronic fibrous epiploitis." The case is reported in full at page 1051 of this issue

Mr. ARTHUR CHANCE said that he had never seen a similar case, but he presumed that the process was an inflammatory one, as it was apparently limited to the abdomen, below the transverse colon. He thought it was a pity that it had not been possible to see the peritoneum covering the liver and spleen.

Deep X-Ray Therapy.

Dr. M. HAYES read a paper on experiences of the treatment by deep x rays of 180 cases, which were chiefly malignant. He said that the qualitative and quantitative standards in the matter of dosage evolved by Saitz and Wintz had laid the foundations of rational radiotherapy. "Deep x-ray" and "Erlangen treatment" were not synonymous terms. Deep or highly penetrating x rays were now universally employed in the treatment of malignant disease, and the results obtained were much better than by the older methods. The Erlangen technique, whereby "the lethal dose" was administered at a single sitting of many hours' duration, did not, in the experience of many, give as good results as carefully estimated fractional doses of highly penetrating x rays administered over long periods. In the prophylactic post-operative treatment of mammary carcinoma repeated fractional doses gave better results than massive doses. Inoperable cases were ameliorated—pain was relieved, ulceration was retarded, and life was prolonged. Rectal carcinoma was likewise benefited, and sometimes inoperable cases became operable, or the symptoms might completely disappear. Recurrent oral carcinoma was not materially benefited, but some primary lesions, more especially of the lip and the tonsil, responded very favourably. Radium combined with x rays in the treatment of inoperable uterine carcinoma arrested discharge and haemorrhage and greatly relieved the symptoms. Some post-operative recurrences had responded favourably to treatment. The result obtained in carcinoma of the prostate was not very favourable, but the symptoms of prostatic hypertrophy usually disappeared within two months. In sarcoma of bone the response to treatment was often very satisfactory.

The CHAIRMAN said that for many years he had been treating cases of mammary carcinoma in which recurrence had taken place by x rays. He had never seen the least harm follow the treatment, and practically always benefit had resulted. After a complete operation for carcinoma he made it a rule always to get the patients treated subsequently by x rays, but it was too soon yet to say what the effect of this would be. He, however, thought that it was one or even more than one course of x-ray treatment. Usually patients had fifteen exposures, followed by a rest, and then a further fifteen exposures. He thought it was essential that a patient should be told if he had cancer, because otherwise he would not allow the surgeon to perform a sufficiently radical operation; a patient should be informed that the only hope of cure was a really radical operation, and also post-operative treatment by x rays. He had had only one case of a malignant thyroid x-rayed. It was, however, a very advanced case, and so was not a fair test. Radiation seemed to him to be a method of great benefit in the post-operative treatment of cancer.

Dr. R. STUMPF said that Dr. Hayes's technique was almost the same as the technique which was being used in Germany, and which he was now using in Dublin. He thought, however, that scattering of the dose for two to six days did not make much difference to the final result. In uterine cancer his experience had been mostly limited to inoperable cases. He had given prophylactic post-operative treatment to twenty cases, and of these, fifteen had remained free of the disease for varying periods. He thought that every inoperable case of mammary cancer should be given a trial of treatment by x rays, and every case operated on should be given post-operative treatment by x rays. In cancer of the lip operation should be undertaken wherever possible, and radiation should be given to inoperable cases. The thyroid was one of the most satisfactory organs to treat by means of x rays, and he thought that in thyroid cases, if initial treatment by x rays was given, the results obtained from operation would be more successful. In cancer of the rectum there was nothing to choose between operative and x-ray treatment, but a combination of the two gave fairly good results—at any rate, better than treatment by either means alone. By the use of x rays one could sometimes render inoperable cases operable. In his experience of cancer of the rectum, women did not respond to treatment so satisfactorily as men.

Mr. W. C. STEVENSON said that if very small doses of radium had been given at very long intervals the results obtained would not have resembled those which Dr. Hayes had obtained, but there would have been less disturbance of the patient, and it was likely that better work would be done without affecting the patient's constitution. He thought that very massive doses of radium had a bad effect on the other tissues besides the malignant tissues, and that the resistance of the tissues was very much lowered by an overdose. The one risk of giving a small dose and not repeating it was that of increasing the power of the cancer to resist radiation subsequently. He liked to see a malignant growth disappear altogether, as he always felt suspicious if there was a lump left behind after irradiation. He had found that cases of cancer of the breast did well by radiation. The results that he had obtained in cases of cancer of the mouth were, on the whole, unsatisfactory. He had treated some cases in which the malignant disease had involved the bones, but without much effect. He thought it was necessary to recognize that some patients could not be helped much by radiation, and also that in some cases the results could not be permanent, although pain might be temporarily relieved.

Dr. HAYES, in replying, thought there was very little doubt that small quantities of radium did stimulate, and that large doses destroyed and inhibited. This had been proved on vegetable matter, but how far it could be employed on human beings it was difficult to know. He also liked to see the lump disappear altogether, but in many cases he thought that complete disappearance of the growth could not be expected. One of the rare occasions on which he had seen the whole growth disappear was in a case of sarcoma of the tonsil. Other growths, he thought, could not disappear without leaving fibrosis, and the problem was, how long the cancer cells remained in the fibrosis. This, in his opinion, was a very strong argument for prophylactic treatment following surgical radiotherapy. In cases of prostatic hypertrophy he generally tried to give a dose of from 90 to 100 per cent. It was as yet too early to say whether the treatment of these patients by radium would render operation unnecessary in the future.

MENINGOCOCCAL MENINGITIS.

At a meeting of the Section of Pathology of the Royal Academy of Medicine in Ireland on April 29th, the President, Professor J. W. BIGGER in the chair, Dr. R. H. MICKS and Dr. J. LAIT showed jointly the brain and spinal cord from a case of meningococcus meningitis in a child. The main clinical features of the case were that, in spite of early and vigorous treatment, the patient grew steadily worse and died in the ninth week of the disease, and that subarachnoid blocking gradually developed. During the first week lumbar punctures withdrew from 40 to 50 c.cm. pus each time with consequent relief of headache. Then less and less fluid was obtained on each occasion and no relief to the headache was afforded by the withdrawal. Finally, about six weeks after the onset, it became impossible to obtain fluid. Although headache and vomiting were present no cranial nerve paralyses or optic neuritis developed during the nine weeks. From the start wasting and spasticity of the lower limbs were unusually well marked. Dr. Lait reported the following pathological findings. The pia-arachnoid was very congested and dry,

and there was some flattening of the convolutions over the surface of the cerebrum, but no exudate was found. The base of the brain, however, showed a thick, greenish-yellow exudate in the regions of the cisterna interpeduncularis and the cisterna magna. The rest of the base of the brain was free from exudate. All the ventricles of the brain were dilated and filled with a turbid fluid. The ventricular walls were hyperaemic, with adherent masses of a fibrino-purulent exudate. There was softening of the brain tissue around the ventricles. The hydrocephalus was due to the blockage by the exudate of the foramina in the pial roof of the fourth ventricle. There were extradural and subdural haemorrhages in the dorsal and lumbar regions of the cord. A purulent exudate in the pia-arachnoid extended practically along the whole dorsal and lumbar regions of the cord, especially on its posterior aspect. Dr. Lait said that infection in these cases was spread by the blood stream rather than directly through the nasopharynx. He mentioned the view of Carnegie Dickson that ventricular infection often preceded that of the meninges. The causative organism, in this case, had been frequently isolated from the cerebro-spinal fluid, but no ventricular puncture had been made.

The PRESIDENT did not consider this a typical case of cerebro-spinal meningitis either clinically or pathologically. He discussed the spread of the meningococci from the nasopharynx to the brain, and thought there was a bacteriaemia rather than a septicaemia. Dr. H. G. WESTROPP said he had thought at first that the child was only suffering from influenza. She had complained of a headache first and had later vomited. The next day the child was somewhat better, but after two days she became worse, a rash developed, and she complained of pain in her feet, which were very tender. Dr. V. M. SYNGE said he thought the failure of treatment in this case was explained by the pathological findings of internal hydrocephalus, as the serum was not able to get at the seat of the trouble. He referred to Sir James Purves-Stewart's suggestion that in these cases the ventricles should be tapped, and the serum then injected into the ventricles, and also the treatment by tapping the cisterna magna. Dr. W. M. CROFTON thought an autogenous antigen should have been used in this case as being more powerful than serum. Dr. C. MURPHY said that he always injected fresh serum as well as antimeningococcic serum.

Etiology of Cancer.

Dr. JOSEPH T. WIGHAM read a paper on the cause and cure of cancer, dealing with the history of investigations into its nature and causation. Cellular overgrowth might be due to a stimulation of growth or to the removal of an inhibition, and various points of evidence were submitted. Predisposing causes were next considered, including chronic irritation, misplacement of cells or tissues, heredity, and parasites. The most effective of the chemical substances which had been regarded as chronic irritants were those which had a solvent action on fats and lipoids, and much work had been performed on these tars and oils, and on the effect of injecting such substances as Sudan III. The work of Gye and Barnard had revived interest in the possibility of a true living virus being the cause of tumours, but their results had been contested. It seemed also that cancer could be induced in rats by feeding them with the larval forms of several round worms and flukes, and cancer of the liver in man, and possibly of the tongue and oesophagus, had also been attributed to an infection with worms. Passing to the epidemiological investigation of cancer, Dr. Wigham said that Sambon in Italy, other investigators in Holland, and the Health Committee of the League of Nations, as well as other workers elsewhere, had all contributed information showing the variable incidence of cancer; this might lead to further light being thrown on the environmental conditions in which cancer most frequently arose.

The PRESIDENT said that he did not think that a cure would ever be obtained for cancer until its etiology had been discovered. In almost all cases of cancer there were two possible causes. One was its production by an irritating substance or substances; yet many people developed cancer who were never exposed to irritating substances. The other cause was some factor which was apparently inherent in the subject himself. The President believed that there was a third factor, as yet unknown, and he thought that it was a failure to discover this factor which accounted for the inability of some workers to get good results in treatment while others seemed to be more successful.

Dr. W. M. CROFTON referred to the work performed by the Laytons in connexion with sarcoma in rats, which had never been reproduced or refuted, and mentioned that some workers claimed to get good results from putting patients on a diet free from fat-soluble vitamin.

Dr. A. R. PARSONS could not agree with Dr. Wigham that the modern treatment of cancer by radiation was not much better than the old method of treatment by caustics. He thought that in x-ray treatment something much more potent than the old cures was being employed, even though the disappearance of tumours after x-ray treatment was only temporary.

Dr. W. SIEVENSON said that the difference between radiation and the old method of treatment by caustics was that paste killed everything with which it came in contact, and radiation had some selective action. The effect of radium in some cases was extraordinary. He mentioned a case of cancer of the tongue in which, after three days' treatment, the lump had almost disappeared. Radiation differed in its effects in different parts of the body. In some cases healing was stimulated by radiation. He referred to a case of a septic tumour of the breast, in which radiation had been given; the breast had been removed, and the skin had healed by first intention. He thought in some cases surgeons would be able to do a great deal more than they did if the patients were treated by radiation first. Sepsis had much to do with the causation of malignant conditions, and anything which prevented it would help in curing cancer.

Pathology of Lymphosarcoma.

Dr. J. E. DEALE read notes on a case of lymphosarcoma; Dr. J. T. WIGHAM demonstrated specimens. At the *post-mortem* examination it had been found that in and about the head of the pancreas and extending up into the hilum of the liver were several rounded masses up to the size of a walnut, and fairly easily separated from the surrounding tissue. These resembled enlarged lymph glands, and were dead white in colour, with a few vessels or slight haemorrhage. The liver was large, weighing 8 lb., and had a rather coarsely lobulated appearance of the cut surface. Microscopically the liver tissue was divided into masses roughly equivalent to individual lobules, by a tissue composed of a few fibres, a considerable number of large cells with large darkly staining and occasionally multiple nuclei, and a great number of small round cells. The cells of the liver tissue showed regeneration, having large, and occasionally multiple, nuclei. This appearance, although not quite uniform, was that of the greater part of the organ. The spleen weighed 25 oz., and was much congested; the surface showed a number of knobby projections, some of which appeared to be infarcts, composed mostly of necrotic material, with much surrounding haemorrhage. One or two whitish masses were probably tumour growths. The more healthy splenic tissue showed large blood spaces, with much blood. The changes in the spleen were evidently mostly those of chronic congestion, due to the condition of the liver, and perhaps also to the pressure of tumour masses on the splenic vein. The condition was probably one of a diffuse lymphosarcomatous infiltration of the liver, with outlying development in lymph glands.

The PRESIDENT said that the liver was about two and a half times the normal size, apparently due to the diffuse nature of the tumour throughout it. Dr. J. LAIT mentioned a somewhat similar case in which there had been an enlargement of glands about the head of the pancreas. The liver, however, had been free from tumour deposits, whereas the spleen was greatly enlarged by a diffuse sarcomatous growth. It was also a case of lymphosarcoma, but he had considered it primary in the glands with secondary manifestation in the spleen. Dr. A. R. PARSONS said it was very unusual to find such a marked polymorphonuclear leucocytosis in a case of lymphosarcoma.

Reviews.

GASTROSCOPY.

Practical Gastroscopy[1] is the title of a monograph by Dr. JEAN RACHET of Paris, translated into English by Dr. IMIANITOFF of Brussels. After a short introduction the subject is surveyed from the historical aspect, and it is astonishing to find what an amount of work has already been done; the extent of the literature is shown by the annexed bibliography. Most of Rachet's observations were made in Dr. Bensaude's clinic at the Hospital St. Antoine, Paris. A special type of instrument is fully described, and the exact method of introducing it into the stomach; this evidently calls for a considerable amount of care and skill, and, even so, in many cases the examination cannot be completed; in a series of sixty consecutive cases failure occurred in fifteen, owing to malformation of the mouth and neck or to psychic reactions aroused in the patient. The author also points out that great care must be used in selecting suitable cases, and that it cannot be looked upon as a routine method of examination. The results of gastroscopy are next described, and a final chapter deals with the conclusions that can be drawn.

In discussing the general principles involved it is admitted that gastroscopy is an exceptional method of exploring the stomach, and comes after clinical investigations and x-ray examination, but it is claimed that it should come before an exploratory laparotomy. It can only safely be carried out by carefully trained specialists, and although any positive evidence discovered is of value, a negative result is of no practical value inasmuch as the examination does not permit a view of the whole stomach.

The book is very well presented and contains many excellent diagrams, drawings, and reproductions of radiographs. All those interested in the subject will find it of considerable value from many points of view, and it brings the subject well up to date.

FIRST AID IN MATHEMATICS.

NOBODY doubts the value of the mathematical tool in scientific research; sooner or later, most people who do any intellectual work at all are brought up against some equation or formula, and many of them wish to understand how these formulae are constructed. Hence there is a steady demand for introductions to mathematics. Many great mathematicians have tried to supply the demand. In England, De Morgan, Clifford, and Whitehead all tried their hands, and the name of less famous men who have written introductions to mathematics is legion. Messrs. Caradog Jones and Daniels are the latest interpreters between the professional and the amateur. There is a certain analogy between the study of a language and the study of mathematics, and perhaps some disappointment would be saved if this were realized. If one discovers the need of a knowledge of, let us say, Persian, to satisfy some intellectual curiosity (we purposely choose a language which few Londoners are in the way of learning colloquially) one will probably obtain a grammar, learn the alphabet and the elements of accidence and syntax, and then tackle an easy book with a translation. What nobody will expect is, by reading a grammar, to become a master of the whole Persian literature or to undergo so strange a metamorphosis as to be turned into a "Persian." But many people do seem to expect that the perusal of a manual ought to make them free of the whole literature of mathematics and, finding this is not so, are apt to conclude that mathematics are "beyond them." In order to encourage such readers, the tendency of modern introducers is to illustrate their arguments upon data likely to interest particular classes of investigators. Many such books have been written for chemists, and Dr. W. M. Feldman recently wrote one for medical men. Messrs. Caradog Jones and Daniels have had specially in mind persons interested in economics and statistics. Their little *Elements of Mathematics*[2] can be recommended as a quite readable introduction. To medical readers the last part of the book is not of special interest and, for most readers, the first three chapters are perhaps a trifle diffuse. The wording of page 112 is, we think, open to criticism; it is best to restrict the use of the term "convergent" to series consisting of an infinite number of terms. It is, however, very easy to criticize such a book and very hard to write one. We think this is essentially a good book, and can recommend it.

THE FIVE SENSES.

IN *Les Cinq Sens*[3] Dr. CABANÈS has gathered together an immense number of notes and anecdotes about the senses of hearing, taste, sight, and smell. The curious customs of sundry tribes of men, ancient and modern, which are described, are connected not only with the five senses, but also with all the organs accessory to each. For the sense of touch the reader is referred to an earlier volume,[4] in which, however, not much is said about the actual sense of touch, though many pages are devoted to the hands. The use of fingerprints in the identification of criminals is mentioned, its origin in the investigations of Francis Galton, and the methods by which the prints are obtained. To be left-handed is said to be a sign of inferiority, but Dr. Cabanès urges the cultivation of ambidexterity, notwithstanding a caustic remark of Malgaigne about an ambidextrous surgeon. On the subject of fingernails we are told that both Napoleon and his "torturer," Sir Hudson Lowe, were in the habit of biting their nails; and that in Spain a subject once set for a thesis in medicine was whether it was necessary for health to begin by cutting the nails of the right hand or of the left, and whether the thumb should be taken first or the little finger.

An account is given of the various disfigurements of the external ear by rings, plugs of wood, and what not; the removal of the ear in malefactors; the story of the narrow escape of Daniel Defoe from losing his ears in the pillory; and the discovery of artificial ears in Egyptian mummies. Under taste are included notes not only on strange perversions, such as those of the earth-eaters, of cannibals, and of polyphages, but also on beliefs in the properties, therapeutic or poisonous, of the saliva, the practice of amputation of the uvula in children by Persian barbers, and hypotheses about the use or otherwise of the tonsils in singers. In connexion with sight, methods of beautifying the eyebrows amongst the Romans by joining them together by pigments are mentioned; and there is a note to the effect that the Patagonian woman goes to the other extreme by practising epilation of the eyebrows. About the nose many anecdotes and superstitions are recorded. Thus it appears that M. Bernard attributes to the size of Zola's nose the invention of a language of smells in that author's novels. English readers may be somewhat surprised at some of the customs Dr. Cabanès states to exist in this country. Thus English coquetry is said to be gratified by a hairdresser who sews hair of an approved shade into the edge of the eyelids, and curls the new lashes with silver curling-tongs. In England, if you wish to scoff at anyone, you cry, "To nose, to nose" (*Au nez, au nez*). Perhaps there is some confusion here between the errand-boy's method of indicating contempt and the meaning of the vulgarism "to nose." And is there really a sect of English botanists called anthophages, whose habitual diet is cauliflowers and artichokes? However, with allowances for his difficulties with foreign customs, of which he has only hearsay evidence, Dr. Cabanès's books are an entertaining collection of wild and weird beliefs and habits.

URINARY SURGERY.

MR. W. K. IRWIN, F.R.C.S.E., has issued, with the title *Urinary Surgery*,[5] a new edition of his book *Surgical Urology*. The alteration has been made because it had been objected that the old title was ambiguous and did not define accurately the scope of the work. The book, though revised and enlarged, presents the same essential features. After dealing with anatomy and the examination of the patient, the seven chief symptoms of genito-urinary lesions form the subjects of separate chapters; special attention is paid to their causation and treatment. These chief symptoms have been grouped under the following headings: incontinence of urine, frequent micturition, difficult micturition, retention, pain, haematuria, and pyuria. In the author's opinion, and we are inclined to agree with him, this arrangement, although it necessarily leads to repetition and renders the book less convenient as a work of reference, corresponds more exactly with the clinical conditions encountered, and furnishes the practitioner with information of great practical value in his everyday work. Since it is intended for those called upon to weigh the pros and cons of operation rather than to carry out the operation itself, the details of operative procedure are omitted and only a brief sketch given of the surgical aspect of the subject. The book is clearly written and is practical in its outlook. The fact that it is occasionally dogmatic in its tone and that it avoids any discussion of theory or debatable matter is an advantage rather than a shortcoming.

THE EXCITABILITY OF NERVES.

PROFESSOR LAPICQUE'S monograph on excitability as a function of time[6] deals in the first instance with Du Bois-Reymond's law of excitation, which was based on the idea that the response observed in muscle on electrical stimulation is not dependent on the absolute value of the density of the current, but on the variation of its value from instant to instant. Although the law has been shown to be untrue and it is now known that the current excites, not by its variation, but by the first instants of its passage, Du Bois-Reymond's authority dominated for more than half a century. This lengthy usurpation is attributed by the author to a certain shyness exhibited by physiologists towards mathematics, and he emphasizes the importance of a familiarity with mathematical language if errors are not to remain undetected. Making an unstinted use of mathematical language, he passes in review the progress of thought from Du Bois-Reymond to Weiss, he discusses Pflüger's work on electrotonus, von Bezold on the latent period, Fick on the muscle of Anodon, Brucke on curarized muscle, Engelmann on the contractions of the ureter, Hoorweg on excitation by condensor-discharge, and Waller's characteristic of excitation. In the second part of the work the quantitative data afforded by experiment are discussed, while the third part is devoted to theoretical considerations and an attempt to establish a physical theory of *electrical stimulation*, taking as a starting-point the conception of Nernst and ending with his own researches and his conception of chronaxy or excitability expressed as a mathematical constant of time.

The main object of the book is indeed to explain chronaxy, and in the fourth part the author has given an account of the subject in language which can be comprehended by the non-mathematical. When a progressive current, uniformly increasing in intensity, is led into a muscle, the relation between the intensity and the duration of the stimulus, calculated at the threshold of contraction, can be expressed by a curve of definite form, the abscissa marking the duration and the ordinate the intensity. Beyond a certain duration the two magnitudes become independent, the intensity remaining constant whatever the duration of the stimulus, and the liminal intensity being represented by a straight line parallel to the abscissa or axis of time. Lapicque calls this intensity the rheobase. With currents of shorter duration the intensity and the time are definitely related; the shorter the duration the greater the intensity required to reach the liminal contraction and the steeper the curve. Now the relation referred to differs in different muscles, but it is found that the curves have the same form, and by adjusting the size of the diagrams the curves of two different muscles—for instance, the rapidly contracting voluntary muscle and the slowly contracting smooth muscle—can be made to coincide. In this case the abscissa or axis of time will indicate two series of durations, the unit of time employed for the rapidly contracting muscle being necessarily much smaller than that for the smooth muscle. If, now, a definite point in the curve is taken (Lapicque takes the point corresponding to twice the rheobase), the two readings on the abscissa corresponding to the ordinate of the point furnish a measure of the relative excitability of the muscles, or their chronaxy.

Lapicque mentions many directions in which the determination of the chronaxy may be employed in research. For instance, the auricular and ventricular myocardium exhibits a definite chronaxic relation to the auriculo-ventricular bundle, and poisons which affect the transmission of excitation between auricle and ventricle have a graduated activity corresponding to the chronaxy. It appears that variations in the dimension of the rheobase afford a means of studying the effects of poisons on the muscle. Further, the notion of chronaxy is applicable not only to the excitability of muscle, but also to that of every species of vital tissue.

NOTES ON BOOKS.

WISDOM, born of long experience and careful observation, is so rare in these days when the majority of our youth are being hurried along by short cuts to the acquisition of a specious knowledge, that its utterance is sure to be received with general acclamation. It is not surprising, therefore, that Dr. ROBERT HUTCHISON has been compelled to arrange for a second edition of his *Lectures on Dyspepsia*[7] only a couple of years after the original publication of the volume. There are few problems so puzzling to the general practitioner as the diagnosis of chronic abdominal disorders, and there are few books that will be so helpful to him as the present volume of lectures. We feel sure that all who read it will be grateful to the author.

Mr. J. W. N. SULLIVAN has two gods. Their names are Relativity Theory and Quantum Theory. In *Gallio, or the Tyranny of Science*,[8] one of the series of *jeux d'esprit* published under the general head "To-day and To-morrow," Mr. Sullivan sets forth his religion. We gather that his gods have the merit of being incomprehensible by the multitude, and that their origin displays the loftiness of human imagination. It appears also that Beethoven was an angel of light, while Freud is a minion of the Prince of Darkness. The idea that there is a conflict between science and art or mysticism rests upon an old-fashioned conception of the status of physics. Out-of-date science leads to conclusions which are depressing to the artist or the poet. The conception that the real universe is a four-dimensional world of point-events with a certain minimum amount of structure breaks up old habits of thought and rouses enthusiasm in the soul of the artist. As the conception of "purpose" in the universe seems to suppose a process in time, it may be a totally irrelevant idea when applied to reality. Could anything be more satisfying to a poet? Especially when he remembers how little we know of the possibilities of development of the human consciousness. After saying on one page that the proper attitude to-day to man's place in nature is one of bewilderment and humility, Mr. Sullivan tells us on the next that he has shown that the philosophy which regards man as a meaningless accident in an alien universe receives no support from modern physics. Unfortunately, however, neither philosophy nor modern physics seems to give Mr. Sullivan an answer to his problem. All we learn is that a conclusion "cannot be transcended by a logical process, but only in virtue of a mystic experience." The old materialistic outlook, says Mr. Sullivan, is still active in many branches of science; but in the stuff of our ordinary experience, such as psychology, we do wrong to accept the obviously absurd for fear it cannot be as silly as it looks.

[5] *Urinary Surgery*. By William Knox Irwin, M.D., F.R.C.S.E. Second edition, revised and enlarged. London: Baillière, Tindall and Cox. 1927. (Cr. 8vo, pp. viii + 271. 10s. 6d. net.)

[6] *L'Excitabilité en Fonction du Temps*. Par Louis Lapicque, D.M., D.Sc.Paris, LL.D., D.Sc.Oxford. Les Problèmes Biologiques. Paris: Les Presses Universitaires de France. 1926. (6 × 9½, pp. 371; 79 figures. 45 fr.)

[7] *Lectures on Dyspepsia*. By Robert Hutchison, M.D., F.R.C.P. Second edition. London: E. Arnold. 1927. (Cr. 8vo, pp. 200. 6s. net.)

[8] *Gallio, or the Tyranny of Science*. By J. W. N. Sullivan. To-day and To-morrow Series. London: Kegan Paul, Trench, Trubner and Co., Ltd.; New York: E. P. Dutton and Co. 1927. (Fcap. 8vo, pp. 96. 2s. 6d. net.)

A great deal of psycho-analysis, he thinks, is so silly that only people deficient in common sense and lacking in a sense of humour could have invented it. From this it will be seen that Mr. Sullivan, as a priest of the new religion, does not feel bound to adopt the attitude of bewilderment and humility.

A manual on the *Principles of Physical Chemistry for Medical Students*[9] has been prepared by PHYLLIS KERRIDGE, M.Sc., who is an assistant in the department of physiology and biochemistry at University College, London. Physical chemistry is a little incongruous to the harmonic group of studies connected with biology, but yet is an essential requisite to medical education. The aim of the author, in recognition of this, has been to gauge carefully what is most necessary as well as sufficient for the medical student's purpose, and to save him from wandering farther afield from his main occupation than necessary. In this aspect the volume has been ably prepared; there is no lack of explanation nor any superabundance of words, and the book appears to give the student a very high rate of return for his effort of study.

Under the title of *The Fifth Avenue Hospital Clinics*[10] are collected reprints of articles previously published by members of the staff of this hospital in New York. The volume also includes informal addresses read at meetings of the staff in 1925.

Lovers of Surtees and Beckford will find equal pleasure in reading *Letters on Hunting and the Management of Hounds*[11] by "Scrutator," a well known west country squire, by name K. W. Horlock, who for many years was master of foxhounds. The book is full of hints on the management of hounds, and contains all that information which only one who has practical experience of mastership can furnish. It is admirably written, and is sprinkled with amusing anecdotes. In short it is a book that should be in every hunting man's library.

PREPARATIONS AND APPLIANCES.

Anti-gas-gangrene Serum.

AN anti-gas-gangrene serum (W) (*B. welchii*) has been prepared by Messrs. Burroughs Wellcome in view of the importance attaching to the presence of the causative organism of gas gangrene in some cases of peritonitis and acute intestinal obstruction. During the war the prevention and treatment of gas gangrene was, of course, a matter of everyday importance, and promising results were then obtained with serums. Suitable doses of the present serum are 80 c.cm. intramuscularly or 40 c.cm. intravenously.

VICHY, AND ITS WATERS.

BY

SIR JAMES BARR, M.D.

VICHY is situated near the geographical centre of France. The medicinal properties of its waters have been known from time immemorial, but the first successful impetus to its popularity was given by Napoleon III, who, with the Empress Eugénie, made frequent visits for treatment from 1861 to 1866. Since then the town has steadily grown in size and importance, and it is now the most popular health resort in Europe. Over 130,000 invalids come here for treatment every year—of these a very considerable number have paid several previous visits.

We may now inquire what solid foundation there is for this popularity. It is true that we find here all the amenities of civilized society, but these attractions are no greater, nor perhaps as great, as those to be found at many other health resorts. After careful observation one is forced to the conclusion that the great bulk of the visitors come seeking health or a restoration to health, and if they were disappointed they would not repeat their visits so regularly.

The town is situated on the right bank of the river Allier—a large and rapid stream; the domestic water supply is ample, potable, and is said to be about the best in France. There are forty mineral springs, but only about twelve are in common use. These waters are free, and are freely used, though a free gift is not always appreciated. However, everyone seems to take the waters religiously according to the prescription of his medical adviser. Almost on arrival everyone is advised to consult a local medical man, and it is difficult to get a bath of any kind at the Grand Thermal Establishment except on a medical prescription. This is a very wise precaution, as nothing could more readily detract from the reputation of the place than the indiscriminate use of the baths and waters. Vichy is well supplied with a large number of able medical men, to whom the success of the place is in no small measure due.

The Grand Thermal Establishment covers an area of nearly eight acres, and here baths of every description can be had. The mechano-therapy department is the best equipped that I have ever seen. The director, Dr. Haller, tells me that during the height of the season the clientele number 500 daily. This gives some indication of the number of damaged joints to be found in Vichy.

Dr. Félix Ramond of Paris in a recent article gives a glowing account of the mineral waters of Vichy, how they are formed deep down in the crust of the earth by the union of hydrogen and oxygen given off from the incandescent mass of metallic oxides. As the vapour gives off its latent heat it becomes condensed into water, which travels in various cracks of the earth to the surface, absorbing various salts in its passage. The waters must certainly start from a hot area as, notwithstanding all the cooling process in the transit, the Chomel source records a temperature of 109° F. on reaching the surface. Personally I am more interested in the physical and chemical properties of the waters than in their origin *in inferno*. There are forty-three million bottles of Vichy water exported annually. The chief sources for export are the Célestins, the Grande Grille, and to a less extent l'Hôpital. I presume these waters are more stable than some of the others, and are thus not so apt to alter in transit. For use at the source the Chomel is most frequently prescribed. I shall therefore deal exclusively with it. It is the warmest, the temperature being about 104° to 109° F., and is quite palatable. The composition in grams per litre is: sodium bicarbonate, 5.6; potassium bicarbonate, 0.35; lithium bicarbonate, 0.012; calcium bicarbonate, 0.36; magnesium bicarbonate, 0.07; ferrous bicarbonate, 0.001; sodium chloride, 0.57; sodium sulphate, 0.28; silicon oxide, 0.06; free carbonic acid gas, 0.97. The salts seem to be in an active state of ionization—anions and kations. The electric resistance is eighteen times less, and the electric conductivity eighteen times greater than ordinary tap water. The water is isotonic with the blood serum, to which it supplies an abundance of buffer salts. On this account the normal hydrogen-ion balance of the blood is easily maintained without any incessant strain on the regulative mechanism of the body. As there is an abundant supply of free ions in the waters, large doses should not be required; in fact, this is corroborated by the experience of the physicians, who find that repeated small doses are more efficient than one large dose.

The bipolar theory of living processes which has been long held by many, and which has been recently adopted by the great American surgeon Dr. Crile, is in harmony with what I have written. If Dr. Crile be correct, as I believe he is, that the brain is the positive and the liver the negative pole of the principal electric circuit of the human body, then the liver regains the importance which was formerly attached to it in the human economy. The preservation of the functions of the liver is very essential for health, and this object is well attained by the treatment at Vichy. The principal diseases which are amenable to the Vichy treatment are functional and organic disorders of the whole of the digestive and urinary tracts, diabetes, metabolic troubles, diseases of the spleen, gout, rheumatism, and different forms of arthritis, uterine troubles, and numerous skin affections.

As I am anxious not to overstate facts I have submitted this paper to Dr. Monod, one of the leading Vichy physicians, and he has not found any fault in it.

A large number come here every year to recuperate after the dissipations of the London season, and as the new Pullman service has brought Vichy within fourteen hours of London, still greater numbers are expected this year.

British Medical Journal.

SATURDAY, JUNE 11TH, 1927.

PUBLIC CLINICS AND MEDICAL TRAINING.

AT its meeting in April the Council of the British Medical Association, approving a report with regard to orthopaedic clinics, pointed out that one of the dangers attending the establishment of such clinics is "the withdrawal of a large number of cases of a special type from those hospitals in which medical education is carried on in connexion with medical schools, so adding to the difficulties of securing an adequate knowledge of such conditions among medical practitioners in general." Last month the Council of the Society of Medical Officers of Health adopted a report on the instruction of medical students in ante-natal conditions and infant hygiene, embodying the results of an inquiry it had made as to how the requirements of the General Medical Council with regard to such instruction, and examinations in respect thereto, were being carried out by medical schools and qualifying bodies. These facts are evidence of increasing anxiety as to the situation which is rapidly developing, or at least may easily develop, in connexion with the multiplication of county or municipal medical services and the limitations which these tend to place on the full training and experience of the medical practitioner, both before and after graduation, which is necessary for the well-being of the public. This anxiety is by no means premature. There are now no fewer than seventeen departments, spheres, or directions of clinical activity for which provision is made in this sectional way under the auspices of local authorities. Some of these cover an extensive field of medicine; and in some there has arisen the ominous and increasingly insistent suggestion that the public needs can best be met by authorizing the placing of responsibility for giving advice and treatment upon persons other than qualified and registered medical practitioners. For instance, we have heard it claimed that midwives are quite capable of dealing with ante-natal conditions; that school nurses, under the purely nominal supervision of a medical officer, may safely be left to treat what are called the "minor ailments" of school children; and that dentists, rather than medical practitioners, should be entrusted with the administration of certain classes of anaesthetics. The pretensions of some opticians, now being pressed with a good deal of parliamentary sympathy, are especially dangerous. They are asking that the State should officially recognize them and register them as being the most skilled, if not the only legitimate, practitioners in an extensive field of ophthalmic treatment, and that their certificates within this field shall be, under statutory compulsion, recognized by "any local or central authority or Government department in any part of Great Britain."

Two interlocked vicious circles are, in fact, being established. There is danger that medical students may be imperfectly instructed in some part of their work owing to the withdrawal of special types of case to the clinics of local authorities, and there is danger that it may become difficult properly to staff those clinics owing to imperfect training of medical students. There is danger that unqualified persons may be officially recognized in certain fields of medical work owing to alleged insufficiency in the supply of competent medical practitioners, and there is danger that a progressively smaller number of qualified medical practitioners will cultivate those fields owing to their remunerative clientele being seriously diminished by the official recognition of the unqualified persons. If Parliament, the Government departments concerned, the local authorities, and the powers within the medical profession are wise, however, it is not yet too late to avoid these dangers.

There is no pretence, of course, that a medical student, on passing his qualifying examination, has become a wise practitioner, or is specially skilled in any particular branch of his profession; but his training and knowledge should even then be such that he can safely undertake many kinds of medical and surgical work, that after relatively short further experience he can properly assume considerable responsibility in one or other of the local government medical services, and that he will be in a position fully to profit by increasing experience, whether in such service or in private practice. It is the business of the General Medical Council, so far as possible, to see that a suitable kind of training and the requisite degree of knowledge are secured to the student, and it is the business of the medical schools and examining bodies to give the training and test the knowledge in accordance with the requirements of that Council. In the year 1922 the General Medical Council prescribed a readjustment of the medical curriculum, to come into force at the beginning of the following year. In this readjustment, among other things, increased emphasis was placed upon sufficient opportunity being afforded for the study, both theoretical and clinical, of those subjects which are now so essential in connexion with the treatment centres of a local authority, such as ophthalmology, venereal diseases, orthopaedics and mechano-therapeutics, infectious fevers, anaesthetics, ante-natal conditions, and infant welfare. In any judgement upon present conditions it must be remembered that no qualifying examination based upon this readjusted curriculum can take place until next year, and that it is not unreasonable to expect that, as the result of the maturing of this course of study, recruits to the profession will be found thereafter to be more abundantly proficient in these respects. Time has now been given for the universities, schools, and examining bodies to adjust themselves to these requirements, and we understand that an inquiry by the General Medical Council as to how far this has been done is now almost completed. It is expected that the results of this inquiry will be made public either in November next or early next year. In view of this it is not surprising that the inquiries previously referred to as having been made by the Society of Medical Officers of Health should have met with a very partial response. It is not unlikely that the bodies of whom inquiry was made regarded this rather as the business of the General Medical Council than of that society.

It is unfortunately true that a perfect prospectus and syllabus may mask very imperfect educational methods; but it is also found that a prospectus which is open to adverse criticism is in practice not incompatible with really full and excellent teaching. However this may be, the requirements have been laid down, and proceedings are being taken to see that they are actually fulfilled. Where a municipal centre or clinic is being conducted within a teaching hospital there should be no real difficulty in the student being instructed at such a centre, under conditions which

will allow of the prime purpose of the centre being respected. Where the municipal or county provision is made elsewhere, it behoves the university or teaching hospital and the local authority to agree upon suitable facilities being allowed whereby the best use will be made of such material as is available for teaching purposes. Sufficient attempt has not yet been made in all cases to do either of these things.

The method of staffing such clinics as are not within teaching hospitals, and the use that is made of them for gaining post-graduate experience, are important alike to the public and to the profession. If they are staffed by whole-time medical officers, the experience which they afford is so far withdrawn from the sphere of private medical practitioners, and this has an immediate and adverse reaction upon the competence of such practitioners to deal with similar conditions among the general public. It is the policy of the British Medical Association that this work should, wherever possible, be done by the private practitioners of the locality under suitable arrangements and with the general administrative supervision of the medical officer of health; the character of the work is such that as a rule it can be done at least as effectively by such practitioners as by a whole-time officer. Where for some reason such an arrangement cannot be made, the practice of the clinics should certainly not be closed to such practitioners as wish to observe it. No organization can assist the making of such arrangements as these more powerfully than the Society of Medical Officers of Health, and it is to be hoped that, in the general interest, that society and its individual members will use their influence, both to secure for teaching purposes the opportunities afforded by clinics, and to facilitate the private practitioner obtaining to the fullest extent the advantage of the occasions for gaining experience which they offer. In this way fields of practice which are at present threatened will be preserved to the profession, much to the advantage of the public health.

OPTICALLY ISOMERIC SUBSTANCES IN BIOLOGY.

ONE of the last, if not the last, of the contributions to current medical discussion made by the late Professor A. R. Cushny was contained in the Dohme memorial lectures delivered at the Johns Hopkins University School of Medicine in 1925. Early in the following year he died, to the great loss of scientific medicine. The Dohme lectureship was founded in memory of Mr. Charles E. Dohme, a member of a chemical firm in Baltimore, who, Professor Cushny said, in the preface to the volume in which his lectures have now been embodied,[1] was a man "of wide views and interests, who recognized the importance to industry of the advance of scientific investigation." The purpose of the lectureship is to promote the development of a more intimate relation between chemistry, pharmacy, and medicine, and it will be agreed that the choice of Professor Cushny as spokesman for pharmacology was singularly happy. Pharmacology, in so far as it is the handmaid of medicine, may properly be described as an applied science. Nevertheless, its roots are deep in the academic problems of pure chemistry and physiology, since its enterprises must ultimately be directed towards relating the physiological action of substances to their chemical constitution.

Professor Cushny took for his subject the specific action of optically active isomers. No conception of the structure of matter has so enlightened and confirmed confidence in the atomic theory as has that of the spatial orientation of valency forces and its corollary the optical activity of the asymmetric carbon atom. The success with which it has been applied to the most complex problems in chemical constitution has lifted the atomic theory from the position of a convenient language for the expression of reaction to a plausible projection of the actual structure of matter in space. The phenomenon, at the same time, occupies a unique place in the chemistry of living systems, since it marks the one complete failure in the attempt of the organic chemist to imitate the activities of living matter. Whilst the factories of the living cell continue to exhibit a high degree of selectivity in the elaboration of optically active forms the chemist has failed completely to effect an asymmetric synthesis of a stereo-isomer.

This failure is fundamental to physiology, as Pasteur recognized when he argued from the asymmetry of vital activities a fundamental asymmetry of life itself. Professor Cushny took up the story and reviewed the evidence, now more complete, for asymmetric selectivity in biochemical phenomena, in the metabolism of the whole organism, in the pharmacology of isolated organs, and in the field of enzyme activity. He pointed out that whereas the proofs of biological specificity are overwhelming, it is by no means certain that the ability of living systems to discriminate between optically active forms is absolute. On the contrary, the distinction probably represents only a relative difference in the velocities of controlling chemical processes, though these are, in general, so great as to lead to pronounced physiological contrasts.

The examples to which the fullest consideration was given are those that were disclosed by Cushny's own work on the pharmacological action of the hyoscyamines, hyoscines, and adrenalines. The results are of great interest alike to the biologist and to the chemist. In conclusion, Professor Cushny tentatively approached the fundamental problem of the physiological significance of these phenomena. Time will probably justify his inclination to find their explanation in some manifestation of asymmetric surface forces, although no clear case has yet been demonstrated of a specific asymmetric adsorption. The experiments of Porter on the selective staining of wool by optically active dyes have been questioned and require confirmation. The analysis which Professor Cushny made of the relation between the constitution of the drugs studied by him and the possible chemical characteristics of their receptors in the cell are of real interest when read in the light of recent views of the chemical structure of surfaces and the orienting effect of surface forces.

Professor Cushny's lectures breathed the wide vision and deep insight of a great investigator of vital phenomena.

THE new form of death certificate which was, by the courtesy of the Registrar-General, discussed by the Medico-Political Committee of the British Medical Association at its last meeting, is now ready, and will come into use on July 1st. This will entail certain modifications in the procedure of death certification, designed to ensure greater accuracy in the national record of causes of death. A full account of the details and object of the new form will be given in an early issue of the BRITISH MEDICAL JOURNAL.

[1] *Biological Relations of Optically Isomeric Substances.* By Arthur R. Cushny, M.D., F.R.S. London: Baillière, Tindall and Cox. 1926. (Demy 8vo, pp. ix + 80; 4 figures, 7 tables. 9s. net.)

EXPERIMENTS ON DOGS.

A MEMORANDUM by the Medical Research Council on the Dogs' Protection Bill has been issued as a White Paper.[1] In the first paragraph the Council recalls that it is a body charged with the responsibility of applying moneys provided by Parliament and from other sources to the promotion of medical research, and states that the proposals of the bill "would place an insuperable and permanent barrier across some of the chief paths of progress in this work." It then proceeds to set out special reasons which make it necessary that dogs should not be excluded from that service to mankind in which animals have so greatly aided the advancement of medical science. "It is," the memorandum states, "beyond dispute that the present-day science and art of the physician and surgeon have been founded in large part upon the experimental use of dogs in the past. It has been by the use of dogs that the chief foundations of our knowledge of the processes of digestion, the circulation of lymph, the work of the heart, and the circulation of the blood have been laid. Large and essential parts of our knowledge of the science of feeding are based upon the results of trials made in the feeding of dogs. The work of the surgeon, whether upon the brain and spinal cord, or upon the intestine, or upon the chest, has been made possible by experiments upon dogs. Methods of life-saving, as by the transfusion of blood, or in the resuscitation of the apparently drowned, have been worked out chiefly by trials with dogs. Important parts of our knowledge of anaesthetics and their safe administration, and of the actions of many kinds of drugs, have been gained by the experimental use of dogs. There is no medical practitioner who does not use in his daily work information which he owes to experiments on dogs. If he is to understand the meaning of such common symptoms as palpitation, breathlessness, giddiness, fainting, and many other forms of distress, if he feels a pulse or listens to the chest, if he transfuses his patient with blood, or employs rectal feeding, he is making wholesale use of knowledge derived from experiments upon unconscious dogs." In the next paragraph the reasons which have made it necessary, and will always make it necessary, to use dogs for some of this experimental work are set out. Mention is made first of considerations of size, and it is observed that in this respect the only animals giving a practical alternative are the sheep, the pig, the goat, or the ape. The dog, unlike these animals, can be kept completely healthy and comfortable in a laboratory, and is not afraid of close and friendly observation. His long domestication has assimilated his natural diet to that of man, and many of his bodily structures provide the nearest approximation among available animals to those of man. The study of diet, and the collection and chemical examination of the excreta, can be carried out readily in the dog, and the results are in the main directly applicable to man or the child. Dogs are, therefore, used for certain experiments, though only in a small minority of instances; but it is plain, the Medical Research Council holds, that the selection of the animal most fitted for the special purposes in view must be left to the discretion and skilled knowledge of the workers in medical science. The Council then goes on to give some instances of recent advances in knowledge due directly to experiments on dogs. In this connexion it refers to rickets, disorders of the teeth, the effects of alcohol, to the study of diseases of the heart and circulation, and to diabetes. The members of the Council, speaking with knowledge—in the case of many of them with intimate knowledge—of the actual conditions under which experiments upon dogs are performed in this country, assert confidently that in the vast majority of such experiments no pain at all is inflicted. The experiment or the observation is either made wholly under an anaesthetic and death produced without awakening, or the experiment is a feeding experiment. In a small minority of cases, where for special reasons and under a special certificate recovery after operation is allowed, there is rarely any condition of pain as distinguished from discomfort. A paragraph of the memorandum is devoted to the benefit to dogs derived from research; special reference is made to the study of distemper, to the prevention and treatment of spirochaetal jaundice, and piroplasmosis (malignant jaundice) in dogs, by which the lives of practically 100 per cent. of affected dogs are saved, while 80 per cent. die if left untreated. Moreover, the veterinary surgeon has gained from the experimental studies of physiologists the knowledge that dogs can be deeply anaesthetized with safety, so that operations on valued dogs can now be performed painlessly which were previously done on the conscious animal. The kind of propaganda by which most of the support gained for the Dogs' Protection Bill in and out of Parliament has been obtained is condemned; statements are made which are grossly misleading, and conceal the central fact that operational experiments are only performed under deep anaesthesia, and with the strictest precautions for the avoidance of suffering; the enormous diminution of bodily pain and mental suffering which the experimental use of dogs or other animals has already brought about is persistently belittled or denied. In this way absolutely groundless distress has been caused to very many unselfish right-minded men and women who have believed the tales or suggestions of cruelty made by the propagandists. Finally, the memorandum deals with the danger that stolen dogs may be sold for the purposes of experiment; this risk, it is pointed out, would become negligible if some of the many thousands of stray dogs that are unclaimed or abandoned were made available for painless experiment. The Council therefore urges that the Dogs Act should be amended by the repeal of the section which prevents the police from transferring stray and unsaleable dogs remaining unclaimed by any owner to a suitable authority established by the Home Office for the purposes of *experiment* under the existing law and Home Office regulations. It is reported that 50,000 dogs are destroyed annually in London under police regulations; these dogs either have no owner or their owners do not care enough about them to make inquiries when they are lost. The law should be so altered as to allow part at least of the now useless annual massacre of dogs to be turned to the permanent benefit of mankind and other animals. The memorandum is signed by the Earl of Balfour as chairman, by Lord Mildmay of Flete as treasurer, by Sir Walter Fletcher as secretary, and by all the other members of the Medical Research Council. It will be seen that the Medical Research Council is in complete agreement with the British Medical Association, and endorses the arguments it has put forward.

[1] The memorandum is addressed to the Lords of the Committee of the Privy Council for Medical Research (the Lord President of the Council, the Home Secretary, the Secretary for Dominion Affairs, the Secretary for the Colonies, the Minister of Health, and the Secretary for Scotland). It is a *command* paper (Cmd. 2859) presented to Parliament by the Lord President, and can be obtained from H.M. Stationery Office or through any bookseller. Price 2d. net.

INHERITANCE OF TUBERCULOSIS.

DR. PERCY STOCKS, medical officer of the Galton Laboratory at University College, has now published in the current (April) number of the *Annals of Eugenics* the fresh evidence obtained at the laboratory on the inheritance factor in tuberculosis. The work on which this paper was based was done partly by Professor Karl Pearson, but mainly by Dr. Stocks. Its object was to test views expressed by Sir Arthur Newsholme and others in support of Robert Koch's statement that "predisposition is merely proximity to the bacillus," and to strengthen the case for the hereditary

factor in tuberculosis. Carefully collected family histories of over 4,000 consecutive patients who attended the tuberculosis institutions in Belfast from 1914 to 1917 were examined, and the prevalence of active tuberculosis in Belfast and among brothers and sisters of patients attending tuberculosis dispensaries was ascertained in sex and age groups. From his figures Dr. Stocks considers that it is justifiable to draw the conclusions that at all ages after 10 years there is a fraternal correlation of the order 0.25 to 0.3; that these coefficients may be regarded as minimal values, and do not represent the full hereditary intensity; and that the coefficients show no consistent tendency to decrease after 10 years of age with advancing age of the pairs, as would be expected to happen if they arose from infection or environmental causes. During the first ten years of life Dr. Stocks thinks that an additional factor must be sought. He admits that this factor might be direct infection between young children, or a common source of infection in the home. The high correlations in early childhood lend support to the efforts that are being made in many European countries to protect infants in tuberculous families from sources of infection during their earliest years. But, as a convinced believer in the inheritance factor, Dr. Stocks advances another explanation, based on the fact that when a young child is reported tuberculous the tuberculosis officer is easily able to examine all its brothers and sisters; whereas with adults the officer has to trust to statements by the patient, who may have very imperfect information on the condition of his siblings in their childhood. While refraining from discussing Dr. Stocks's figures, we may perhaps remind our readers that French observers have been busy with investigations tending to show that a filter-passing virus of tubercle can be transmitted through the placenta.

THE OTHER USES OF X RAYS.

THE last social evening of the session was held at the Royal Society of Medicine on June 3rd, when Sir James and Lady Berry again received the Fellows and guests. The feature of the evening was a short lecture by Dr. G. W. C. Kaye, superintendent of the physics department of the National Physical Laboratory, on the non-medical uses of x rays. He prefaced his subject with a cartoon which he had unearthed from *Punch* of January, 1896, immediately after the publication of Roentgen's discovery. The cartoon showed John Bull confronting the then Kaiser, above a legend which ran: "Thanks to the discovery of Professor Roentgen, the German Emperor will now be able to obtain an exact photograph of a backbone of unsuspected size and strength"—a happy prophetic touch. Another cartoon, in 1923, showed a group of very transparent-looking American gentlemen, on whose persons, however, and among whose belongings certain dark shadows were revealed which had very much the shape of flasks and bottles. Dr. Kaye began the more serious part of his address by exhibiting a copy of the now historical radiograph of the hand taken by Mr. Campbell Swinton at the London Camera Club in 1896, with an exposure of twenty minutes. The skeleton was just discernible. This radiograph was, we believe, that reproduced in the issue of this JOURNAL for January 25th, 1896, shortly after Professor Roentgen had sent to Professor (now Sir) Arthur Schuster, who then occupied the chair of physics in Manchester, the first radiograms to reach England. It must be admitted that, as Dr. Kaye declared, the bones of the hand were barely discernible, but the print, it may be said without any desire to play upon words, foreshadowed the immense advances that have since taken place. How great they are is evidenced by the fact that sharp images of bones are now obtainable with an exposure of 1/100th of a second. One minor application of x rays, Dr. Kaye continued, is in the study of such fragile structures as flowers and shells; here, of course, very "soft" rays, excited by a low voltage, must be used. X rays can also be used to test the genuineness of jewels. Dr. Kaye said that a friend of his recently picked up in Oxford Street what he took to be a paltry trinket, but on subjecting it to x rays he found that the stones were genuine diamonds, for they appeared transparent, instead of opaque, as imitation gems would have done. To complete the story it should be added that he immediately took his find to the police station! The rays are now being applied in Scottish coal fields to determine in samples of coal the proportion of ash. Streaks of ash are shown clearly in a section of coal under the x-ray beam. Large quantities of ebonite are now used for wireless purposes, and it is important that the ebonite should be free from mineral matter; x rays show whether this is so or not. The rays are being applied to the testing of golf balls, to discover whether, as sometimes happens, the core is out of centre; the balls are rolled slowly before an x-ray apparatus, and any distortion of the core is immediately detected, thus preventing subsequent foozles or flukes. The x-ray picture of the electrically heated jacket of the air pilot shows the site of any broken connexion. Clinical thermometers are tested to determine the nature of the glass. They are placed on trays and passed through the x-ray beam, and the least expert watcher can pass the lead glass and reject the soda. The rays are also used in munition factories to detect, for instance, flaws in hand grenades and similar material. It can be shown by x rays whether the parts in a wireless valve are assembled with absolute correctness, and another use is the detection of knots and worm-holes in wood used in aeroplane construction. Art as well as industry is served by x rays. Dr. Kaye spoke of the assistance which x rays can give in testing the genuineness of old masters and of antiques generally. In the early ages of painting there were only eight or nine pigments, all of which are very opaque to x rays, whereas the modern pigments which the chemist has provided are very transparent. Not only can fraud sometimes be detected in this way, but in a genuine old work interesting revelations may be made, and various tentative sketches be brought to light which the artist evidently thought he had erased from the canvas. Dr. Kaye touched upon the science of x-ray spectrometry, and the addition which x-ray analysis had made to our knowledge of the atomic structure of the solid state of matter. The rays had demonstrated, for example, that almost every solid substance in nature showed crystalline form, including such unlikely materials as rubber, cellulose, the tooth, and the finger-nail.

THE BIRTH OF A PROFESSION.

IN an address delivered a short time ago to the Institute of Chemistry of Great Britain and Ireland, on the growth of the profession of chemistry during the past half-century, Mr. A. Chaston Chapman said that fifty years ago scientific or pure chemistry was not always on the best of terms with professional chemistry. Among those who followed chemistry as a profession or means of subsistence certain reprehensible practices were quite common, such as issuing laudatory reports for unrestricted publication, and touting. Moreover, much of the practice of the day was in the hands of men with insufficient training, so that work under such important statutes as the Sale of Food and Drugs Act of 1875 often found its way to persons with a meagre knowledge of chemistry. The foundation of the Institute of Chemistry in 1877 was the first step towards placing the profession of chemistry on a proper basis. It established professional cohesion; it offered the public a means of distinguishing properly trained men from imperfectly

trained men; and it introduced a code of professional ethics. The result has been, according to Mr. Chapman, that the general average of income for chemists is better than the average in other professions. Mr. Chapman dwelt on the importance of the chemist to the State in the work of various Government laboratories, and in the administration of such Acts as the Food and Drugs Acts. He showed how important chemistry is in most modern industries. He insisted on the need for the private or consulting chemist. In this connexion, as a convinced believer in individual effort, Mr. Chapman deplored the tendency to stamp out the independent worker. He expressed regret that whole-time municipal chemists were replacing "outside" men, and that large, and even small, industrial concerns now frequently employed their own resident chemist. In conclusion, Mr. Chapman pointed out that chemistry is one of the basic sciences, which has profoundly modified almost every department of human activity, and has made happier the daily life of every individual.

FREE POST-GRADUATE EDUCATION.

THE Medical Society of the State of New York is offering graduate education, without cost, to every physician in the State. Dr. Charles A. Gordon, chairman of the Education Committee of the medical society, has recently published an account of the origin and objects of this movement.[1] In the belief that responsibility for graduate education rests on organized medicine, which should assume leadership in the solution of public health problems, the Medical Society of the State of New York decided to carry education to those who were unable to leave their homes. During the past two years clinical lectures and demonstrations have been given in fifty-one of the sixty-two counties of the State by fifty or sixty teachers from the larger cities. In return for this service the teachers receive "the thanks of the committee, travelling expenses, and a small honorarium." The whole of the costs are met by the medical society and the State Department of Health, which has borne most of the cost of the lectures on obstetrics and pediatrics. The lectures are given on the same day for six or more successive weeks in the spring and autumn, and occupy one to two hours. No attempt is made to train specialists; the object is to raise the standard of practice in the community. The medical society believes that the majority of disease conditions yield to clinical diagnosis, which is still the most important factor in the practice of medicine. Consequently comprehensive laboratory courses are not included in the schedule. Alliance with medical schools and county medical societies is sought, and the plan is considered possible wherever there are hospitals and men willing and able to teach. The success of the scheme has been shown by the excellence of the attendance; in some instances men have driven sixty miles to the lectures. The altruism of the Medical Society of the State of New York, and of the teachers who accept emoluments consisting mainly of gratitude, is worthy of note. In propositions for post-graduate education it has usually been assumed that the general practitioner will be ready to sacrifice, not only time, but money, in the attempt to improve his knowledge of disease. From the practical point of making a livelihood it is possible that the average practitioner may be doubtful whether the sacrifice is worth making, especially in view of the educational facilities offered by medical journals and by meetings of medical societies. Although it is generally held that what is worth having is worth paying for, yet the gentle art of advertisement teaches us that free distribution of a commodity may do much to popularize its use. Under skilful and enthusiastic organizers much might be done to redeem post-graduate education from failure. The experiment of the Medical Society of the State of New York in bringing free continuous education to the door of the general practitioner will be watched with interest.

INTERTRACTION.

A POPULAR remedy for boils is to "draw" them by applying a soap-and-sugar plaster; a copious welling-up of lymph from the subjacent tissues follows the application. Pondering over this phenomenon, Sir Almroth Wright surmised that "drawing" was possibly a not inappropriate designation for the process involved, and that the constituents of the plaster might actually exert traction on the lymph; he discovered that a solution of salt was as good a "drawing agent" as soap-and-sugar plaster, and thereupon instituted experiments on the intermingling of fluids, culminating in the practical application of hypertonic salt solution in the treatment of wounds, with which every surgeon is now familiar. Apart from this utilitarian result, there remained the theoretical problem of isolating and examining the supposed force of traction—or rather intertraction, since it seemed that the action must necessarily be reciprocal between the two fluids concerned. To the solution of this problem Sir Almroth addressed himself, planning a series of experiments of great simplicity and beauty, the descriptions of which will be found in the *Proceedings of the Royal Society*, B, vol. 92 (1921), and A, vols. 112 (1926) and 114 (1927). The thesis submitted to the test of experiment was that in the intermingling of a solution of salt with an albuminous solution of lower specific gravity, or with water, there comes into play, in addition to the forces of gravitation and diffusion, a third force *sui generis*—namely, "intertraction." The following experiment was regarded by Sir Almroth Wright as proving the existence of this force, and also its independence of gravitation. Two vessels, one containing strong salt solution and the other water, were connected by a syphon tube threaded with wick, the end of the tube dipping into the salt solution being closed with a tight cotton-wool plug. It was found that the water slowly passed into the salt solution, showing that the salt, provided that it were even lightly confined, exerted traction, and exerted it against the opposition of gravity. When an albuminous fluid was used instead of water, a more rapid and voluminous indraught of fluid into the salt occurred. Having thus shown that intertraction could not be explained as being merely a form of gravitation, it remained to show that it also differed essentially from diffusion, the only other physical force which effects the mingling of fluids. It was shown, by an experiment to be described, that intertraction is manifested in a manner totally different from that exhibited by diffusion. In diffusion the commingling is intermolecular and diffuse; in intertraction it takes the form of innumerable filiform fluid streams, which pass in both directions across the frontier of the contiguous liquids, can be rendered visible by suitable means, and have been compared by Sir Almroth to pseudopodia. A plug of cotton-wool soaked in an albuminous fluid stained with eosin was placed midway in a test tube; the lower compartment was filled, through a lateral opening, with a heavier saline solution, and the upper compartment with water. A rapid advance of coloured pseudopodia into the saline solution occurred, while the superjacent water above the plug remained free. In a companion experiment the salt solution was coloured instead of the plug, and in this case pseudopodia were seen advancing upwards from the surface of the former. Sir Almroth considered that diffusion could furnish no explanation either of the pseudopodial character or of the rapidity of the movement of inter-

penetration in these experiments, and that, as has been said, it was necessary to postulate a third force—intertraction—to explain the facts. Objection has been taken to this interpretation on the ground that at the moment of intermingling there may occur an interchange of salt and water between the two fluids, and that this would cause local changes in density, and thus, under the influence of gravity, initiate vertical currents such as would produce an appearance of pseudopodia. An experiment was therefore devised in which the production of these currents would be excluded. Three or four discs of filter paper infiltrated with an albuminous fluid coloured with aniline were placed one upon another between two glass slides, which were firmly clamped together and then immersed in a vessel containing saline solution of higher specific gravity than the albuminous fluid. By this arrangement vertical currents were excluded, but none the less coloured streamers radiated out horizontally from the edge of the discs. The above experiments, with many others of an analogous kind, are put forward by Sir Almroth Wright as demonstrating the operations of intertraction, and they furnish, in his judgement, conclusive proof of the existence of such a *vis operans*.

EDINBURGH ANNUAL MEETING: HONORARY DEGREES.

On the occasion of the Annual Meeting in Edinburgh of the British Medical Association the University will confer the honorary degree of LL.D. upon the following distinguished members of the medical profession: Lord Dawson of Penn; Professor Archibald Donald (Manchester); Dr. Charles E. Douglas (Cupar); Sir *William Hale-White*; Mr. Robert G. Hogarth (Nottingham), President of the British Medical Association; Dr. William Hunter; Professor T. H. Milroy (Belfast); Sir Berkeley Moynihan (Leeds), President of the Royal College of Surgeons of England; Sir John Herbert Parsons; Sir Humphry Rolleston (Cambridge); Dr. George Frederick Still; Mr. Wilfred Trotter; Sir Almroth Wright; Professor Vittorio Ascoli (Rome); Professor Jules Bordet (Brussels); Professor Harvey Cushing (Harvard University); Professor Charles L. Dana (Cornell University); Professor Knud Faber (Copenhagen); Professor Jan van der Hoeve (Leyden); Professor Otto Meyerhof (Berlin); Professor Otto Naegeli (Zürich); Emeritus Professor William S. Thayer (Johns Hopkins University); and Professor Théodore Tuffier (Paris). The ceremony will be held on Wednesday, July 20th, in the McEwan Hall.

LUNACY LAW AND ADMINISTRATION.

The Council of the British Medical Association, at its meeting on Wednesday last, had before it a draft report from its Committee on Lunacy and Mental Disorder dealing with the recommendations of the Royal Commission on Lunacy. The Council did not see its way to adopt the report in the form in which it was presented, and therefore did not come to an immediate decision. It instructed the committee to reconsider certain details of the report, and requested the chairman of the committee to circulate on its behalf the revised report to Representatives as a confidential document, in order that it may form the subject of a discussion at the Representative Meeting in Edinburgh next month. Among the references to the committee was an instruction to consider the situation that had arisen as the result of the findings of the jury in the case Harnett *v.* Fisher. The long-drawn legislation in this case was finally brought to an end by the decision of the House of Lords, fully reported in our issue last week (p. 1036). That decision turned wholly on a point of law, as is fully explained in an article published this week (p. 1084). We also printed last week a report of the finding of the jury at the rehearing of the case de Freville *v.* Dill, in which the jury found for the plaintiff, assessing damages at £50. The summing up of Mr. Justice McCardie, who heard the case, will have been read with particular interest by members of the medical profession. He observed that it was a serious matter that the Lunacy Acts contained no definition whatever of insanity, of unsoundness of mind, or of lunacy; they provided no test, set no standard, and gave no guidance in these matters. He added that a doctor called in to deal with an alleged lunatic was dealing with the most difficult subject known to the medical profession. Mr. Justice McCardie, having in mind the decision which was being delivered on the same day by the House of Lords in Harnett *v.* Fisher, deferred judgement. We understand that it will be delivered during the next sittings, which begin on June 14th.

PROFESSOR PAVLOV.

There will be found in this issue (p. 1070) a further and penultimate instalment of the series of articles entitled "A medical review of Soviet Russia" which Dr. Horsley Gantt has been contributing to our columns; this instalment deals with some of the recent work of Professor Pavlov, and we regret to learn that that distinguished physiologist has since last February been confined to his home. For over a year he has suffered from fever and indigestion, and a diagnosis of cholelithiasis was made. Professor Pavlov was submitted to operation under chloroform on May 27th. A stone was found and removed, and drainage inserted. Everyone will join with us in wishing him a speedy recovery. In April last he told Dr. Gantt that the two chief objects he now had in mind were to write his autobiography, embodying his general views of life, and his impressions of recent events; "these," he wrote, "I have viewed not from beneath, but from above, as I was not crushed by them."

The Duke of Connaught will distribute the prizes at St. Thomas's Hospital on June 21st at 3 p.m. On his arrival at the hospital His Royal Highness will unveil a tablet on which are inscribed the names of those of St. Thomas's Hospital who fell in the great war.

The Annual Oration before the Medical Society of London will be given on Monday next, June 13th, by Professor Harvey Cushing, M.D., F.R.C.S., of Harvard University, whose subject is the surgical aspects of acromegaly. The guests will be received by the President, Sir Humphry Rolleston, Bt., at 8.30 p.m., at the society's house in Chandos Street. The oration will follow at 9, and afterwards there will be a conversazione.

In connexion with the celebration at Guy's Hospital on July 8th of the centenary of the discovery of Bright's disease by Dr. Richard Bright, the Royal College of Physicians of London, of which he was a Fellow, will give a conversazione in the evening.

On the occasion of the ceremony at the University of Sydney, when the honorary degree of LL.D. was conferred on the Duke of York, a portrait was unveiled in the Great Hall of the University of Sir Alexander MacCormick, for many years lecturer in surgery at the University of Sydney.

A MEDICAL REVIEW OF SOVIET RUSSIA.

VI.—WORK OF PAVLOV AND OTHER SCIENTISTS.*

BY

W. HORSLEY GANTT, B.Sc., M.D.VIRGINIA.

(Formerly Chief of the Medical Division of the American Relief Administration, Leningrad Unit.)

PART I.—PAVLOV.

LITTLE is known in other countries—especially in England and America—of medical work in Russia. This is not only on account of the language difficulty, but because of the lack of intercourse with other nations, and of the small number of foreigners who enter the country to do research work. Even before the war few doctors visited Russia. During three years of my stay there (1922-23, 1925-27) I have known of no other foreigner from an English-speaking country doing medical work, and I met only one such visitor prior to the summer of 1926—Mr. T. R. Parsons, then of Cambridge, now of Montreal. During the summer of 1926, however, there were several British and American doctors travelling through Russia (Dr. C. P. Miller of the Rockefeller Institute and others).†

Because of this lack of information I shall give a sketch of some of the important medical work with which I have become personally acquainted, without attempting, of course, a comprehensive review. My excuse for presenting this miscellaneous and sketchy account is the fact that practically none of the material, to my knowledge, has been published in English, and parts of it have not yet appeared even in Russian.

First of all is the work of Pavlov. His researches in digestion have already been published in English.‡ His energies during the last twenty-five years, however, have been directed chiefly to the physiology of the brain. Since two of his books are to appear soon giving his own account of the achievements in this new field, I shall do little more here than call attention to these volumes.§

CONDITIONED REFLEXES IN THE DOG.

More than a quarter of a century ago Professor Pavlov began his observations on conditioned reflexes. During his work on the digestive glands he and other physiologists had observed a secretion of saliva which physiology could not explain—a secretion when the dog looked at food or even when it heard the footstep of the person who fed it. Secretion of saliva when the dog ate, or when artificially stimulated by an electric current, was explained by physiology as chemical or physical reflexes, but the secretion at the sight or thought of food was considered *beyond* physiology: it was called psychical.

However, Pavlov was not satisfied with so vague an explanation. He felt that this important fact, and other psychical ones, should be reduced to physiological and measurable terms.

For two years Pavlov could not decide whether or not to abandon the former psychological and (to him) barren explanation of the psychical flow and to launch out into a new and unexplored field of objective investigation.

"After deliberation on this subject, after a considerable struggle with myself, I decided finally, in regard to the so-called psychical phenomena, to remain in the role of a pure physiologist—an objective observer and experimenter, having to do exclusively with the external phenomena and their relations."

Professor Pavlov gives the following paragraph of definition of conditioned reflexes (*Conditioned Reflexes*).

"From the point of view of an objective observer all nervous activity of the dog . . . appears to us as reflex—that is, a reaction of the animal to the external world through the nervous system. We classify reflexes into two orders. The simple former 'reflex,' which we call unconditioned—this is a reaction in which an external phenomenon is united with a certain response of the organism by a constant and unalterable connexion. For example, every time a mechanical body impinges on the eye, there follows without fail a defensive movement. . . . From these old reflexes we distinguish a new series . . . where the union of the external phenomenon with the corresponding activity of the organism is of a temporary nature, is formed in the presence of certain conditions, continues in the presence of those or other conditions, and under certain other circumstances, can be later destroyed. Thus we differentiate between constant and temporary reflexes."

Afferent stimuli reaching the brain may produce either a motor or secretory effect. Pavlov used the latter and selected the salivary gland for several reasons: because of the ease with which its secretion can be collected, and because of its comparatively few nerve connexions with other centres. Although various animals may be used for conditioned reflexes Pavlov has chosen the dog.

The presence of food in the mouth of a dog produces a flow of saliva. This secretion is dependent upon a nervous connexion with which the dog was born: it is an unconditioned reflex. The sight of food also produces a secretion of saliva, but because it has, during the life of the individual dog, often been associated with the eating of food. This flow is a conditioned one—Pavlov's conditioned reflex. The *sight* of food is a *conditioned stimulus*.

But other stimuli than the sight of food may be made the signal for the eating of food—a bell, a light, a touch on the skin, an odour, etc. When these are used for the first time they have no specific effect, and are called *indifferent* stimuli.* They must be connected with the unconditioned stimulus (food) by a number of repetitions in which they precede the giving of food. After this they acquire the property of causing a flow of saliva of themselves—before the food is given. They are now positive conditioned stimuli. They are conditioned because they may lose their acquired property if they are not accompanied by the *unconditioned stimulus*—food.

Besides the *positive* conditioned stimulus and the indifferent stimulus, there is the *negative* conditioned stimulus. For example, suppose a metronome of 100 beats has been made a positive conditioned stimulus, then just after metronome 100 is put into motion the dog is fed, and this connexion is repeated, say, fifty to a hundred times, until the dog begins to secrete saliva when the metronome begins—before he gets or sees the food; then let another metronome of 50 beats a minute be started—the dog begins to secrete saliva because of its resemblance to the first metronome 100. But if this metronome 50 is often repeated without food, it produces less and less saliva with each repetition and becomes a negative conditioned stimulus. *Inhibition* is set up in the dog's brain which prevents a flow of saliva. Thus this agent has an action opposite to that of the positive conditioned stimulus.

In order to form conditioned reflexes the operator and the dog sit in adjoining but separate rooms. The dog does not see the experimenter, who gives the various stimuli by means of pneumatic devices on the outside of the dog's room, having (electrical or pneumatic) connexions through the walls. The food is given and removed automatically, and the flow of saliva is measured by sealing a glass "balloon," hermetically, over an artificial opening of the salivary duct from the parotid gland. This "balloon" has two glass tubes leading off from its sides. The lower one is closed except when the accumulated saliva is suctioned off. The upper tube communicates with a manometer in front of the operator on the outside of the dog's room. As every flow of saliva into the "balloon" increases the pressure, the fluid in the manometer is forced along a scale whose divisions correspond to 0.01 c.cm.

Professor Hanicke in Pavlov's laboratory has perfected an apparatus for recording electrically the flow of saliva on a smoked drum. The fluid in the manometer is an electrolyte; it is forced out so that each drop as it falls makes

---

* Section V of this series, entitled "The Medical Profession, Soviet Science, and Soviet Sanitation," was published in the JOURNALS of January 29th and February 5th, 1927, at pages 198 and 244 respectively.

† Among those I saw was a young American physiologist, who, having convinced himself of the importance of Pavlov's investigations, determined to see them at any cost; having waited all the summer for an entrance visa, he found it necessary to abandon his trip to the Stockholm conference, and had means to remain only ten days in Russia—his entire European sojourn—but with the satisfaction of having seen first hand the laboratory and methods for which he had sacrificed a summer and travelled 14,000 miles. The visitor returned to America penniless.

‡ I. P. Pavlov: *Work of the Digestive Glands*, Lippincott, 1910.

§ One of these, *Activity of the Cerebral Hemispheres*, Pavlov has written expressly for the English language, and, as he told me, to pay a debt of gratitude which he owes to England and to America for their help to his country during the famine. It is being translated by Dr. G. von Anrep, and will be published by the Oxford Press. The other, *Conditioned Reflexes*, is also in course of translation, and is to be edited by Dr. W. B. Cannon of Harvard.

* These stimuli, though indifferent for the food reaction, are not entirely without effect, for they call out, when first used and before they have a specific action, the focusing or investigating reflex.

an electrical contact between two electrodes. At the closing of this fluid switch the needle makes a mark on the drum. The needle moves on a horizontal thread parallel with the drum so that the record is continuous. Thus what the psychologist might term the thoughts of the dog on hearing a bell or seeing a light which has been associated with food or, in Pavlov's terminology, its reaction to a conditioned stimulus) is literally written down by a purely mechanical method, by a needle moved by electricity—a brain process of the animal transferred to paper, without the intervention of the experimenter—by an entirely objective method.

For many experiments with conditioned reflexes no special precaution is taken to isolate the dog from the operator and the outside world. For some experiments, however, in which very faint sounds, etc., are used, isolation of the dog is carried to a high degree. In Pavlov's new laboratory, which was begun before the war but is only just now completed, this isolation is accomplished in the following way. The whole building is surrounded by a trench filled with sawdust to dampen vibrations coming through the ground. In order to separate the experimental rooms as widely as possible, they are situated only on the four corners and on the first and third floors—none in the intervening story. Each experimental room has walls two feet thick, and double iron doors padded with rubber. This room, in which the operator sits, has ground-glass windows, so that his attention is not distracted by looking out of doors. The entrance into the dog's room or cabinet—another chamber within this experimental room—is through double or triple concrete doors, each one about four to six inches thick. They are padded with rubber and securely bolted during an experiment. The walls of the dog's cabinet consist of two or three concentric shells of concreto, each one four to six inches thick; they are separated by some porous material to prevent conduction of sound.

Every precaution is taken to eliminate adventitious sounds, which might spoil the whole investigation. For example, suppose the conditioned stimulus, the signal for feeding, is intended to be an optical one, a whirling figure. If the movement is accompanied by some noise, even too faint for the human ear to detect, the dog may react to the auditory component entirely, and the result obtained so that characteristic for ear stimuli and not for visual. This indicates the importance of mechanically perfect apparatus. The defect just referred to is now to be overcome by the projection of optical figures from the next room through a "port-hole" window on to a screen in front of the dog. All the apparatus used in Pavlov's work with conditioned reflexes has been devised with great ingenuity. Professor Hanicke, who has been with Pavlov for thirty-five years, and Dr. P. S. Kupalov, Pavlov's brilliant first assistant at the Institute of Experimental Medicine, have contributed much toward the perfection of the present apparatus and instrumentation.

The operator, sitting on the outside of the dog's cabinet, gives the desired stimulus (by pressing a rubber bulb, etc.), and he can see the animal through a periscope over a small glass window in the wall of the camera. Although the salivary reaction is mechanically recorded, it is sometimes necessary to observe the movement reaction, to see if the dog is sleeping, etc.

By his method of conditioned reflexes Pavlov thinks he has discovered the nature of sleep and of *neurasthenia*. Both of these he has produced artificially in his dogs, by giving them too difficult problems of differentiation. For example, suppose a tone of a certain pitch is made a positive conditioned stimulus, and another tone of a distinctly lower pitch is made a negative conditioned stimulus (that is, it is not accompanied by food), then let a third tone be taken so close in pitch to the first that the dog cannot distinguish between them; there results a lack of balance of the processes of stimulation and of inhibition, and the animal develops symptoms of neurasthenia, refusing to eat, whining, etc. Pavlov has cured such dogs by rest and bromides.

Not only has light been thrown on the processes of sleep and neurasthenia, but by means of this method work has been done on the localization of brain centres. For example, conditioned reflexes are formed from the eye, skin, etc., and after removing parts of the brain, the extent to which these conditioned reflexes are lost can be observed.

Pavlov believes that all acts are reflex. Thus he speaks of the *reflexes* of freedom of purpose in his book *Conditioned Reflexes*. In the first chapter of *Activity of the Cerebral Hemispheres*, he avers that there is no essential difference between reflexes and instincts. Such instincts as nesting he considers a chain of reflexes. He points out that we know of simple reflexes united in chains, where the end of one is the stimulus for the beginning of the next—for example, irritation of an afferent nerve gives an increase of blood pressure, the high blood pressure in the aorta irritates the ends of the nervus depressor cordis, which neutralizes the effect of the first reflex. He contends, further, that the other former distinctions between instincts and reflexes are only superficial.

Pavlov claims for his method that it is objective, in contradistinction to the methods of psychology, which try to discover the laws of the brain by subjective methods. He writes (*Conditioned Reflexes*):

"Physiology of the higher departments of the central nervous system cannot be otherwise than a study founded on a purely objective basis, and completely removed from the indefinite ideas of psychology. What interest, for example, for physiological analyses can come from the statement of authors that after extirpation of certain parts of the brain the animal becomes malicious, less intelligent, etc., when these characteristics appear very complicated, and themselves need an exact scientific analysis?"

A casual perusal of his books may give the impression that his materialistic methods and logic exclude idealism, art, religion, etc., but those who read more carefully will find that, in spite of his mechanistic theory of life, he does not belittle the existence of spiritual things. In *Conditioned Reflexes* (Chapter X) he says:

"I should like to anticipate what might be misunderstood in these statements concerning my views. I do not deny or gainsay anything which relates to the innermost and deepest strivings of the human spirit. I only defend and affirm the natural rights of scientific thought everywhere, and until the time when and where it is able to manifest its own strength."

Such exhortations as the following appear frequently (*Conditioned Reflexes*, Chapter XXVII):

"If every one of us will cherish this reflex [of purpose] within himself, as a precious part of his substance, if parents and instructors of all ranks would make their chief goal the strengthening and development of this reflex, if our society and state would provide ample opportunities for practice of this reflex, then we should become that which we ought to and can be, judging from many episodes of our historical life and a few strokes of our creative strength."

His high ideals and hope for the future of science are evident from the following paragraph, written at a time when famine and disease hung like a pall over his native land, and he himself was sorely distressed over happenings in his country.

"Gradually with the movement of our work forward, these [errors] appeared more rarely, and now I am deeply and irrevocably convinced that this path leads to the final triumph of the human mind over its uttermost and supreme problem—the knowledge of the mechanism and laws of human nature. Only hence may come a full, true, and permanent human happiness. Let the mind rise from victory to victory over surrounding nature, let it conquer for human life and activity, not only all the surface of the earth, but the waters beneath and the air above; of the earth to the other, let it annihilate space for the conveyance of its thoughts—yet the same human mind led by dark powers to wars and revolutions with their horrors, not calculating the material loss and inexpressible pain, reproduces bestial relations. Only science, the exact science about the human himself, and the most sincere approach to it from the side of Omnipotent Nature, will deliver him from his present gloom, and will purge him from his contemporary shame in the sphere of inter-human relations." (*Conditioned Reflexes*, Preface.)

I shall take the further liberty to mention Pavlov's private views on two important subjects—religion, and the freedom of the will—which I have from him in personal conversations. Pavlov has stated in his public lectures that religion is the highest of conditioned reflexes and the one that distinguishes man from the beasts. In addition, I have heard him say that he considers life without religion very hard, in fact almost impossible for the mass of humanity; that personally, though not religious by nature, he envies those who are; that he has the highest respect for religion; and that if the doctrines of religion are taken

in their broad sense and not too literally, there is no essential conflict between it and science.

Pavlov has told me that, in his opinion, there is not at the present time freedom of the will in the absolute sense, although those who are educated, have travelled, and so on, apparently have some freedom of choice; that there will be real freedom of the will only when we understand the physiology of the brain. He says:

"As long as man did not understand the laws of Nature she was a mystery to him and he was her slave, but he has gradually passed from the position of slave to lord, and in direct proportion to his knowledge of the laws of Nature. I consider it parallel with the brain. Until he understands its physiology he cannot be free." (Personal conversation, April, 1927.)

Pavlov was 55 when he began this work on the brain. Now, at the age of 77, he is still working daily at it. He directs the work of fifty collaborators in three different laboratories, and six days in the week he is present there himself from 10 a.m. to 6 p.m., coming and leaving with military punctuality, and when necessary walking through the snow and ice.

CONDITIONED REFLEXES IN OTHER ANIMALS.

Conditioned reflexes have been formed by Pavlov's pupils, not only in dogs, but in such diverse animals as fish, mice, puppies, monkeys, and children.* The following apparatus is used for work with fish. The fish is suspended by a light clamp over its back, in a tank of water enclosed in a cabinet. Inside this cabinet are red and green electric lights, a metronome, etc. The unconditioned reflex is the motor response to an electric current sent through the clamp. The conditioned stimulus may be a light, a metronome, etc. A red light may be used for a positive conditioned stimulus (given before the electric current), and a green light for a negative conditioned stimulus (followed by no current). After a large number of trials the fish jumps (conditioned reflex) when it sees the red light (conditioned stimulus), but not when it sees the green. The conditioned and unconditioned stimuli and reflexes are recorded on a drum on the outside of the cabinet where the operator sits. (Work of Frolov.)

Mice.

The apparatus for forming conditioned reflexes in mice is very ingenious; it was perfected by Professor Hanicke in 1925. When a given bell sounds, the mice run to a certain place to get food, and in going there they have to cross a platform attached to springs. When they step on this platform the act is registered on a revolving drum. A revision of the former work on inheritance of conditioned reflexes is being carried out with an entirely new apparatus. The mice now receive all their food (twenty times during each night) preceded by the bell. It is all done mechanically, so that the presence of the operator is not required. A clock arrangement makes twenty electrical contacts during the night (the natural time for the feeding of mice), rings the bell, and a few moments later opens a valve which allows grain to drop into a certain compartment of each cage. When the bell rings there is a general migration of the mice into the "dining room." The mice never get food without the bell. Males and females are kept in separate cages, so that the number of oncoming generations can be carefully regulated. When an experiment is made the mice are removed to a special cage where the results can be registered automatically.

Puppies.

The apparatus for forming conditioned reflexes in puppies is the same in principle as that for mice. A metronome (conditioned stimulus) is started, and the puppy runs from his box across a gangway to a table on which is a basin into which milk pours from a reservoir. The operator and the reservoir for the milk are concealed behind a screen. The running of the puppy to the basin is a conditioned reflex—motor instead of the secretory used in the grown dog. The motor reaction is used in the puppy instead of a secretory because of the difficulty of keeping the puppy quiet in harness. When the puppy steps on the gangway this response, together with the time of action, etc., of the conditioned stimulus, are recorded on a smoked drum.

These methods, while showing the wide adaptation which can be made of conditioned reflexes, lack the exactness of the salivary reflex used in dogs. It is by this latter method that Pavlov has worked out his physiology of the brain.*

Observations on Children.

The work of Krasnogorsky in the Children's Clinic of the Medical Institute (Filatov Hospital) deserves mention here. Krasnogorsky is one of Pavlov's older pupils, and Professor Pavlov confers with him frequently in his work. He published his first observations on conditioned reflexes in children in 1907.† He has twelve doctors working under him on the subject, and three well equipped rooms for conditioned reflexes in children, and has received money from the Soviet Government for three additional ones.‡

The method used for children is as follows: the child lies upon its back on a pallet on the table, with a rubber bulb fastened under its chin. His mouth is placed directly under the opening of a metal funnel, so that the operator by pressing a button may cause a piece of chocolate confection to drop through the funnel into the child's mouth. The operator sits in a closet in the room from which he may see the child, but the child cannot see him. A metronome, a light, or irritation of the skin by the pressure of the rubber bulb attached to the arm or leg may be used as a conditioned stimulus, controlled by the experimenter sitting in the closet. The child is given no directions whatever. After making the conditioned stimulus, the operator presses the button, which allows the confection to drop into the child's mouth. After a few trials the child comes to expect food when he sees the light or hears the metronome, and he opens his mouth (conditioned reflex). The opening of the mouth compresses the bulb under his chin, which is pneumatically recorded on a drum before the operator. The normal child lies perfectly still on the little pallet for an hour or more with no attention from the experimenter.

To this motor conditioned reflex of the child Krasnogorsky has now (in 1926) added the secretory, as in the dog. A suction cup (as also used by Lashley in America) is fitted over the natural opening of the parotid duct, and the secretion of saliva is measured and recorded automatically on the drum, together with the motor response. Krasnogorsky tells me that he has found that the secretory reaction is parallel to the motor, and that he believes he has attained the full elaboration of this method for children.

Negative and positive conditioned reflexes have been formed, and the work of Pavlov on the dog has been more or less duplicated by Krasnogorsky on the child. Children develop conditioned reflexes much more quickly than the dog—ten to twenty-five trials, compared to the dog's thirty to one hundred; children retain them much longer and more strongly than the dog without intervening practice; they can be destroyed more quickly in the child—for example, when a positive conditioned stimulus is repeated several times without being supported by food. (Dr. Krasnogorsky showed me such an experiment in which the positive conditioned reflex disappeared after twelve trials unsupported by food—that is to say, the child which had a conditioned reflex (opening its mouth) on hearing the metronome because it received food (unconditioned reflex), ceased to open its mouth when the metronome was sounded twelve times successively without food.) Differentiation for musical tones, and skin stimuli, and differentiation in general, are much more delicate in the dog. Trace reflexes are more easily developed in the child. Synthesis is much better in the child than in the dog.

* Other workers, as Bekterev, have applied conditioned or association reflexes to adults, using a motor response of the finger, word association, etc., but as this is outside the work of Pavlov's laboratory and seems to be nearer to psychology than to physiology, a description is omitted here.

* Fursikov, who worked with Pavlov for ten years at the Institute of Experimental Medicine, is now investigating (at the new Brain Institute in Moscow) conditioned reflexes in monkeys. An account of this and further details of conditioned reflexes, were given in *Archives of Psychology and Neurology*, April, 1927, by the writer of this article.

† Russky Vratch, No. 36907 (Russian).

‡ For bibliography see the excellent review by Kroll, *Jahresberichte des gesamte Neurologie*, 1922; N. I. Krasnogorsky, *Revue de Médecine*, 1923; N. Krasnogorsky, Der Schlaf und die Hemmung, *Monatsschr. f. Kinderheilk.*, Bd. 25, p. 372.

Krasnogorsky's observations were made on children aged from 1 to 5 years. He has found it impossible to develop conditioned reflexes in infants less than two weeks old. In children under 1 year the mechanical irritation of the skin is not specific. The skin analyser begins to function at about three months. At the age of 7 months the child differentiates between red and white light, at 8 months between odours of camphor and eau-de-Cologne. The movement analyser appears at 6 months of age.

Krasnogorsky has shown the clinical importance of conditioned reflexes in denoting the disturbance between the balance of inhibition and stimulation. His work gives a rational basis for classification and treatment of neuroses. He suggests its use also as the basis for child education. Krasnogorsky in 1925 found by his method of conditioned reflexes that an idiot child in his clinic had a brain on the level of a fish—that is, it was as slow as the fish in forming conditioned reflexes. In myxoedema, epilepsy, and neuroses, internal inhibition develops in the child. Children older than 1 year may form internal inhibition. It is quickly elaborated and slowly disappears with time, but disappears rapidly if the conditioned stimulus is unsupported by food. Imbeciles develop conditioned reflexes with difficulty, but some neurotic children develop them more quickly and lose them more quickly than a normal child. Leonov in Krasnogorsky's laboratory found in rachitic children that the movement, taste, and smell analyser is disturbed; orientation and adaptation are weak; motor reflexes are slowly formed, but when once present disappear slowly.*

Trophic Nerves.

There has been no additional work on trophic nerves from Pavlov's laboratory since the account that was given in the BRITISH MEDICAL JOURNAL for September 20th, 1924 (p. 535). However, I have had pointed out to me in his laboratory several cases of eczema-like eruptions and ulcers in dogs suffering from overwork and neurasthenia.

POOR LAW REFORM.

IT has been known for some time that the Minister of Health has been in communication with those members of Parliament who constitute the Unionist Agricultural Committee with regard to modification of his proposed scheme for the reform of the Poor Law so far as rural areas are affected thereby. Last week there appeared in the daily press an announcement of the "scheme which has been agreed upon by a subcommittee of that body and by representatives of the Ministry of Health." This announcement has all the appearance of an official or semi-official communiqué. Yet its wording is, in one respect at least, extraordinary. It is stated to have been arranged that the Minister of Health shall circulate the scheme to the associations representing local authorities "as a basis of discussion between him and the local authorities, subject to the financial details being eventually satisfactory to the committee." Since when has a sectional group of members of Parliament been granted a limiting or controlling voice with regard to negotiations between a Minister and those whom he thinks fit to consult, or as to the form in which the Cabinet or a Government department shall present its proposals to Parliament?

The "main heads of the scheme" are given in the announcement, and considering all that has happened with regard to the published provisional proposals of the Minister, which have now been under discussion for a long time, they are sufficiently startling. They go far beyond a mere modification of those proposals to meet the circumstances of rural areas; and, though the changes they are intended to effect are not always very easy to grasp clearly, they appear to constitute a complete new scheme, in substitution for the previous proposals, and to involve an almost entire abandonment of the principles on which those proposals were based and of almost all the advantages which they were calculated to produce. Under the new scheme boards of guardians are not to be abolished; their mode of election in urban areas is merely to be indirect instead of direct, while the position of a rural district councillor as *ex officio* a guardian is to be universally confirmed. There is to be an adjustment of Poor Law areas so that each county borough shall be such an area complete in itself (the town council becoming also the board of guardians), that no such area shall be partly in one administrative county and partly in another, and that agreed modifications may be made in the boundaries of such areas within a county. It may be assumed that some adjustment would actually be made in most counties. Apart from such adjustments, and the abandonment of the *ad hoc* election in urban areas, however, no change of any great practical importance appears any longer to be contemplated.

All Poor Law institutions (workhouses, hospitals, schools, cottage homes, etc.) would be transferred to the county council or county borough council. Thus a county borough council would be the Poor Law authority, owning all Poor Law institutions within its area. Outside county boroughs there will be, first, local boards of guardians administering the Poor Law generally from their own offices, but not owning any institutions, and secondly, the council of the administrative county, not administering the Poor Law at all as was originally intended, but merely owning all the Poor Law institutions and apportioning the cost of their maintenance among the boards of guardians who use them, and being compelled to provide accommodation in all kinds of institutions on the demand of any board of guardians. The separate boards of guardians who use the institutions are to pay according to user, so that in practice what obtains generally at the present time will not be altered. The institutions, though owned by the county, will be maintained by the boards of guardians, and even now most boards who have superfluous accommodation take in boarders. Some economy will probably be effected in some agricultural areas where at present many Poor Law institutions are filled to only a small proportion of their capacity and so are being maintained at an excessive cost. It is proposed that the councils of counties and of county boroughs shall have power (but not the obligation) "to make provision for co-option, where desirable, on boards of guardians or on committees as the case may be, of women members and of persons experienced in Poor Law work." The management (but, as explained above, not the financial support) of transferred institutions will be in the hands of a committee of the county council. In most areas this will be complicated, as there may have to be separate committees for each institution, for the local board of guardians in whose area an institution is situated, by whomsoever it may be used, is to be entitled to one-third of the representation on the committee of management of such institution. Thus, in this respect the workhouse or other Poor Law institution will differ from the county asylum. Provision is, of course, to be made for the transfer and superannuation of existing Poor Law officers in accordance with established precedents.

The chief merit of the previous provisional proposals was that they constituted a great step towards the unification of health administration in each area, and made some advance towards a corresponding unification of educational administration. It was on this ground that, with some reservation on a few important points of detail, the British Medical Association has given these proposals its strong support in general. It will be seen that, should the new scheme be adopted instead, this main reform would be almost wholly abandoned. It is true that in county boroughs the town council would be the board of guardians, but the scheme contains no provision for the distribution of transferred functions to their appropriate administrative departments—health services to the medical officers and public health committee, education services to the education officers and education committee, and so on. Outside county boroughs there would no longer be any pretence of such unification. There would be no provision for transferring to large non-county boroughs or urban districts

* For further description of conditioned reflexes in neurotic children, see Krasnogorsky: *Amer. Journ. Child. Dis.*, December, 1925.

those Poor Law services which are similar to, or even identical with, those which these authorities already provide and administer—maternity and child welfare work, education work, and the like. The number of separate authorities might be slightly diminished, but the overlapping and duplication of the work of the large number that would remain would probably be even more pronounced than before. On one point to which the Association attaches considerable importance—co-option—the new proposals would make the position even more unsatisfactory than it was under the old. There would be no power of co-option on to the health committees, but only on to the boards of guardians and on to the committees of management of institutions, and persons co-opted would not be such as are experienced in health services or administration, but, much more narrowly, those who had had such experience in Poor Law work merely. Moreover, in rural areas, that preponderance of power in the hands of the rural district councillors which in many areas has made Poor Law administration a dead letter or a scandal, would be confirmed and strengthened without any provision for appeal, substitution, or redress.

It is fair to state that some mitigation of the criticism on one of the above points may be found in the provision that the council of a county or county borough may make proposals for the partial use of a transferred institution "for other purposes in relation to its general health organization." Such a provision would in some cases enable some institutional accommodation to be used instead of remaining idle; but from the point of view of administration, in view of the other proposed arrangements for management and finance, this would complicate matters still further. It is to be presumed that the new scheme will be seriously discussed between Mr. Chamberlain and the representatives of local authorities. It might still be found possible in the case of county boroughs to preserve some of the best features of the old proposals in conjunction with the new; but it is difficult to see how, in other respects, the new scheme can be reconciled with the policy of the Association. Indeed, the danger is that, if carried into effect, it may be an actual obstruction to the success of that policy by producing an illusory appearance of something important having been done, whereas in essential matters things would in fact be very much as they were. If the long-promised bill for Poor Law reform is at last to be introduced early next year it seems desirable that the Council of the Association and the special committee dealing with this subject should seriously consider the new situation and make representations to the Minister of Health at an early date.

The main heads of the scheme, as they appeared in the *Times* of June 2nd, are as follows:

(1) On a day to be appointed by the Act the councils of county boroughs to become the guardians for those boroughs, and subject to what is hereafter provided, the councils of non-county boroughs and other county districts to become the guardians for such boroughs and county districts.

(2) As soon as possible after the passing of the Act, the councils of counties and county boroughs to make a survey of Poor Law institutional accommodation in consultation with existing Poor Law authorities and their officers. Where a county or county borough includes any Poor Law area which extends into another county or county borough, the survey, as far as it affects such area, to be made in consultation between the councils concerned.

(3) As soon as possible after the passing of the Act councils of counties in consultation with the councils of non-county boroughs and county districts should take into consideration the areas of existing Poor Law unions and should readjust them on the following principles:

(*a*) that the area of each county borough is to be a single union;

(*b*) that the area of each union is to be inside a single county;

(*c*) that the area of each union must coincide with the area of one or more non-county boroughs or county districts;

(*d*) that where it can be shown to be advantageous, having regard to such factors as the extent of pauperism, population and rateable value, convenient administrative centres and availability of offices, the number of unions in the county area may be reduced.

(4) The proposed new boundaries to be included in county council schemes to be submitted to the Minister, who would be empowered to approve, with or without modification, and himself to make a scheme in case of default. Provision to be made for proper publication of schemes and power to councils of non-county boroughs and county districts to make representations to the Minister in respect of any scheme.

(5) The board of guardians for each union thus constituted to be a body composed of the rural district councillors for each rural district comprised in the area, together with a proportion of the councillors of the non-county boroughs and urban districts comprised in it. Power in this case also for the non-county borough and county district councils to make representations to the Minister.

(6) On a day to be appointed by the Act all institutions (other than offices for general administration, offices of relieving officers and similar buildings) and liabilities in connexion therewith to be transferred to councils of counties and county boroughs respectively. If the area of the former Poor Law authority was wholly within a county borough or county the transfer to be to the council of the county borough or county concerned. Where the area of the former Poor Law authority was not wholly within one county or county borough the institutional property and liabilities to be transferred as may be agreed between the councils concerned, or in default of agreement the matter to be determined by order of the Minister. Any agreement or order to provide for transfer, with or without conditions, or for joint user, and so far as adjustment of institutional property and liabilities are concerned, to be subject to general rules.

As regards all other properties and liabilities:

(*a*) Where the area of the former Poor Law authority was comprised within a county borough or within the area of the Poor Law union constituted by the county council scheme properties and liabilities to be transferred to the council of the county borough or to the guardians of the new Poor Law union.

(*b*) Where the area of the former Poor Law authority was not comprised within the area of a county borough or of a new Poor Law union the transfer to be matter for agreement between the county boroughs or Poor Law unions concerned, subject to determination of the Minister in default of agreement and to provisions for adjustment where required.

Where a county or county borough or a new Poor Law area includes the whole or parts of two or more former Poor Law unions, equitable adjustments to be made in accordance with general rules contained in the Act, in respect of the institutional and other properties and liabilities of the several Poor Law authorities transferred to the council of the county or county borough or to the guardians of the Poor Law union constituted by the scheme, unless the authorities concerned (including the boards of guardians of the former unions) shall have agreed before the appointed day that an adjustment is unnecessary.

(7) As soon as possible after the passing of the Act, county boroughs to prepare and submit to the Minister for approval a scheme of administrative arrangements and use of institutions transferred to them as above, after consultation with county councils and councils of county boroughs as may be necessary having regard to present use made of Poor Law institutions.

(8) Counties and county boroughs to have power to make provision in their scheme for co-option where desirable on boards of guardians or on committees as the case may be of women members and of persons experienced in Poor Law work.

(9) County councils to prepare schemes for the use of institutions transferred to them after consultation with the new Poor Law guardians, and with the councils of such other counties and county boroughs as may be necessary.

(10) General power of authorities to form combinations amongst themselves.

(11) The expenses of the new guardians to be borne on the rates of the new unions.

(12) Subject to any arrangements of Parliament as to the allocation of the registration of births, deaths, and marriages, the new guardians to have the same powers and duties as the old, provided that they shall not be empowered to own or lease any institution or building (except their offices). The duty of providing accommodation for vagrants and for the purpose of work tests for the able-bodied to be placed on the county council or county borough.

(13) In cases where institutions are used by boards of guardians, the committee of management of each institution to be appointed as to not less than one-third by the new Poor Law Guardians in the area in which it is situated. The expense of running the transferred institutions and any new institutions required for Poor Law purposes shall, subject to provisions as to repayment, be a county or county borough charge, and the council of the county shall be under statutory obligation to make the required institutional provision for the needs of poor relief in their area and to take over cases on demand from the guardians. Except as regards institutions provided for vagrants and persons undergoing work-test, repayment shall be made to the county council by the guardians for each class of case on such terms, not exceeding the cost of maintenance, as may be agreed or determined by the Minister in default of agreement. (The cost involved in such repayment being a charge on the union area.) For the purpose of enabling them to carry out the obligations imposed upon them the county council shall have power to make arrangements with the councils of other counties, county boroughs, boroughs, or other county districts for the reception of cases of infectious diseases, maternity and child welfare and education coming under the Poor Law.

(14) Each county and county borough council to include in its scheme dealing with institutions proposals for the use of the transferred institutions for the above purposes and for other purposes in relation to its general health organization. Power for a county or county borough council to take cases from outside its area on agreed terms.

(15) Provision for transfer, superannuation, etc., of existing Poor Law officers in accordance with the established precedents.

THE PERMANENT USE OF THE TRACHEOTOMY TUBE.

SIR STCLAIR THOMSON'S ADDRESS.

SIR STCLAIR THOMSON delivered an address on the permanent use of the tracheotomy tube before the Interstate Post-Graduate Assembly of North America on June 3rd. He referred to the anxiety exhibited by many surgeons to dispense with the use of the cannula as soon as possible after tracheotomy had been performed and its more immediate objects attained; the main object of his address was to demonstrate that the practice was unreasonable and unwarrantable, and that the permanent use of the cannula was not only harmless but of great advantage to the patient in suitable cases.

The objections which had been raised to the permanent use of the cannula were various, the chief being that in the unnatural mode of respiration which it involved the inspired air was not warmed, moistened, and filtered as in the natural process, and consequently the lower air-passages were rendered liable to bronchial, pulmonary, and other troubles. Other objections were that speech was interfered with, and that the tube caused local discomfort and social disability. With regard to the normal mode of respiration, Sir StClair Thomson fully recognized its importance, and had himself shown, by researches on the defensive mechanisms of the nose, that under normal conditions inspired air in its passage through the nose becomes warmed, saturated with moisture, and sterilized before it reaches the lungs or even the larynx. Nasal respiration, however, was not always possible as a permanent mode of breathing. In children, in whom it was of particular importance, it was, fortunately, possible, by attention to adenoids, tonsillar affections, and other conditions, to retain or restore it before secondary effects on the developing body resulted from obstruction of the passages. In the adult, the absence of an adequate nasal airway was by no means as important as in children, although the onset of nasal stenosis and consequent mouth-breathing certainly reduced the protection afforded by the nasal cavities. Symptoms in the adult, attributed to nasal lesions, were, however, often due less to stenosis than to the accompanying sepsis. The permanent use of the tracheotomy tube in children, Sir StClair Thomson admitted, was liable to be followed by serious consequences. In them there was a greater tendency to respiratory catarrh, and the unused nasal and pharyngeal cavities failed to develop fully and the larynx to expand; education was handicapped by defective speech, and the inability to mix freely with playmates was a serious hindrance to general development. In the adult, on the other hand, many of these drawbacks were absent. Neither in the matter of growth nor education could any ill effects arise; defects in the voice would be referable, not to the cannula, but to laryngeal or other lesions; and local discomfort in the neck, due to pain, discharge, the necessity for changing dressings, and the frequent cleansing of the tube, was entirely absent in well planned tracheotomies. Social disability hardly existed, and the "canulard," as the wearer of a permanent cannula was called by the French, was in no way precluded from engaging in social functions, games, and physical exercises, with the exception of swimming. That a tracheotomy tube could be worn without inconvenience for prolonged periods was attested by cases such as that of a healthy old lady of 81, who had never suffered from bronchitis, although she had worn a cannula for seventy years, and a patient who died of senile decay at the age of 81, after wearing a tube for over fifty years.

It was probable that cases such as these would be more frequently met with if certain detailed precautions were observed in the performance of tracheotomies. In many cases the tube was introduced through the first ring of the trachea and the cricoid cartilage, through the cricoid and the crico-thyroid membrane, or even through the latter and part of the thyroid cartilage. As a consequence there was much catarrh and irritation of the larynx, the soft structures in the subglottic region became infected, perichondritis was a not unlikely complication and septic bronchitis a frequent sequel. Further, ill considered operative measures to dilate a stenosed larynx with a view to cure a "canulard" not infrequently resulted in death. In cases where, after a tracheotomy, it was proposed that the tube should be worn permanently, the operation ought to be performed as low as possible in the neck and always below the three first rings. In this situation, with the opening in the trachea immediately above the upper margin of the sternum, a cannula was easily concealed, did not interfere with the movements of the neck or larynx, caused no damage or irritation, and never set up perichondritis. In cases where a high tracheotomy had, as a matter of urgency, been performed and there was a probability that the tube would have to be worn indefinitely, there was no reason why a second tracheotomy should not be performed lower down in the neck and the higher opening be allowed to close.

In many instances the laryngeal condition calling for tracheotomy could be removed, or a resulting stenosis of the glottis cured; in such cases the tracheotomy tube could be abandoned with safety. This was possible in such conditions as impacted foreign bodies, acute laryngitis, oedema of the larynx, diphtheria, typhoid ulceration, syphilis, and tubercle. On the other hand, there were many cases in which a laryngeal stenosis was permanent, and it was to the principles of treatment to be recommended in such cases that Sir StClair Thomson particularly desired to call attention. In the first place an attempt to cure the stenosis itself was liable to fail and entail further damage or complete loss of voice; or, again, surgical intervention might merely scar the neck, stimulate to further stenosis, or encourage recurrence of arrested disease. Moreover, many of the methods employed for overcoming a laryngeal stenosis were tedious, painful, often unsatisfactory, and not free from danger. In the second place the permanent wearing of a cannula in a well executed opening just above the sternum was, in adults, by no means the disaster it was often represented to be; and it was not incompatible with a long, healthy, and useful life. In the third place the wearing of a tracheotomy tube would in many cases preserve a useful voice, while avoiding the alternative of a mutilating excision of the larynx.

Sir StClair Thomson exhibited some permanent "canulards," including cases of complete bilateral laryngeal paralysis, lupus, stenosis from surgical trauma, syphilis, tuberculosis, enchondroma, and carcinoma. The following are brief notes of some typical cases:

A woman, aged 20, with a goitre and marked stridor from complete bilateral abductor paralysis; has worn a tube for four years, without a day's illness or any respiratory trouble; voice good; tube easily concealed and causing no disability.

A man, aged 47; a year previously a carcinoma of the right cord was removed by thermo-cautery and a tube worn for six months; the larynx closed almost completely; laryngostomy and dilatation with rubber tubes during four months; glottis reduced to chink by cicatrization; low tracheotomy; patient greatly relieved, able to resume physical exercises, and voice improved; tube worn for seven years.

A woman, aged 34, with stridor and suffocative attacks from syphilitic stenosis; two years' treatment unavailing; low tracheotomy; in robust health twenty years later; able to take physical exercises; never subject to bronchitis.

A woman, aged 33, with urgent stenosis from lupus, which had been treated since the age of 5 years; low tracheotomy; tube now worn for eleven years; able to take physical exercises; voice strong and clear; experiences no social disability; tube readily concealed; never has bronchitis.

A woman, aged 42; dyspnoea on the slightest exertion, resulting from cicatricial contraction of the glottis following cure of a tuberculous deposit by means of the galvano-cautery; low tracheotomy; tube now worn for three years; in active work and able to walk several miles; voice good.

A woman, aged 32; tuberculous deposit cured by galvano-cautery, but followed by gradual stenosis necessitating tracheotomy after five years; low tracheotomy; in active work and can walk for miles; tube now worn for five years without inconvenience.

A man, aged 29; laryngeal stridor for eighteen months due to fungating tuberculous deposit obstructing glottis; low tracheotomy; ten months later he was free from stridor, the glottis was free and the fungating deposit had disappeared; could only speak in a whisper.

A woman, aged 41; carcinoma involving entire right vocal cords; removal by laryngo-fissure; recurrence; right half of thyroid and cricoid excised through lateral pharyngotomy, and skin-flaps folded in to make fresh lining to larynx; lumen of larynx insufficient; has worn low tracheotomy tube for seven years; voice strong;

is in active work and able to walk long distances; never has bronchitis.

A woman, aged 57; carcinoma of the right cord had been removed seven years previously; recurrence in left cord; removal by laryngo-fissure, and low tracheotomy tube worn since (four years); laryngeal airway adequate for respiration, but not for active life she leads; speaks in low whisper; has never had bronchitis.

The last two cases illustrated very forcibly the advantages of low tracheotomy and the permanent cannula; the alternative would have been total excision of the larynx.

THE NEW SCIENCE SCHOOL AT CLIFTON COLLEGE.

OPENING BY THE PRINCE OF WALES.

WHEN Clifton College was founded in 1862 it was intended that it should rank as one of the "public schools." None of the others included natural science in their curriculum; but Percival, the twenty-eight-year-old headmaster of the new school, determined with singular foresight and courage to give it an important place and to secure the best teachers. The first appointment, that of Mr. (afterwards Professor) Leipner, was made in September, 1862. Percival introduced in the next few years a series of distinguished scientific teachers: Debus, afterwards professor at the Royal Naval College, Greenwich, and no fewer than five men who became Fellows of the Royal Society—A. W. Reinold, John Perry, Sir William Tilden, A. M. Worthington, and W. A. Shenstone—together with M. J. Barrington Ward and G. H. Wollaston. It was in the school laboratory that Shenstone first melted silica, and some of the early tubes and thermometers which he made are still preserved.

In 1867 Dr. Percival was able to open the first school laboratories in the kingdom, so that at a time when most schools made no provision whatever for science, Clifton had ample and well equipped laboratories, directed by a staff of brilliant scientists. The school rapidly gained a reputation for sound scientific education, and exerted a profound influence on contemporary progress. Its example has played a weighty part in securing the inclusion of science in the curriculum of our public and secondary schools.

While Clifton's reputation in the teaching of natural science has been maintained, the accommodation has for many years been out of date and inadequate. The erection of new and extensive buildings was a necessity if the school intended to hold its traditional lead in science. The council at length resolved to build an entirely new science school, so conceived and equipped as to place Clifton once more ahead of friendly rivals.

The Speaker of the House of Commons, the Right Hon. J. H. Whitley, M.P., an old Cliftonian, undertook to raise the necessary sum of £50,000, and has already obtained more than four-fifths of that amount from old members of the school. The services of an acknowledged leader in this style of architecture, Mr. Alan E. Muntz, were fortunately available, and the council empowered him to meet all the wishes of the science staff as to general arrangement, accommodation, and equipment.

The outcome of this far-sighted policy has been that the new science school, opened on June 2nd by H.R.H. the Prince of Wales, represents a great advance upon any other school science buildings in the kingdom.

The present design was arrived at after the consideration and rejection of several others. The preservation of the close for games was regarded as essential, and this accounts for the somewhat recessed position of the buildings, which cover a considerable ground area and are in Gothic style. Few modern science buildings are Gothic in design, but in this instance it was felt that the architectural surroundings of the college left no possible alternative, and by the adoption of a late period in this style the difficulty of securing the ample natural light necessary has been met satisfactorily. Bath stone has been employed, with local stone for general walling, as used in other college buildings.

The design comprises two principal floors with a partial basement and partial second story. The extreme length of the building is some 160 feet, and the breadth about 64 feet. It consists of a central block, which contains the laboratories and their adjuncts, with two wings of two stories only, devoted to four lecture rooms. The ground floor is devoted to physics, and comprises two elementary laboratories on the frontage (40 feet by 32 feet) on either side of the central entrance, giving access to a corridor, at the ends of which are the two lecture rooms with preparation rooms attached, approached also by separate external doors to the corridor terminations. On the other side of the corridor are: on the right, an advanced laboratory (37 by 20 feet) with adjoining store; and, on the left of the central staircase and goods entrance, a repair workshop and a masters' room (17 feet and 19 feet by 20 feet respectively). A small research room and dark room are also provided on this floor.

The first floor, devoted to chemistry, is similarly arranged, but provides between the large elementary laboratories a balance room and dispensary, and over the workshop is a biological laboratory. By reducing the corridor height on this floor some cross lighting and ventilation has been made possible in these rooms. A second floor is provided over the frontage rooms in the pitched roof, and is devoted to the science library, 40 feet by 22 feet, which is fitted in oak, and a geography room of similar size. The remainder of the building at this level provides an asphalt flat available for experimental purposes, and at a height which regards the admission of sunlight to the open swimming bath behind them. A basement, below the rear central rooms only, contains an accelerated hot water heating plant, steam plant for laboratory purposes, unpacking room, switchboards and batteries, and a hand lift connecting this with other floors. Water is available at two pressures; electric power is supplied both from mains and for low voltage work from batteries, and an automatic exchange telephone system connecting all rooms has been installed.*

When the Prince of Wales arrived at Bristol he was met at the station by the Lord Mayor of Bristol, with whom he drove through the streets of the city, welcomed by the cheers of the crowds and by beflagged shops and houses. At the memorial gate of the college the Prince was received by the President of the college (Earl Haig), the chairman of the council (Sir Herbert Warren), and the headmaster (Mr. Norman Whatley). Within the gate, where the names of those who fell in the war are inscribed, the Prince laid laurel wreaths. The members of the college council and the two senior masters (Mr. E. J. Barff and Mr. C. H. St. L. Russell) were presented to His Royal Highness, who then lunched informally with the boys in School House. Afterwards he walked to the new science school, pausing at the South African war memorial to place a wreath.

Earl Haig and the Headmaster welcomed the Prince in short speeches, thanking him for the honour he was conferring on the school, and His Royal Highness replied in a happy and apt speech. It was, he said, a particularly appropriate task for him to perform, seeing that he at present occupied the presidential chair of the British Association. In this capacity he had made many new friends, and had found that the learned men of science, of whom he had perhaps been a little afraid, had introduced him to many fresh interests. He advised the boys to pay some attention to natural science, even though it might not be their professional study, for the older they grew the more science was going to matter, and even a slight knowledge of it would add to the interest of life.

The head of the school then presented to the Prince the key of the building, a copy of a French key of 1870, with which the Prince opened the doors of the new school, and, passing inside, inspected the interior. He then visited the armoury and the library, and informally opened the new squash rackets and fives courts in the New Field.

It was a day of hot sunshine with cool breezes.

* We are indebted to the school authorities for courteously supplying details of the new laboratories.

BIRTHDAY HONOURS.

THE honours list issued on the occasion of His Majesty's birthday included the names of the following members of the medical profession:

K.C.V.O.

EDWARD FARQUHAR BUZZARD, M.D., F.R.C.P., Physician Extraordinary to the King; Physician to St. Thomas's Hospital.

K.B.E. (Civil Division).

CHARLES PERCY BARLEE CLIBBE, M.R.C.S., L.R.C.P., F.A.C.S., Consulting Surgeon, Royal Prince Alfred Hospital, Sydney, in recognition of services to the Commonwealth of Australia.

Knighthood.

CHARLES JAMES MARTIN, C.M.G., D.Sc., LL.D., D.C.L., F.R.S., M.B., F.R.C.P., Director of the Lister Institute, London (formerly Chairman of the Science Committee of the British Medical Association).

LOUIS EDWARD BARNETT, C.M.G., M.B., C.M., F.R.C.S., Professor of Surgery, Otago University, Dominion of New Zealand; President of the Australasian Medical Congress held at Dunedin, 1927, under the auspices of the British Medical Association.

C.B. (Military Division).

Major-General JOHN MACFARLANE SLOAN, C.M.G., D.S.O., M.B., late R.A.M.C., Deputy Director of Medical Services, Southern Command, India.

C.B. (Civil Division).

Colonel CHARLES PYE OLIVER, C.M.G., T.D., M.D., late Territorial Army.

C.V.O.

HENRY LINNINGTON MARTYN, M.V.O., M.B., F.R.C.S., Surgeon Apothecary to H.M. Household at Windsor.

C.I.E.

Lieut.-Colonel JOHN CYRIL HOLDICH LEICESTER, I.M.S., lately Officiating Surgeon-General to the Government of Bengal.

Major ALFRED GEDDES TRESIDDER, I.M.S., Surgeon to His Excellency the Governor of Bombay.

C.B.E. (Military Division).

Surgeon Captain ALFRED JAMES HEWITT, R.N.

C.B.E. (Civil Division).

NEIL MORRISON MACFARLANE, M.D., C.M., Principal Medical Officer, Basutoland.

WILLIAM MARSHALL PHILIP, M.B., C.M., lately Medical Officer of Health, Colombo Municipal Council, Ceylon.

O.B.E. (Military Division).

Surgeon Commander GUY LESLIE BUCKERIDGE, R.N.

Major CHARLES MORGAN FINNY, M.B., F.R.C.S., R.A.M.C.

Major JOHN HEATLEY SPENCER, M.D., R.A.M.C.

Captain HAROLD WILLIAMSON, M.B., F.R.C.S., I.M.S.

O.B.E. (Civil Division).

Dr. EDMUND LLOYD, M.B.E., Church Missionary Society.

Captain MAHOMED FAZAL-UD-DIN, I.M.S., Agency Surgeon at Jandola, South Waziristan.

ATTILIO CRITIEN, M.B.E., M.D., Chief Government Medical Officer and Superintendent of Public Health, Malta.

Mrs. CHARLOTTE ELIZABETH FERGUSON DAVIE, M.D., in recognition of her services in the Straits Settlements.

JOHN RANDALL PHILLIPS, M.B., Senior Member of the Legislative Council of Barbados.

Major HASAN SUHRAWARDY, Indian Territorial Medical Corps, medical practitioner, Bengal.

M.B.E. (Military Division).

Subassistant Surgeon Subadar GURDITT SINGH, I.M.D.

Quartermaster and Lieutenant JOSEPH EDWARD PUGH, R.A.M.C.

Jemadar SAYED GUL AKBER SHAH, Subassistant Surgeon, 2nd Cavalry Regiment, Iraq Levies.

Assistant Surgeon (2nd Class) HENRY CARLYLE WILLIAM WINDSOR, I.M.D.

M.B.E. (Civil Division).

KOBAD DHUNJIBHAI MUGASETH, Medical Practitioner, Calicut, Madras.

Kaisar-i-Hind Medal (First Class) (for Public Services in India).

Miss ETHEL ADELAIDE DOUGLAS, M.B., B.S., Medical Officer in Charge of the Kinnaird Women's Hospital, Lucknow.

Dr. CARL FREDRIK KUGELBERG, Church of Sweden Mission, Tirupattur, Ramnad District, Madras.

The Rev. CALEB DAVIES, Medical Superintendent, Santhal Mission Hospital, Sarenga, Bankura, Bengal.

Union of South Africa.

[FROM OUR CORRESPONDENT IN PRETORIA.]

ENZOÖTIC RABIES.

ALTHOUGH several outbreaks of rabies, more or less serious, were described as having occurred in South Africa last century, the disease has been almost entirely unknown in the Union during the past thirty years. There has been nothing comparable to the post-war prevalence which occurred on the continent of Europe. Of late years, however, disquieting evidence has emerged of the existence of rabies among two species of wild animals of the Union—the yellow mongoose and the genet cat. Both are small carnivores, the former belonging to the Viverridae and the latter to the Felinae. Both are shy animals, normally never approaching homesteads. But according to reliable native evidence they periodically go mad, and will then approach human habitations and actually attack persons. These natives maintain that a person or animal so bitten will often within a period of a month or two die after having shown signs of madness.

Since 1916 six cases have been described by country practitioners with symptoms indistinguishable from those of rabies, where the biting animal was shown to have been a mongoose. These cases have invariably been fatal after an illness never lasting longer than six days; in all it was found on subsequent inquiry that the patient had been bitten a month or six weeks previously by a mongoose. Unfortunately in none was pathological confirmation possible, as *post-mortem* material, when forwarded, invariably arrived at the laboratory in a decomposed state, so that neither recognition of Negri bodies nor inoculation tests were possible.

In December, 1920, a European male child on a farm in the northern Free State died two days after symptoms of rabies had appeared; six weeks previously he had been bitten in the shoulder while interfering in a fight between his domestic cat and a mongoose. The cat survived until after the death of the child, when it was killed and the head sent to the South African Institute for Medical Research in [illegible] result of the examination was negative [illegible] a case was reported from a farm in the [illegible] of the Transvaal. Eight weeks previous to the onset of symptoms the patient, an agricultural student, aged 21 years, had given chase to a yellow mongoose which he had come across wandering aimlessly on the veld. Ordinarily this creature is very active, and quite impossible to catch by chasing; yet this specimen was caught after being followed by its captor through four well strung barbed wire fences. It was, therefore, certainly not in normal health. When caught it bit the man savagely in the finger, and held on so pertinaciously that a knife had to be used as a lever to open the jaws. The case was described by the attending practitioner in the *South African Medical Record*, and the careful account left little doubt that the case was one of rabies. The relatives would not consent to a *post-mortem* examination, and the practitioner was unaware that such an examination could be ordered by the magistrate under Section 34 of the South African Public Health Act. The Department of Public Health was notified too late for confirmation by *post-mortem* and laboratory examination to be possible.

Last June a case was reported from a farm in the Wolmaransstad district of the Transvaal. A European boy, aged 7, was bitten by a yellow mongoose in the right hand, between the thumb and the first finger. He had found the animal lying ill in a prospector's hole. On lifting it, it took such a firm hold of the boy's hand with its teeth that his companions had to hit the animal with stones to induce it to let go. The wound healed cleanly, but some six weeks later the boy became drowsy and the site of the bite painful. Typical symptoms developed; spasm of the throat muscles of increasing violence occurred on attempting to drink; by the morning of the third day the lad was quite unable to swallow anything; the mere mention of fluid would bring on a violent spasm. Death occurred on the

evening of the third day, and the body was buried without examination.

In these and similar cases amongst natives, the infecting animal appears almost certainly to have been the yellow mongoose, locally known to the Boer farmers as the "witpuntstert meerkat" (*Cynictis penicillata*). We were becoming used to these cases when, last September, another animal became incriminated. A female European child in the Vryburg district of northern Cape Province became ill and died four and a half weeks after being bitten by a spotted genet cat. The symptoms described by the attending physician were again those of rabies. Thirty-two days prior to the onset of symptoms the parents had been visiting with the child at a neighbouring farm. All three slept outside on the stoep, the child being in a cot alongside the mother. The father was lying in bed smoking when he became aware of a noise in the cot. The mother woke, and, feeling instinctively with her hand for the child, encountered something furry, which she took to be the domestic cat. Trying to push this away she was bitten in the finger. Her husband then jumped up, and found that a wild cat had its teeth embedded in the child's throat. Removing the animal with difficulty, he was bitten in both hands. The cat was killed and thrown into the bush. After the child's condition (three and a half weeks later) had been diagnosed the parents were given a full course of treatment with carbolized antirabic vaccine, and neither developed symptoms. A *post-mortem* examination of the child was not performed.

Immediately this case was reported to the Department of Public Health an inquiry was instituted, and although no material suitable for laboratory examination was obtained some remarkable information was gleaned. In this and the neighbouring district of Mafeking there was found to be a general belief amongst both natives and European farmers that a fatal madness follows bites by mad wild cats. Only when mad will the genet attack man or large domestic animals, and then a fatal result is to be expected. An ox belonging to a progressive English farmer went mad and died some weeks after being bitten by a wild cat. Several natives and dogs were said to have died after similar experiences. There is little doubt that in the Mafeking and Vryburg districts rabies is endemic among the genets. They are handsome animals, and it is unfortunate that their extermination will become almost a necessity.

In addition to the cases directly attributed to mongoose or genet bites, several cases have been described since 1924 where the biting animal has been the domestic dog. But all these have occurred in regions where the yellow mongoose is plentiful, and the probabilities are that these dogs became infective through attacking or being attacked by diseased mongoose. Three cases of this nature have been reported since the beginning of the present year.

Hookworm in the Witwatersrand Mines.

Many causes have been assigned for the existence of the class of "poor whites" in South Africa. The occurrence of a certain number of poor whites in an essentially black man's country appears to be inevitable where it is insisted that the lowest white standard of living shall be considerably above that of the black standard. This standard of living assumes on the part of all whites capacities for earning superior to those of natives; and some whites will always fall short of such earning capacities. But in the Union the number of poor whites is relatively excessive; climatic and other causes to explain this are continually being sought. Without doubt in the malarious regions of the Union malaria is accountable for much lowering of earning capacity. At various times it has been suggested, without any apparent evidence, that in the semi-tropical parts of the Union hookworm disease might be an important contributory cause of the chronic lack of vitality and general ill health which characterizes the agrarian white population of these parts. There is still no proof and indeed little evidence in favour of this.

Though it is unlikely in the extreme that hookworm is parasitic in the intestines of Europeans of the Union unconnected with the mines other than as an exceptional occurrence, it has recently been shown that the parasites are quite common in natives working on one of the Rand mines; and even some European miners have been found to be infected. Last year a zoologist (Dr. Sanground) interested himself in the intestinal parasites of native mine workers. He examined the faeces of forty-six native patients in the City Deep Hospital and found that twenty-two of them were infected with hookworm. Dr. Orenstein, superintendent of sanitation of the Rand Mines, Ltd., decided as the result of this discovery that a systematic investigation of the subject was necessary. This is now being conducted by Professor W. O. Fischer, who has already made extensive examinations of the faeces of natives admitted to the City Deep Central Native Hospital. Similar examinations are to made at other mines. A preliminary report has been published by Professor Fischer and Dr. Orenstein; from the observations made at City Deep it is evident that a considerable number of the natives recruited from the East Coast (Portuguese East Africa) are infected with the parasite, and that infection occurs also in British South African natives. That the prevalence of hookworm amongst mine natives came almost as a sudden discovery is not very surprising when one remembers the well established fact that African races, though heavily infected, often show no obvious clinical manifestations of the disease.

After this investigation amongst natives had commenced the Miners' Phthisis Medical Bureau discovered the parasite in a group of ten European miners who had presented themselves at the bureau for medical examination. This appears to be the only group of European miners on the Witwatersrand known to have clinical symptoms demonstrably due to hookworm infection. The discovery of this European group led to an investigation of possible soil infection on the mines. In the four mines that have already been investigated hookworm larvae have been found in all in the soil forming the floor of latrines or their immediate neighbourhood and near drinking water containers. On these mines the only practical prophylactic methods are those which aim at guarding the mine soil from pollution, and the mass treatment of infected natives. A large proportion of the native miners do not habitually wear boots. Then the boots worn by native and most European miners are permeable to the water and mud both because of disrepair and because the lace-up type is used which permits of the entry of water through the lace holes.

Native Medical Practice in the Union.

There are in practice in the Union of South Africa six African Bantu natives. All of them are fully qualified, and, being on the *Register*, have the full rights and privileges of medical practitioners. Some of them appear, on their own evidence, not only to have large practices among Europeans, but to have actually more European than native patients. In view of the pressing need for medical services in the native territories this tendency of native graduates to adhere to the towns and practise chiefly among Europeans has caused adverse comment. It would appear to be most uncertain that State money spent in assisting native students to qualify in medicine would tend to alleviate native suffering in the territories. Even if such graduates were under contract to serve in the kraals, experience in West Africa has shown that such contracts are almost impossible to enforce. But opposition to the practice of native practitioners among Europeans has arisen. Since 1921 Dr. M. I. Molema has been practising in Mafeking, and has operated on European and native patients at the Victoria Hospital. From the beginning the nursing staff (all of whom are European) have shown resentment at having to take orders from an African when dealing with a white patient. Some six months ago they made a strong protest against Dr. Molema's operating on white patients while they had to assist at the operations and subsequently nurse the cases. As a result of that protest he ceased sending in European patients, but recently he again began sending such cases into hospital. When the third case, a girl of 19 years, arrived, the matron and nurses resigned in a body. That was on March 25th. The Mafeking Hospital Board in telegraphing the decision of the staff to the Administrator of the Cape Province stated that they were in sympathy

with the nurses. Though the staff has resigned, it is still carrying on the essential nursing services. After its resignation the hospital board again telegraphed to the Administrator a request that a section should be added to the hospital ordinance giving hospital boards the right to draw up a list of medical practitioners who were permitted to treat private patients in the hospital; urgent cases from other districts, however, always to be admitted.

Dr. Molema is the son of a chief of the Baralong tribe and car[illegible] Mafeking. He graduated M.B., Ch.B. [illegible] in 1919; he served during the war at [illegible] pital, Dublin, and subsequently at the Dublin Skin and Cancer Hospital. At Dublin he acquired a diploma in midwifery; he spent in all seven years overseas, returning to his native town of Mafeking in 1921. What the outcome of this local trouble will be is not yet clear, but it is significant of the growing opposition of the European community to the treatment of white patients, more particularly females, by native practitioners. Great publicity is being given to the trouble at Mafeking in the daily papers.

Scotland.

Treatment of Cancer.

At the annual meeting of the Royal Hospital for Home Relief to Incurables, Sir David Wallace, K.B.E., consulting surgeon to the Royal Infirmary, said that the society, which already dealt with late cases of cancer, which were incurable, might do something to assist in letting people know of the great importance attaching to early recognition of the disease. The report stated that the society began its work of relieving necessitous or deserving persons suffering from incurable disease 122 years ago. Nearly 500 sick persons in all parts of Scotland were at the present time receiving aid from the society, and the amount paid to annuitants during the year had been £4,897. The rate paid to incurable cancer patients under the Dunlop Fund managed by the society was £16 a year, and the total amount paid to annuitants suffering from this disease was £1,584.

The Hospital and the Home.

At a meeting of the Edinburgh Women Citizens' Association on May 18th Miss Nora Milnes, director of the Edinburgh School of Social Study and Training, gave an address dealing with hospital social service. She pointed out that although the country was provided with hospitals of unrivalled efficiency, a serious defect existed in the large number of men and women who had to be kept waiting for admission because of insufficiency of the beds. This problem could be dealt with in one of two ways. The more obvious method was to provide more hospitals and more beds, which, however, would entail a large capital outlay. A better and cheaper method was to see that when patients left the hospital their own home conditions were changed, so that an early return of the ailment should be improbable. A great deal of time and money at the present time was wasted because the patients left the hospital to return to homes in which convalescence was impossible, or to take up work unsuitable for their particular constitution. This could to a large extent be avoided by co-operation between the social and the medical expert. Doctors and nurses had not time to undertake this work, and a third person was required who possessed a special knowledge of social conditions and an understanding of the home environment of the patients. The scheme for trained social workers originated in London, when the first lady almoner was appointed to the Royal Free Hospital in 1895. In 1905, largely through the effort of Dr. Cabot, work had been started in America, and in Great Britain the idea had spread rapidly. Scottish hospitals in this respect were behind the times. The Maternity Hospital and Sick Children's Hospital in Glasgow had had lady almoners for some time, and within the last two years the Royal Infirmary of Edinburgh had appointed a lady almoner with two junior assistants. These provisions were, however, inadequate. The social worker must work under the doctor, and should, therefore, be appointed by the hospital, her duty being social diagnosis. Only through the co-operation of the two attempts could a cure be made real, and such united effort would enable the funds of hospitals to be spent to the best purpose.

Central Scottish Infirmaries.

At a meeting of Falkirk Dean of Guild Court on May 26th the plans were passed for the new Falkirk Infirmary, which is to be built on ground acquired at Gartcows, at an estimated cost of £100,000. The trustees of the infirmary are at present proceeding with the erection of five ward units and an administrative block, together with connecting main corridors. The buildings are to be constructed mainly of brick and concrete with freestone facing. The directors of Stirling Royal Infirmary are making an appeal for funds in aid of the new infirmary. The total amount required is estimated at £100,000, of which £75,341 has been already collected, including a sum of £9,500 paid by the education authority for the old infirmary. A further sum of £10,500 is to be received in grants for the maternity home. The new buildings are well advanced and it is expected that they will be ready for occupation by the summer of 1928. The directors of the Northern Infirmary, Inverness, have resolved to commence the reconstruction of the institution, at a cost of £100,000, of which £60,000 has been raised, the bulk of the money having been contributed by residents in various burghs and parishes in the North of Scotland. It has been decided to proceed at once with the erection of a children's ward, two central wards, and operating theatres, with connecting corridors and kitchen accommodation. Mr. A. J. C. Hamilton, M.B., F.R.C.S., has been appointed surgeon to the infirmary, in place of the late Mr. James Luke. Mr. Hamilton, who on graduation at Edinburgh University was awarded the Cunningham memorial medal and prize in anatomy and the Annandale gold medal in clinical surgery, at present holds appointments as clinical surgical tutor in the Edinburgh Royal Infirmary and senior clinical surgical assistant in the Royal Hospital for Sick Children, Edinburgh.

Edinburgh Royal Infirmary Pageant.

The annual public effort by Edinburgh citizens to collect funds on behalf of the Royal Infirmary took place on May 28th. The event was favoured by fine weather, and from early morning collectors were busy in the streets and in a door-to-door canvass of the suburbs. A special feature was the effort made by students of the university, dressed in all kinds of bizarre costumes. They offered a ticket conferring the degree of "Bache[illegible]" [illegible] the price of 5s., and this diplom[illegible] against any further appeals by [illegible] In the afternoon a great pagea[illegible] horse-drawn vehicles, staging various tableaux, paraded through the streets and collected money from the assembled crowd. Altogether the amount received was £4,200, an increase of £1,200 on the figure for last year, when owing to the industrial crisis the amount was unusually low; several auxiliary celebrations have been held in country districts, and when these have all come to hand it is expected that the total amount to be received by the Royal Infirmary will not fall far short of £7,000.

New Glasgow Dental Hospital.

At the annual meeting of the Incorporated Glasgow Dental Hospital, held on May 16th, the adoption of the report was moved by the Lord Provost, who presided. It was intimated that the governors had secured a site for a new hospital at 201, Renfrew Street, and that plans had been prepared which would give to Glasgow and the West of Scotland the finest dental hospital in the kingdom. An appeal to the public would shortly be launched for funds to provide the necessary £90,000. During the past year there had been 53,966 attendances of persons who were unable to pay dental fees.

Ireland.

MEDICAL CERTIFICATES IN SCHOOL ATTENDANCE CASE.

AT Millstreet District Court, in a case under the School Attendance Act, a letter was read from Dr. Elizabeth Murphy, Ballymackeera, Macroom, stating that she had attended the children concerned. Their father had applied to her for a medical certificate, which she refused for the following reasons:

1. She is not obliged to issue such certificates under the Medical Charities Act.
2. The medical officers of Macroom Union resolved not to issue such certificates, as no provision has been made for medical certification under the School Attendance Act.
3. In other countries special officers, including medical officers, are paid and appointed to carry out the provisions of the Act at the expense of the State.

The position taken up by Dr. Murphy in this case is in accordance with the law. Poor Law medical officers as such are under no statutory obligation to supply gratuitously medical certificates for the purposes of the School Attendance Act. Although medical certificates are *admissible and desirable, the district justices are empowered*, on other evidence being produced, either to impose a fine or dismiss without their production.

CHILDREN'S SUNSHINE HOME.

In the course of the annual report of the committee of the Children's Sunshine Home, Stillorgan, it is stated that very great encouragement was given by the visit of inspection by Sir Robert Jones, arranged by Sir William Wheeler, last November. Sir Robert expressed himself very much pleased with the treatment of the children, the arrangements of the home, and the nature and methods of the curative work carried out in it. Like the committee, he hoped for its eventual extension, and in the meanwhile regarded it as the start of a new movement, and a centre for the education of the public mind in curative endeavour of this nature. He expressed himself convinced that modern treatment could only be carried out in hospitals outside the city. An additional room for the artificial sunlight lamp was provided by Mr. and Mrs. Charles Jacob. The lamp, with its engine and dynamo, has been installed and is now in constant use. But with this addition to the curative means at disposal, it has been necessary to add another trained nurse to the staff, as well as a whole-time man to attend to the engine, furnaces, etc. Subscriptions to meet the increased current expenses, and donations towards the cost of the new buildings are urgently needed.

England and Wales.

MEETING OF THE MEDICAL WOMEN'S FEDERATION IN MANCHESTER.

THE half-yearly meeting of the council of the Medical Women's Federation was held at Manchester on May 12th to 14th, the President, Dr. Christine Murrell, in the chair. The President, Dr. Murrell, and the Vice-Presidents, Dr. Clara Stewart and Dr. Ellen B. Orr, were re-elected for a second year of office. The question of the right of the local associations of medical women, constituting the Federation, to issue publications of any sort independently of the Federation, was raised, and after considerable discussion it was decided that no local association could publish anything in the name of the Federation until the consent of the council had been given. Reports were received from the various committees of the Federation and from representatives of the Federation on committees of the British Medical Association and other outside bodies. The Venereal Diseases Standing Committee had prepared a pamphlet dealing with the duty of the State in the control of venereal diseases. This was referred to the local associations for their consideration before publication. Appreciation was expressed of the report of the League of Nations on the traffic in women and children, and a resolution was passed stating that the council of the Medical Women's Federation hoped that the Committee of the League of Nations would continue its investigations from the health point of view, since they were convinced that such investigation would demonstrate the medical futility of the whole regulation system. This council also recorded its unshaken belief that the non-compulsory system in force in Great Britain and Holland had produced, and promised to produce, the best results. A protest was made against any attempt to graft on any form of compulsion or to reintroduce the hurtful association of the control of venereal disease with the police. The Standing Committee for the Defence of Married Medical Women reported that a meeting had been held to consider what steps might be taken *to support the proposed Married Women's (Employment)* Bill. The proposal to get up a petition to Parliament was considered, but in view of the shortness of time it was considered that individual letters to members of Parliament from constituents would be more useful. This was advised, and many such letters were written. The Menopause Subcommittee had drawn up two questions in order to conduct an investigation on a wide scale into the phenomena of the menopause. These were being widely circulated and valuable results were expected. The question of underpaid posts was dealt with in the report of the Standing Committee on Public Health. To aid in dissuading women from accepting "blacklisted" posts a pamphlet, which had been drawn up by the Standing Committee, was considered and passed by the council. This will be distributed to newly qualified medical women and D.P.H. students, and be sent also to deans and secretaries of medical schools and others. Cases of underpaid posts applied for or accepted by medical women during the last six months were reported. In all cases where the names could be obtained the candidates were approached; several of these had shown great public spirit and had retired in consequence. While regretting that some women had accepted these posts, the council was pleased to note that no member of the Federation was among them. A new Standing Committee on Psychological Medicine was formed, after consultation with the representative of a group of medical women specially engaged in this branch of medicine, and discussion on the present position of medical women in asylum posts. Reports were received of the work of the Benevolent Fund, of the Medical Women's Federation Loan Fund, and the John Rains Memorial Loan Fund administered by the Federation. It was shown that these funds had been very useful, and were much appreciated. It was reported that the sum subscribed to the Dame Louisa Aldrich-Blake Memorial Fund amounted to £267, and a cheque had accordingly been sent to Sir Alan Anderson, honorary treasurer of the fund.

VICTORIA HOSPITAL FOR CHILDREN, CHELSEA.

The Victoria Hospital for Children, Tite Street, Chelsea, was founded in 1866, and, in connexion with its diamond jubilee, a special appeal for further support was launched; a deficit of £8,561 was reduced to £2,936. In the sixtieth annual report mention is made of the establishment of a special ward which renders it possible to retain under skilled supervision for twenty-four hours children who have had operations for the removal of tonsils and adenoids. The continued growth of the work of the artificial light and massage departments has necessitated expansion, and a new building has recently been constructed. The provision of private wards for children of parents who can afford to pay a special charge for this accommodation has proved very popular. Negotiations have been in progress with the London County Council for the treatment of school children for tonsils and adenoids, and for tuberculosis, other than the pulmonary form; the question of providing for their artificial light and convalescent treatment is also under consideration. During the year under review 1,677 children were admitted to the hospital, an increase of 337 on 1925; there was a reduction of over £3 3s. in the average total cost of each in-patient. A slight drop occurred in the average number of patients resident at the convalescent home at Broadstairs. A local committee has been formed to assist the home, and in the first year of its existence over £300 was raised.

WOODFIELD NURSING HOME, OLDHAM.

A new nursing home for Oldham is being provided by the adaptation of Woodfield, a house situated in a well wooded estate, which at one time belonged to the late Lord Emmott. It has been presented by Dame Sarah Lees, who has taken an active interest in public life in Oldham since 1890, and was mayor of the borough in 1910-11. When the reconstruction of the building is complete there will be accommodation for seventeen patients. A large well lighted operating room is being equipped and one wing is allotted to the nursing staff. Electric light is supplied throughout the establishment and the sanitation has been entirely reconstructed. The home will be managed by a committee, which will include the governors of the Oldham Royal Infirmary and the Nursing Association, together with local medical practitioners. Although it is not intended to seek to make a profit, the terms have been fixed so as to ensure its being self-supporting.

Correspondence.

RHEUMATIC INFECTION IN CHILDREN.

SIR,—In his "Notes on juvenile rheumatism" (May 28th, p. 952) Dr. Reginald Miller gives further evidence of his "*driving power*," *which Sir Humphry Rolleston recognized* in the preface to the first report of the special subcommittee of the British Medical Association.

All of us who have studied the two reports of the British Medical Association and that of the Medical Research Council will find this comparison of these reports a further welcome stimulus.

In his present paper Dr. Miller deals with six chief points of contact between the first report of the British Medical Association and that of the Medical Research Council, and, in regard to two of these, notes that "agreement appears to be lacking." These issues are still *sub judice*. But on the remaining four points he notes "it may fairly be claimed that agreement is shown."

The reports dealt with emanate from important bodies; the contributors to them are widely recognized as medical authorities, and correspondence of results in the two separate and distinct reports must carry great weight. It is consequently important to be very accurate regarding facts.

1. *The Influence of Social Status.*

As a result of the agreement he finds between the two reports on this point Dr. Miller states: "It may therefore be held to be established that juvenile rheumatism is a disease of the poor, but not particularly of the poorest."

"Juvenile rheumatism" is a wide term. In the report of the Medical Research Council Dr. Still states that the term "rheumatism" accepted there is: "only cases which either at the time or in their past history showed such pronounced evidence of rheumatism as to leave no doubt of their character; the majority, therefore, were cases with heart disease or chorea; cases of joint disease were only accepted as 'rheumatic' when they were either associated with heart disease or chorea, or were of the acute character known as 'rheumatic fever.'" The figures he gives from King's College Hospital and from private practice also deal with gross rheumatic lesions.

The subcommittee of the British Medical Association dealt with "rheumatic heart disease in children." It states "that in London acute rheumatism is practically confined to the poorer classes. There is no dispute about this fact. Hutchison may be quoted as having recently confirmed this. . . ." Other references are also given, and figures regarding overcrowding and cleanliness.

It would appear, then, that by the term "juvenile rheumatism" we are to understand gross rheumatic signs, and in so far as it is advisable to "avoid the wholesale notification of thousands of cases" this appears a wise limitation. But to state as established that juvenile rheumatism in all its various clinical manifestations is a disease of the poor would, it appears to me, go beyond the ascertained facts both of the committees and of clinical work. Dr. Still and Dr. Hutchison see few severe or advanced cases of rheumatism in private work, because doubtless there are few of such cases to see. But both must see many private cases where a doubt or a fear as to rheumatic infection is present, where great therapeutic care appears indicated and is taken, where as a rule there is no untoward development, but where occasionally uncompromising rheumatic signs develop. I would put it to Dr. Miller that while it can hardly "be held to be established that juvenile rheumatism is a disease of the poor" it could be more accurately stated that juvenile rheumatism under satisfactory conditions can usually be controlled.

2 and 3. *The Influence of Heredity and of School Environment.*

Frankly, the figures in neither report appeal to me as proving anything regarding heredity—either for or against its importance. Any agreement on the matter is simply that there is no accurate knowledge. So far as the report from the British Medical Association is concerned, I can find nothing more precise and original in it than the sentences on page 7 quoted by Dr. Miller, and this reference is, after all, merely a pious opinion of Dr. Miller's. True, in the report of the Medical Research Council it is stated by Dr. Still that "no sufficient evidence of heredity was forthcoming," and this somewhat ambiguous conclusion was arrived at as a result of much painstaking work and many mathematical calculations. But when we examine the nature of the work on the results of which the calculations were based we read (p. 12):

> "At the Children's Hospital, Great Ormond Street, all but 30 of the siblings of the rheumatic patients were actually examined by the medical officer. At the Royal Hospital for Sick Children, Glasgow, 118 were not examined owing to absence from home, etc. At St. Thomas's Hospital, owing to the fact that the medical examinations were carried out in hospital, 537 of the brothers and sisters of the rheumatic children and 117 of the siblings of the control cases were not actually examined."

On page 14 we read:

> "At St. Thomas's Hospital, although the mothers were seen by Dr. Forest Smith and Dr. Hamilton, it was not found practicable to examine them all medically, but they were closely interrogated as to their rheumatic history. It was also not possible to examine the fathers; their histories were obtained from the mothers. In many cases information as to health in childhood (especially of the fathers) was scanty or unobtainable; in others, the grandmother or other relatives were consulted to verify dates, etc."

We can but admire and agree with the ambiguity of Dr. Still's final conclusion, but it is hard to discover how Dr. Miller can obtain satisfaction from the "agreement" of the two reports on this matter. Dr. Miller then passes from the hereditary aspect to consider home environment, and as we may pardonably conclude that the former influence is still indeterminate, pre-rheumatic constitutional and environmental conditions must be of vital importance.

Dr. Carey Coombs, speaking of the rheumatic diathesis, says (*Rheumatic Heart Disease*, p. 20):

> "My own experience has not taught me to recognize any well defined type. The thin, eager, excitable child described by some writers as being prone to rheumatism is already rheumatic. . . ."

On the other hand, the late Dr. John Thomson wrote (*Clinical Study and Treatment of Sick Children*, p. 769):

> "In our dealings with cases which present any of the phenomena of rheumatism, we have always to bear in mind that the illness depends largely on the presence of a peculiar constitution or diathesis, and that the treatment of this is even more important, and certainly much more difficult to have carried out, than the management of its temporary manifestations."

Dr. H. C. Cameron seeks a middle path, and while of opinion that (*Diseases of Children*, p. 94):

> ". . . a catarrhal tendency, inherited and inborn, is very frequently met with . . ." he (p. 95) "leaves open the question of how far the tendency is due to inherited weakness and how far it is the result of faults of diet and of hygiene," and says, "The truth appears to be that in the lymphatic and catarrhal child, with the characteristically low immunity *against all infections*, either tuberculosis or acute rheumatism may appear as a later development."

There is, I think, wide clinical evidence of a pre-rheumatic constitutional peculiarity or abnormality, and Rosenow's work on streptococci emphasizes the importance of the recognition of this. It is doubtful if it is specific, and it may be impossible to mark the line of actual rheumatic infection.

In a leading article of the BRITISH MEDICAL JOURNAL of May 14th on "The constitutional factor in disease" it is stated: "George Draper has been working on the same lines as Kraus for some six years at the Presbyterian Hospital, New York, and regards constitution as 'the aggregate of hereditary characters influenced more or less by environment, which determines the individual's reaction, successful or unsuccessful, to the stress of environment.'" The "home" as opposed to the "school" must be the all-important environment, particularly in the early years of life, because we know, through the apparent absence of the disease in babyhood, that constitutional development or physical growth and experience is necessary as a preliminary to rheumatic infection.

As, however, the children in the four Poor Law institutions of the Medical Research Council report were certainly "children of the poor," and yet escaped the disease, it appears incorrect to speak of a "rheumatic stratum of society," but, again, better to say that under satisfactory home conditions the development of juvenile rheumatism can usually be prevented.

4. *The Influence of Tonsillar Disease and Tonsillectomy.*

I am whole-heartedly with Dr. Miller in hoping that the two reports will conduce to more complete treatment of infected tonsils. I also, however, most sincerely hope that the criterion of health or otherwise of a tonsil accepted by the committee of the Medical Research Council may not be that to be depended upon. On page 31 of this report it is stated:

> "In two centres—namely, the Children's Hospital, Great Ormond Street, and the Royal Hospital for Sick Children, Glasgow, the variation in the size of the tonsils has been taken as the criterion of their unhealthiness or otherwise. They have been recorded, in most cases, as small, medium, large, and very large. The 'large' and 'very large' have been classified as unhealthy and the others as healthy in the absence of any remark to the contrary."

I would assure Dr. Miller that, while I may appear to be attempting to pick holes, this letter is determined rather by recognition of the valuable work he has done and is doing, and with the hope that it may be carried to full fruition.—I am, etc.,

Liverpool, May 28th. A. DINGWALL FORDYCE.

SIR,—The comparison of the reports on juvenile rheumatism by Dr. Reginald Miller (May 28th, p. 952) is of great interest, especially the part in which he emphasizes the novel evidence put forward in the report of the Medical Research Council with regard to the non-appearance of rheumatism in Poor Law institutions.

As a member for many years of the local board of guardians, I took an interest in the children in the cottage homes, and was the means of introducing a system whereby every case of sickness was properly investigated. During that time all sorts of diseases occurred among the inmates, but never a case of rheumatism, chorea, or their sequel, heart disease. In these homes there was nothing in the form of luxury, but the food was good, in fact of a standardized quality. The following is a list of articles of diet, with the minimum amount for one child a week.

Bread 7 lb.	Butter 8 oz.	Oatmeal 3 oz.
Bacon 2 oz.	Eggs 3	Sugar 8 oz.
Suet or lard 2½ oz.	Jam 1 oz.	Cocoa 2½ oz.
Peas 3 oz.	Cake 4 oz.	Flour 12 oz.
Tea ½ to ¾ oz.	Beef, pork, or mutton, uncooked and free from bone 18 oz.	Vegetables 2 lb.
Milk (new, unskimmed and undiluted) 5 pints	Potatoes 3 lb.	Currants 2 oz.
Cheese 4 oz.		Rice 2 oz.

From this list it will be seen that each child gets at least 5 pints of milk (good milk), together with 4 ounces of cheese, 8 ounces of butter, and 3 eggs, with the result that each boy and girl is well supplied with lime-containing substances, and nothing in the form of vinegar, pickles, or sauces to reduce the quantity of lime in the body appears on the list.

These facts tend to emphasize my contention that every case of rheumatic fever or chorea arises from what I call the "acid or acid-taking" class, by which I mean that class of child who does not take milk, either through poverty or dislike, and aggravates this lack of lime-containing food by a partiality for acid or sour things.

The report of the Medical Research Council, by its statement that "want of maternal care" has much to do with the causation, seems to corroborate the conclusions at which I have arrived. If all investigators will agree that this subclass supplies all our cases of heart disease, we shall have achieved something substantial.—I am, etc.,

Swansea, May 31st. G. ARBOUR STEPHENS.

PROPHYLACTIC VACCINATION OF THE NEWLY BORN AGAINST TUBERCULOSIS.

SIR,—With reference to the second sentence of Professor Calmette's letter (May 28th, p. 987) I would point out that my criticism of what, as Professor Calmette explains, was the whole of Dr. Biraud's report to him was directed to the omission of details which, in my opinion, ought to have been published. I did not criticize Dr. Biraud's method of analysis; I think it was adequate and that no other statistician would get more out of the material than Dr. Biraud has already obtained.

The issues raised by Professor Calmette's work are, however, so important that I must ask your permission to expand my other criticism to which Professor Calmette does not refer. On page 210 of Professor Calmette's paper[1] there is an (italicized) assertion that, in France at least, 25 per cent. of children of tuberculous mothers or of children reared in contaminated surroundings die of tuberculosis in the first year of life. Let us examine the evidence upon which Professor Calmette relies. On page 206 he states that of 1,364 children reared under the stated conditions, 327 (24 per cent.) died in the first year "d'affections présumées tuberculeuses"; but we are not told what were the grounds of the presumption, what was the rate of mortality from *all* causes in the first year of life, and how the cases were chosen. On page 208, Strauss is cited as authority for the statement that of 6,820 children dealt with between 1906 and 1911 in Paris 3,429, or 50.28 per cent., died. We are not told whether this is the mortality of the first year or of the first five years of life, or what proportion of the deaths were due to tuberculosis. As the annual deaths of children aged 0 to 1 ascribed to tuberculosis in Paris numbered 213 in 1913, 168 in 1921, and 154 in 1922, 3,429 in five years would be more than six times the whole recorded mortality, so it is hardly credible that Strauss is referring to deaths from tuberculosis at 0 to 1. This evidence is, therefore, irrelevant.

On page 210 Weinberg is said to have found that in Stuttgart (1873-89) 30.52 per cent. of the children of tuberculous mothers died in the first year of life, but it is not mentioned that Weinberg (*Die Kinder der Tuberkulösen*, p. 58) also found that the death rate of the children of non-tuberculous mothers was 23.82 per cent., so that the excess mortality of the infants of the tuberculous was 6.70 per cent. These figures, which relate to mortality from all causes, have no direct relevance to Professor Calmette's contention, but Weinberg's very careful study does actually contain some relevant material which Professor Calmette has not quoted. The sixteenth chapter of Weinberg's book deals with the specific mortality of the children for the period 1873-1902, and I note these points. Considering only the children born within five years of the death of a tuberculous parent, 1,477 deaths occurred in the first year of life, and 84 of these deaths were certified to be due to tuberculosis. Assuming this to be an under-statement owing to imperfect certification, and making a liberal allowance for the understatement by multiplying by three, we reach 252, which is 17 per cent. of the total deaths.

Passing now from deaths to rates of mortality, I find that the rate of mortality from tuberculosis would be about 7 or 8 per cent., not 25 per cent. Now this estimate is in reasonable agreement with that of Kjer-Petersen and Ostenfeld, based upon a much smaller but more closely verified set of data. The maximum rate in their series (obtained by crediting the "doubtfuls" to tuberculosis) is 6.1 per cent., and the Upsala data of Bergman, quoted by

[1] *Annales de l'Institut Pasteur*, March, 1927.

them, give (when similarly treated) percentage mortalities ranging from 5.2 to 9.6. Dörner, who investigated tuberculosis in families in a district of Baden (see *Beitrage z. Klinik d. Tuberkulose*, xx, 1911, p. 20), gives the mortality from tuberculosis over the first *two* years of life as 17.1 per cent. when both parents died tuberculous, 8.7 per cent. when the mother only died of tuberculosis, 5.8 per cent. when the father only died of tuberculosis, and 1.9 per cent. when neither parent died of tuberculosis. All the evidence I have seen supports the view that both general and specific mortalities are higher amongst the children of the tuberculous than amongst the general population of children; none of it suggests that the excess specific mortality is of the order claimed by Professor Calmette. The importance of the point is obvious: if we have to do with a difference only of the order of a few per cent., we shall certainly need much larger compared samples in order to reach any satisfactory conclusion than would be the case if Professor Calmette's contention could be established. I suggest that the evidence he has tendered on this point is wholly *insufficient* to carry conviction.—I am, etc.,

MAJOR GREENWOOD.

Longhton, May 29th.

SYMPATHETIC INNERVATION OF STRIPED MUSCLE.

SIR,—In your editorial article of April 30th (p. 803) you very rightly bring again to the notice of surgeons the work of Royle and the late John Irvine Hunter in the treatment of spastic paralysis.

I should like to draw attention to the histological basis of the theory of the double innervation of striped muscle, as put forward by Hunter. He postulates the existence of two types of muscle fibre, one of which is solely innervated by sympathetic fibres, and the other solely by somatic fibres. This was based on Kulchitsky's work published in 1924 (*Journ. Anat.*, vol. lviii, 153). Boeke, who, on the other hand, commenced publishing work on this subject in 1909 (*Anat. Anz.*, 35, 193), holds that single muscle fibres are innervated by both sympathetic and somatic nerve fibres.

You quote Boeke as supporting the histological basis of Hunter's theory. In his most recent paper Boeke (1927, *Zeit. f. Mikr. Anat. Forsch.*, 8, 561) confirms his position with a wealth of diagrams, and states that it is certain that all striped muscle fibres receive a somatic innervation. This is quite contrary to Kulchitsky's observations, and to the theory as expressed by Hunter—that there is a type of striped muscle fibre which is innervated solely by the sympathetic fibres. In this paper Boeke concludes that, in opposition to the statement by Hunter and Latham, a spinal innervation to the thin protoplasmic rich muscle fibres was undoubtedly proved by degeneration methods.

While, therefore, the theory of a double function in striped muscle associated with its double innervation, somatic and sympathetic, may be gaining weight, the histology of the question is by no means so simple as would be inferred from your editorial article.

A further statement of the position and some evidence against the general acceptance of a type of innervation such as Kulchitsky found in snakes can be seen in my paper in *Brain* (1925, xlviii, 380).—I am, etc.,

H. S. D. GARVEN, M.D.

Moukden, Manchuria, May 19th.

UROGENITAL TUBERCULOSIS.

SIR,—There is one dogmatic statement in Mr. Nitch's otherwise instructive and interesting lecture (BRITISH MEDICAL JOURNAL, May 14th, p. 863) to which exception may be taken. He states that "in all cases tuberculin is of great value, but only after operation." I suggest, on the contrary, that tuberculin is sometimes so valuable before operation that all indications for operative treatment disappear; but on the other hand I doubt whether it is "in all cases of great value." It would be easy to quote from the literature and my own practice a considerable number of cases in support of these opinions, but one of my own cases may suffice at the moment.

Two years ago I showed a patient at a clinical meeting of the Manchester Medical Society for the purpose of illustrating the apparent value of tuberculin after operation had failed, and incidentally to suggest that it may sometimes render an operation superfluous. The history of this case is briefly as follows:

A man, aged 39, developed tuberculous epididymitis early in 1919. His left testicle was removed at the Manchester Royal Infirmary in June of that year. In May, 1920, he was referred to me for tuberculin treatment by Dr. H. F. Lee (Manchester), as the disease had developed in the right epididymis. He was febrile; there was a discharging sinus in the operation scar on the left side and the right epididymis was enlarged and tender; it subsequently broke down and discharged considerably from several sinuses for over a year. He became afebrile after six weeks' rest in bed. Tuberculin (BE) was then begun in very small doses (1/50,000 mg.) and cautiously increased. The maximum dose eventually reached about a year later was 1/1,500 mg. He returned to business after he had been under this treatment seven to eight months, as he had then regained weight and his general condition was very much improved. The subsequent history was that of steady improvement. He is now, at the end of seven years, in good health; all the sinuses are soundly healed. He still comes up occasionally for a prophylactic inoculation.

While a result of this kind is seen occasionally in genito-urinary cases, my experience is that glandular lesions give the most uniformly successful results. May I suggest in conclusion that, if it be agreed that appropriate tuberculin *inoculations* increase the resistance of some patients to the disease, there are valid theoretical grounds for adopting this treatment prior to operation in all afebrile cases, mainly in order to reduce the risk of disseminating the disease, which, I am inclined to think, sometimes happens as an immediate consequence of an operation. It is also well to have clearly in view the fact that an unpromising case may make, now and again, a surprisingly good response to tuberculin treatment, and that a contemplated operation may in such circumstances be avoided.—I am, etc.,

Manchester. J. STAVELY DICK.

AURICULAR FIBRILLATION.

SIR,—In view of the correspondence which has been taking place in the JOURNAL on the subject of auricular fibrillation, I will relate my personal experience.

My first attack of irregular cardiac action was while I was playing golf at Atherston in the early nineties; it quite spoiled my play for the time: occasional attacks came on at irregular intervals (five or six weeks) and often while sitting quietly or after meals. I remember one attack while on the Riffel Alp, which I attributed to the altitude. In the following year I had a bad attack while on a long cycle ride in Shropshire, in a hilly and difficult country. From these attacks I quite recovered, and was able to go about my duties and make my usual exertions without trouble. By degrees, however, the attacks became more frequent and I sought advice from many well known and "special" medical men. "Quot homines, tot sententiae:" some said indigestion, others nervousness, others arterial tension, and I was ordered valerian tea instead of tea or coffee for breakfast, sodium bicarbonate before meals, and 1/20 grain of calomel three times a day.

In 1912 I retired and went to reside at Eastbourne. In 1914 a friend gave me Bergonié's treatment; the damp cold cloth at my back produced a chill and I developed cystitis, which laid me up for some weeks, with the added discomfort of bacillus coli. The attacks of fibrillation ceased and have never recurred, but a slight irregularity of the pulse exists, with a rate of about seventy.

Until eighteen months ago I cycled regularly, but owing to lameness in my left hip I have been obliged to abstain from that mode of progression. I consulted Sir James Mackenzie in 1912, and at first he did not recognize the disease, and not until he had had electro-cardiograms taken did he announce that my disorder was auricular fibrillation.—I am, etc.,

Eastbourne, May 23rd. MILNER MOORE, M.D.

DRUGS FOR SLEEPLESSNESS.

SIR,—May I add my experience of the use of medinal to that of Sir Maurice Craig?

During the past eight years I have given medinal to over two hundred patients in doses of from 5 to 8 grains nightly over periods ranging from a few weeks to several

months. The patients were all suffering from neuroses or mild psychoses. I have found it a most valuable drug; all patients have been under my close observation in a nursing home, and I have never seen any ill effects from its use, and although I keep in touch with patients after they leave my care, I have never heard of a case where its use was not readily discontinued. Under proper supervision medinal is a most valuable hypnotic, and it would be a great misfortune if its use should be discredited.—I am, etc.,

Chobham, Surrey, May 31st. CHARLES H. CALDICOTT.

POST-MORTEM EXAMINATIONS IN GENERAL PRACTICE.

SIR,—I would submit the following points for consideration:

1. In the majority of cases conditions found *post mortem* are not exactly those that were expected, even though the diagnosis is confirmed. Generally there is more, or there is less, than was thought to exist. Sometimes the doctor has a severe shock, sometimes he goes away from the *post-mortem* room completely mystified.
2. A laboratory in close proximity to the *post-mortem* room is essential. If this is not provided much valuable information may be lost, and in many instances the whole point of the case missed.
3. *Post-mortem* examinations are a supplement to clinical work. Granted he has average knowledge of pathology, the man who has attended in life will form a truer view of the whole case than an expert who sees the dead body for the first time.

For these reasons, if the extension of the public health service that has been mooted is ever brought about, I would recommend that laboratories as well as pathologists be provided and that the medical attendant be present and have joint responsibility for the report, lest half the value of these examinations be lost.—I am, etc.,

Southend-on-Sea, May 29th. R. A. S. SUNDERLAND.

Medico-Legal.

THE LUNACY LAW: LIMITATION OF ACTIONS.

HARNETT *v.* FISHER.

SINCE the decision of the House of Lords in the case of Harnett *v.* Bond and Adam received consideration in our columns, Mr. Harnett has obtained the verdict of a special jury that he was sane on the date when Dr. Holdrich Fisher gave a certificate on which a reception order was made out, and that Dr. Fisher did not act with reasonable care in certifying him. Owing, however, to the fact that Mr. Harnett did not issue his writ within the period allowed by the appropriate Statute of Limitations, judgement was entered for Dr. Fisher by the trial judge, and this judgement was upheld both in the Court of Appeal and in the House of Lords. The proceedings at each stage have been recorded in our columns, and the judgement of the House of Lords was reported at some length in our last issue (p. 1036). It was considered advisable to do so because no such report has been published elsewhere, but the decision of the House of Lords was on a point of law, and no principle of medical importance arose.

The only question on appeal was the purely legal one, whether Mr. Harnett's right of action was barred owing to the lapse of time before he issued his writ. Consequently the three reasoned judgements delivered by Lords Sumner, Atkinson, and Blanesburgh—the remaining two members simply concurring—contain references of a highly technical nature to various sections of Acts of Parliament, the effect of which cannot be fully appreciated by those who are not lawyers.

The majority of the House decided that the defendant doctor had properly pleaded the Statute of Limitations, 21 James I, c. 16, and that, as the writ was not issued within six years of the date on which Dr. Fisher made his examination and signed his certificate, the action was barred by that statute. The certificate was given on November 10th, 1912, and from that date until October 15th, 1921, Mr. Harnett was, in fact, an inmate of various asylums. It was accepted by the House of Lords that between those years Mr. Harnett was unable to bring his action, and a peculiar legal dilemma arose from which Lord Blanesburgh, in particular, attempted to find a way out. The ancient statute of James I said that in the case of a person *non compos mentis* time would not run until after such disability ceased, and so Mr. Harnett pleaded that from the date he was certified until October 15th, 1921, he ought in law to be treated as *non compos mentis*. Thus we have the spectacle of a plaintiff asking a jury for a verdict that he was in fact sane, and asking a judge for a ruling that he was in law insane during the same period of time for the purposes of the Statute of Limitations.

On a "liberal" construction, the plaintiff urged, the statute should be read so as to bring such a case as his within the disability section. The trial judge and all the judges on appeal, however, came to the conclusion that the statute could not be construed in that sense. Lord Sumner bluntly said that it could not be so interpreted without wresting it from its language in a way that could not be permitted.

It may seem strange that the Statute of Limitations was running against Mr. Harnett's right of action during a period when, in fact, he was in an asylum and was unable to issue his writ; but, on the other hand, the medical profession, upon whose members rests the responsibility of administering the Lunacy Acts, would be unfairly placed if the alternative construction were adopted, and an action for negligence were suspended over the head of the giver of a certificate during the whole of the period of the certified person's confinement, however long that period might be, and for six years afterwards. Both Lord Sumner and Lord Blanesburgh realized that this alternative construction was impossible, but whilst Lord Sumner held that the hardship occasioned by this dilemma must be borne by the party who, upon the ordinary construction of the words of the statute, should bear it, Lord Blanesburgh sought a solution in the Public Authorities Protection Act, 1893. His solution amounted to this. The Lunacy Act of 1890, like its predecessor of 1845, contained a provision that all actions must be commenced within twelve months of the release of the party bringing the action. Dr. Fisher had pleaded this section, only to discover before the trial that it had been repealed by the Public Authorities Protection Act, 1893. It was in these circumstances that Dr. Fisher amended and pleaded the statute of James.

Because Section 82 of the Lunacy Act, 1890—giving a person who considered he had been unjustly confined as a lunatic the right upon discharge to copies of the certificates on which a reception order was made—remains unrepealed, Lord Blanesburgh was led to the conclusion that the twelve months' limitation prevailing from 1845 until 1893 was not abolished, but lived in the shorter period of six months laid down in the repealing Act of 1893.

In other words, whilst Lord Sumner and the other members of the House held that the plaintiff's right of action was barred by the Statute of Limitations running against him continuously from November 10th, 1912, to November 10th, 1918, when he was still in the asylum, Lord Blanesburgh held that the plaintiff's right of action was barred by the Public Authorities Protection Act, 1893, running against him for six months from the date of his release. Lord Blanesburgh's conclusion did not help Mr. Harnett, the writ in the action having been issued more than six months after his escape, although, had the remaining members of the House agreed, it might have gone towards helping future plaintiffs in a similar position.

Lord Blanesburgh's argument presumes, however, that a medical practitioner, in giving a certificate for the purposes of a reception order, is doing an act to which the Public Authorities Protection Act, 1893,

applies; but here he is in disagreement with Lord Atkinson. As was said by Lord Buckmaster in another case, there are duties and authorities which are not public, to the exercise and discharge of which the Act of 1893 does not apply. In Lord Atkinson's view, the giver of a certificate for the reception of an alleged lunatic owes no duty to the general public or to any public institution or authority—he is simply engaged as a medical man to give an opinion as to a patient's state of health. Therefore, the limitation of six months provided by the Public Authorities Protection Act not applying, Lord Atkinson fell into line with Lord Sumner's view that the appropriate Statute of Limitations was that of James, despite the words of Lord Blanesburgh that the statute of James was singularly unsuited to this claim.

Therefore it will be seen that an anomalous situation in our lunacy laws was created by the repeal of the twelve months' limitation laid down in the Act of 1890. The circumstances of this case—in which one member of the House of Lords finds a substitute of six months in a later Act, and the remaining members, disagreeing, are driven back upon a statute of 1623 which prima facie may work injustice to a plaintiff—provide another consideration to which the Legislature should give attention when, in the fullness of time, it shall find opportunity to amend the law, in order that justice may be done alike to the general public and to their servants, the members of the medical profession.

Obituary.

HENRY COOK, M.D.,
Surgeon-General, I.M.S.(ret.).

SURGEON-GENERAL HENRY COOK, Bombay Medical Service (ret.), died on May 30th, at the age of 95. He was educated at the Grosvenor Place Medical School, at St. George's, and at St. Mary's Hospitals, and took the M.R.C.S. in 1854 and the M.D.St. Andrews and M.R.C.P. Lond. in 1858. He was elected F.R.C.P.Lond. in 1883. He entered the Indian Medical Service as assistant surgeon on January 24th, 1855, over seventy years ago, he attained the rank of deputy surgeon-general on June 23rd, 1884, and retired on November 21st, 1886, with an honorary step in rank. In his early years he served in Persia in 1857, and in the Abyssinian war of 1867-68, gaining the medal for each. His subsequent service was chiefly in civil employ in Bombay Presidency, where he held professorships in the Grant Medical College, Bombay, for many years, first that of hygiene, and afterwards the chair of medicine, in combination with the principalship of the college, until his promotion to the administrative grade.

During the last twenty-three years he had lived at Lee-on-Solent. He was a Fellow of the Royal Geographical, Meteorological, and Geological Societies, and a J.P. for Gloucestershire. During his career in Bombay he had been for some time chairman of the Bombay Municipal Corporation. He leaves a widow, two sons, and two daughters.

Since the death of Deputy Surgeon-General P. W. Sutherland, on June 6th, 1925, Surgeon-General Cook had been the senior officer on the retired list of the Indian Medical Service. The Indian Medical Service was closed to competition from 1860 to 1865, and there are now only two officers left alive, or at least shown as living, in the Army List, who entered that service previous to 1860: Surgeon-Majors A. Gamack (Madras, 1856) and G. Henderson (Bengal, 1859). As the Crown took over the Government of India from the East India Company in 1858, Dr. Gamack is the only Company's medical officer now living.

We regret to record the sudden death, on April 28th, of Dr. JAMES WEIR STEWART of Kelvinside, Glasgow. While proceeding to visit a patient he was suddenly taken ill and was assisted to the police station at Old Monkland. A doctor was summoned and a restorative given, but in half an hour he succumbed, death being due to angina pectoris. He was educated at George Watson's College, Edinburgh. He graduated M.B., C.M. in 1885, and afterwards studied diseases of the eye in London. He practised in the north-western district of Glasgow for nearly twenty years. In 1908 he accepted the post of medical officer to the Scottish Mineowners' Defence and Mutual Insurance Association. During the war he did valuable work for the British Red Cross Society. He was of a generous and kindly nature and of a buoyant disposition. He was not only much respected but greatly beloved by all with whom he came into contact, and will be greatly missed for his many unrecorded deeds of kindness. Dr. Stewart was unmarried, but leaves a sister who resided with him.

DR. ALLAN WHITFIELD, who died on May 23rd at Babbacombe, was born in Shropshire in 1864, and received his medical education at Owens College, Manchester. He obtained the diplomas L.R.C.P., L.R.C.S.Edin., L.R.F.P.S.Glasg., and L.M. in 1895, and two years later the M.R.C.S.Eng. and L.R.C.P.Lond. For many years he carried on practice in Manchester, and during the war was a member of the recruiting board in that city. In 1921 he began to practise in Burton-on-Trent, but in the following year ill health compelled him to retire and live in the South of England. In 1924 he resumed active practice at Kingsteignton in Devon, but in 1926 he was again obliged to retire, and died after a long and painful illness. He was a member of the British Medical Association and of the Manchester Medical Guild. He is survived by his wife and one daughter.

DR. EDWARD LOFTUS CAMBIE, who died on May 28th at his residence in Templemore, Tipperary, was born on December 25th, 1869, and received his medical education at the Royal College of Surgeons and the University of Dublin. He obtained the diplomas L.R.C.S.I., L.R.C.P.I., and L.M. in 1892. He carried on medical practice for twenty-one years at Portsmouth, and previous to this in London. Dr. Cambie was a man of considerable ability, and was held in the highest esteem by all who knew him. He was a member of the British Medical Association until his retirement from practice.

Medical Notes in Parliament.

[FROM OUR PARLIAMENTARY CORRESPONDENT.]

THE House of Commons will reassemble on June 13th and resume the Committee stage of the Trade Disputes and Trade Unions Bill. The Vaccination Bill has been put down for second reading on June 15th. Time is not likely to be available for its discussion, but Dr. Fremantle, Dr. Watts, Sir Richard Luce, Sir George Berry, and Dr. Vernon Davies have put down a motion for its rejection.

Mr. Baldwin announced, on June 1st, that the House of Commons would probably adjourn about the end of July, but that it would have to sit again during the autumn to complete the business of the present session.

On June 2nd, on the motion that the House adjourn over Whitsuntide, Sir A. Steel-Maitland replied to a debate on the Geneva Convention on hours of labour. He said that the object and policy of the Government in regard to this Convention was as recently stated by the Earl of Balfour in the House of Lords, but that the Government had to get over the difficulties first. He pointed out that the French Government had interpreted the Convention in a way which would be impossible in this country. For instance, it had, by regulations under the French Eight Hours Law, enacted that railwaymen might be required to be in attendance for twelve hours, counting as eight hours' work. To clear up the difficulties would take some time. In Great Britain such cases as those of the crucible-iron workers and the tailors who were on piecework without set hours at all had to be met.

Later in the same debate Mr. Lansbury called attention to the imprisonment of Mr. Bose, town clerk of Calcutta, under the Bengal Criminal Ordinance. Earl Winterton (Parliamentary Under Secretary for India) said, in reply, that Mr. Bose was imprisoned for breaking the law against revolutionary crime. Some time ago his health was found to be unsatisfactory, and a conditional offer of release was made, which he refused. Shortly afterwards, further investigation was made into the condition of his health, and it was found that he had not

improved. It was not true to say that he was dying, but his health was not improving, and consequently the Government released him unconditionally.

Shop Acts, 1920 and 1921.

When the Committee which is considering the Shop Acts of 1920 and 1921 met on May 31st Dr. Marion Phillips and Mrs. Adamson gave evidence on behalf of the Standing Joint Committee of Industrial Women's Organizations. They said inquiries showed that there was no real demand for later hours in confectioners' shops. Girls employed were often extremely young, and suffered physically from the long hours. Instances were given of sickness and general debility among them.

The General Medical Council.—Answering Mr. Macquisten, on June 2nd, Mr. Chamberlain said he did not think that modern developments in therapeutics necessitated any revision of the powers and duties of the General Medical Council. He added that the Earl of Balfour shared this view. Mr. Macquisten, in his question, had asked for the appointment of a Royal Commission to inquire into the operation of the Medical Acts and the powers and privileges of the General Medical Council.

Number of Insured Persons.—Mr. Chamberlain announced that at the end of 1926 there were, exclusive of persons over 70 who had ceased to pay contributions, 9,857,000 males insured in England and Wales under the National Health Insurance Act and 4,658,000 females. Since the end of 1925 the increases were 251,000 and 68,000 respectively. In Scotland the comparable figures at the end of 1926 were 1,144,000 males and 571,000 females, being an increase in the year of 28,000. In Northern Ireland the figures for 1926 are not expected to show material change from those for 1925, which were 194,300 males and 139,700 females.

Notes in Brief.

The latest official information from the Bombay Presidency indicates that conditions continue to improve in the four districts affected by cholera. In the week ended April 30th, 1,092 attacks by, and 461 deaths from, cholera were reported in these districts.

In a reply to Mr. Groves, Mr. Chamberlain said he would not introduce legislation requiring parents who believed in vaccination to make a statutory declaration of belief in order to have the right to subject their children to it.

Mr. Chamberlain states that the substantive regulations dealing with the standardizing of vaccines and serums will be laid before Parliament, and will be available immediately after the Whitsun recess.

Mr. Baldwin has stated that no useful purpose would be served by setting up a Royal Commission on the financial difficulties of the voluntary hospital system.

The Minister of Health announces that it is proposed to instal artificial light treatment at the North Wales Sanatorium, Denbigh. Arrangements have been made for it at the Orthopaedic Hospital at Gobowen and at the Wrexham Dispensary.

A bill to provide for the humane slaughter of animals in Scotland was presented, on June 2nd, by Colonel Moore, supported by Dr. Drummond Shiels.

No women police doctors have been appointed in the Metropolitan Police area.

No standard tests are prescribed to ensure that imported condensed milk complies with the Public Health (Condensed Milk) Regulations, but tests are made at discretion by the Government chemist and by public analysts.

Universities and Colleges.

UNIVERSITY OF CAMBRIDGE.

AT a congregation held on June 4th the following medical degrees were conferred:

M.D.—C. H. C. Dalton, E. H. H. Granger, L. E. H. Whitby.
M.B., B.CHIR.—R. K. Debenham, R. L. Lancaster, R. D. Milford, J. H. Randall, R. E. Smith.
M.B.—H. V. Dicks, H. V. Coverdale.

UNIVERSITY OF LONDON.

THE following candidates have been approved at the examination indicated:

THIRD M.B., B.S.—*‡G [illegible] (Westminster medal)
‡E. A. Freeman, [illegible]
Louis, *‡J. M. Tu[illegible]
Anson, Cécile H. L[illegible]
D. E. Barton, A. D. Benbow, Joan M. [illegible]ackledge, D. A. Blount, Eleanor D. Blunt, Hilda M. P. Bond, D. G. Bown, D. A. Brigg, Muriel Brighton, Margaret H. Brown, Helen M. Browne, Helen R. B. Buck, T. S. Cochrane, A. Cohen, Mary C. E. Constantine, E. S. Curtiss, F. J. Darbyshire, G. I. Davies, T. E. Davies, J. Dean, A. E. de Chazal, Jean M. Dollar, Margaret R. Dunlop, M. H. C. Dyson, J. Evans, F. M. M. Eyt n-Jones, Dora J. Fox, A. E. Fraser-Smith, J. Gabe, B. M. C. Gil-enan, A. S. Gough, W. P. Greenwood, C. H. Hamp-hire, Kathleen Hoyes, H. F. Hiscocks, Janet I. Hoare, Joan Houseman, E. G. [illegible] Ledger, W. Leslie, A. H. Lev[illegible] Joyce McConnell, A. C. MacL[illegible]uende, J. W. Nankivell, Helen E. M. Newman, Joan Nixon, Marjorie E. Parfitt, S. M. Power, Marion Ravell, J. H. O. Roberts, L. Roberts, W. C. Robinson, Enid H. Rockstro, S. T. Seccombe, M. Sendak, J. Silverstone, K. S. Smith, G. E. F. Sutton, F. W. Ta'Bois, Kathleen E. Tresillan, Maeve Whelen, Elizabeth M. Whishaw, J. S. Whitton, H. E. Williams, B. H. H. Wooderson, E. Wornum.

* Honours. † Distinguished in Medicine.
‡ Distinguished in Pathology. ‖ Distinguished in Surgery.
§ Distinguished in Midwifery.

Group I.—Marjorie F. Brierley, D. A. Dewhirst, Phyllis M. Edgar, L. Fatti, A. Golombek, C. B. Huss, Caroline M. Kingsmill, F. E. Kingston, [illegible] H. Livingstone, W. E. Lock, He[illegible], Ethel E. M. Ogilvie, Evelyn P[illegible]et E. Peaker, K. R. T. Peiris, E. [illegible] Skipper, J. R. C. Spicer, Victoria [illegible] Thornton, Winifred M. Turner, [illegible] Williams, H. D. Wyse.

Group II.—G[illegible] V. FitzC. Anderson, C. G. Bowen, F. W[illegible] J. A. Cholmeley, Doris B. Clay, R. R. [illegible] R. Forrest, K. T. Gajjar, Dorothy Gode[illegible]bbes, K. H. Lachlan, M. L. Maley, W. D[illegible] M. Phadke, B. F. Russell, C. F. J. Smith[illegible] M. Stuart-Harris, Olive F. Sydenham, I[illegible] h, J. G. Weston, C. L. Worthington, Elsie B. Wright.

UNIVERSITY OF BIRMINGHAM.

DR. I. DE BURGH DALY, Lecturer in Experimental Physiology Welsh National School of Medicine, University of Wales, Cardiff has been appointed to the Chair of Physiology, vice Professor E. Wace Carlier, retired.

At the annual degree congregation to be held on Saturday, July 2nd, the honorary degree of LL.D. will be conferred upon the following members of the medical profession: Sir David Ferrier, F.R.S., Sir Watson Cheyne, Bt., K.C.M.G., F.R.S., and Sir Walter Fletcher, F.R.S., secretary of the Medical Research Council.

ROYAL COLLEGE OF SURGEONS IN IRELAND.

AT the annual meeting of the Royal College of Surgeons in Ireland, held on June 2nd, a resolution was adopted unanimously thanking Mr. R. Charles B. Maunsell, the ex-President of the College, "for the admirable and successful services he rendered the College, and, indeed, the profession in Ireland in general, in connexion with the settlement of medical registration in the Free State, after consultation with the members of the Executive Council of the Dail."

The Services.

INDIAN MEDICAL SERVICE DINNER.

THE annual dinner of the Indian Medical Service will be held at the Trocadero Restaurant on Wednesday, June 15th, at 7.15 for 7.30 p.m., when Major-General R. W. S. Lyons will take the chair. Tickets and all particulars may be obtained from the joint honorary secretary, Colonel J. J. Pratt, I.M.S. (ret.), 18, Nevern Mansions, Warwick Road, London, S.W.5.

DEATHS IN THE SERVICES.

LIEUT.-COLONEL EDWARD TEMPLE HARRIS, D.S.O., I.M.S., died of peritonitis, on May 24th, at Mayoyo, Burma, aged 49. He was born on April 27th, 1878, the son of the late Dr. A. B. Harris of Falmouth [illegible]'s College, Cambridge, and at the Middlesex [illegible]d as B.A. and B.C. in 1903, and as M.B. in [illegible]After filling the post of house-physician [illegible] he entered the I.M.S. on August 31st, 1903 [illegible] of lieutenant-colonel on February 28th, 1923. [illegible] the recent great war, was thrice mentioned in dispatches, and received the D.S.O. in 1917.

Captain Gautam Kumar, I.M.S., died on April 4th, aged 32. He was born on June 15th, 1894, and educated at the Punjab University, Lahore, where he graduated M.B. and B.S. in 1918. Entering the I.M.S. as a temporary lieutenant on July 23rd, 1918, he received a permanent commission on November 1st, 1920, and became captain on July 23rd, 1921. He served in the latter part of the recent great war.

Medical News.

THE ninety-first annual report, for the year 1926, of the Royal Medical Benevolent Fund is a volume of 200 pages, a large proportion of them, in the nature of things, being given to lists of donors and subscribers. Matter of most general interest will be found in the brief report of the Committee of Management, presented to the annual meeting two months ago, and reported in our issue of April 16th, p. 740. It will be recalled that during the year there was an increase of £1,050 in new subscriptions, and altogether 622 persons were relieved by grants or annuities. The income from subscriptions and donations was £7,250, and from invested property £4,718. The total distribution was £10,770, and the working expenses were £1,367. Discussing the financial position generally the committee expressed the hope that as the result of the organization set up by the British Medical Association, the income of the Fund would increase, and thus enable assistance to be disbursed on a larger scale. Grateful acknowledgement is made to the continued assistance of the Association in collecting subscriptions from its members; these amounted to £1,141 in 1926. Thanks are also tendered to the editors of the *British Medical Journal* and the *Lancet* for their help by publishing monthly reports of the meetings and in other ways.

IN connexion with the approaching Annual Meeting of the British Medical Association in Edinburgh next month it may be well to remind members proposing to attend that the Hotels and Lodgings Committee has taken over all the available rooms in the city. Dr. Drever, the Scottish Medical Secretary, 6, Drumsheugh Gardens, Edinburgh, has undertaken the work of allocation, and members requiring rooms should communicate with him without delay. Very few single rooms are available in hotels, but there are some in boarding houses and hostels, and there are plenty of double rooms. Members proposing to attend the meeting who have made their own arrangements for accommodation are requested to notify Dr. Drever.

THE summer dinner of the Australian and New Zealand Medical Association in England will be held on June 17th at the Piccadilly Hotel. Mr. Joseph Cunning will be in the chair, and Sir John Bland-Sutton, Bt., will be the official guest. Medical visitors are invited to communicate with the honorary secretaries, E. T. C. Milligan and Bedford Russell, 86, Harley Street.

THE annual meeting of the Sheffield Association of the Medical Women's Federation will be held in the Medical Library, the University, Sheffield, on Saturday, June 25th, at 3.45 p.m., when an address will be delivered by Dr. Helen Boyle (Brighton) on manifestations of nervous instability. A cordial invitation is extended to all members of the profession to be present.

THE next meeting of the Biochemical Society will be held in the Biochemical Department, The Museum, Oxford, to-day (Saturday, June 11th) at 3 p.m.

SIR RICHARD T. GLAZEBROOK, K.C.B., F.R.S., formerly Director of the National Physical Laboratory, has been appointed a member of the Advisory Council for Scientific and Industrial Research.

THE General Medical Council has republished the report on the conditions under which medical and dental practitioners registered or legally qualified in their own country may practise abroad. The book first appeared in 1910 and subsequent editions were issued up to 1921. Lists are included of countries in which medical practice is permissible without legal qualifications, and of those where naturalization is an essential requirement. The information given is for the most part of a general nature, but in every case an address is supplied of an official from whom further information may be obtained. The volume, which is obtainable from Messrs. Constable and Co., Ltd. (10, Orange Street, London, W.C.2), at the price of 2s. 6d. (postage extra), will be found very valuable by those who are contemplating medical practice in foreign lands. The Dental Board of the United Kingdom has prepared a memorandum (price 1s., post free) on the procedure to be adopted by those who wish to enter the dental profession, with notes on the costs and prospects. Reference is made to the system of bursaries instituted by the Board, and it is suggested that a considerable increase in the number of dental students is desirable. Further information about these bursaries may be obtained from the Registrar of the Dental Board, 44, Hallam Street, Portland Place, W.1.

AN employment bureau for convalescent patients from tuberculosis has been opened by the Society of Superintendents of Tuberculosis Institutions, with a temporary office at 122, Harley Street, W.1. Lists of vacant posts will be supplied at intervals to members of this society and the Tuberculosis Society.

THE fifth congress of French-speaking pediatrists will be held at Lausanne next September, when the following questions will be discussed: Treatment of paralyses in childhood; vaccine treatment of bronchopneumonia.

THE Accademia dei Lincei of Rome, founded in 1603, has received an annual donation of 4,275 dollars from the Rockefeller Institute for the purchase of scientific periodicals.

A BUST of Emil von Behring was recently unveiled in the hall of honour of Mexico University, of which he had been made a doctor *honoris causa* in 1910.

DURING 1926, 1,614 cases of acute poliomyelitis with 171 deaths, and 6,787 cases of puerperal fever with 1,872 deaths, were notified in Germany.

WE have received a copy of the fourth volume of papers emanating from the Obstetrical and Gynaecological Clinic of Copenhagen University. It consists of a collection of seventeen articles in French, German, English, or Danish, which have been published elsewhere, with an appendix dealing with the statistics of the clinic for the year 1925.

A PAMPHLET describing the natural brine baths of Droitwich can be obtained from Mr. H. Berkeley Hollyer, Baths Offices, Droitwich. A detailed account is given of the various forms of treatment and of the surrounding country, with numerous illustrations.

Letters, Notes, and Answers.

All communications in regard to editorial business should be addressed to ***The EDITOR, British Medical Journal, British Medical Association House, Tavistock Square, W.C.1.***

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the BRITISH MEDICAL JOURNAL alone unless the contrary be stated. Correspondents who wish notice to be taken of their communications should authenticate them with their names, not necessarily for publication.

Authors desiring REPRINTS of their articles published in the BRITISH MEDICAL JOURNAL must communicate with the Financial Secretary and Business Manager, British Medical Association House, Tavistock Square, W.C.1, on receipt of proofs.

All communications with reference to ADVERTISEMENTS, as well as orders for copies of the JOURNAL, should be addressed to the Financial Secretary and Business Manager.

The ***TELEPHONE NUMBERS*** of the British Medical Association and the BRITISH MEDICAL JOURNAL are *MUSEUM 9861, 9862, 9863,* and *9864* (internal exchange, four lines).

The ***TELEGRAPHIC ADDRESSES*** are:

EDITOR of the BRITISH MEDICAL JOURNAL, *Aitiology Westcent, London.*

FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements, etc.), *Articulate Westcent, London.*

MEDICAL SECRETARY, *Medisecra Westcent, London.*

The address of the Irish Office of the British Medical Association is 16, South Frederick Street, Dublin (telegrams: *Bacillus, Dublin*; telephone: 4737 Dublin), and of the Scottish Office, 6, Drumsheugh Gardens, Edinburgh (telegrams: *Associate, Edinburgh*; telephone: 4361 Central).

QUERIES AND ANSWERS.

"T. D." asks for advice in the treatment of a man, aged 62, who, for the past three years, has suffered every three or four weeks from attacks of vomiting, accompanied by profuse perspiration, and lasting from one to six hours. The patient has been examined by a specialist and has been given laxatives, without improvement.

NEURITIS AND ULTRA-VIOLET RAYS.

DR. C. BURGOYNE PASLEY (Perak, F.M.S.) asks for suggestions for the treatment of a woman, aged 40, in whom neuritis developed after exposure to ultra-violet rays. She had resided in the tropics for many years, but underwent two operations while on leave recently in England (tonsillectomy for septic tonsils and [illegible]ulcer). Since her return to the [illegible]mia and general debility. She [illegible]ultra-violet rays, which were increased weekly up to an exposure of six minutes. She always complained of fatigue after the treatment, but her appetite improved somewhat. Early in March she contracted influenza and was ill for a week. Four days after recovery rather severe sciatic pains developed and persisted for two days, and she was then attacked by acute neuritis in both hands. The thenar eminences, thumbs, and index fingers were chiefly affected; the pulp of the terminal phalanges became very tense and painful, and there was moderate pain over the shoulder girdle and posterior aspect of the neck. At the present time (one month after the commencement) the pain is rather less in all regions. Little benefit resulted from drugs, with the exception of local applications of belladonna; a short exposure to ultra-violet light seemed to increase the pain. Dr. Pasley asks whether the neuritis could have been caused by the light treatment, and if it is contraindicated in such a case.

PRECORDIAL PAIN.

"A. O. W." writes in reply to the medical man, resident abroad, whose inquiry appeared on May 14th (p. 903), suggesting that he should wholly abandon the use of tobacco and not expect much benefit for four to six weeks, as it takes that time to eliminate the nicotine. Meanwhile, let him take small doses of calomel—say, 1/5 grain—every night till he gets fairly free motions, and three times a day 5 grains of aspirin of a high quality.

INCOME TAX.

Payment of Bank Interest.

"S. P." paid £82 interest on bank overdraft, and claimed repayment thereon on the ground that the interest was paid out of taxed income. The amount repaid has been reduced by setting off the amount of earned income relief due in respect of £82.

*** The ground for the set-off is presumably that the overdraft was obtained for professional purposes and that the amount of the interest could have been deducted as a professional expense. If that is so the earned relief would have been affected by reduction of the amount of earned income assessed and an appeal would not be advisable.

Obsolescence of Car.

"F. H." has forwarded a copy of the local inspector's figures, from which it appears that in computing the obsolescence allowance he has deducted from the cost of the car (£252) the total amount of wear and tear during the life of the car, instead of

£56, the amount actually allowed for tax purposes under the Finance Act, 1925.

*** Rule 7, applicable to Cases i and ii, Sch. D, of the Income Act, 1918, uses the words "after deducting from that cost the amount of any allowances which have at any time been made in estimating profits or gains as aforesaid on account of the wear and tear . . . ." The inspector's calculations seem clearly inconsistent with the plain meaning of the words "allowances which have . . . been made."

Motor Car Allowance.

"A." replaced his car in December, 1925, by one of the same make and value (£225), being allowed £125 for the old car; the net cost, therefore, was £100, which sum was allowed as an expense of the year 1925–26. For the financial year 1926–27 "A." claimed depreciation allowance for the new car on £225, but the local inspector will allow depreciation on a value of £180 only—that is, on the value (as he reckons it) at April, 1926.

*** This is not, so far as we know, in accordance with the practice in professional or commercial concerns. It is true that the courts have endorsed the practice of taking the value as at the commencement of the year for the wear and tear allowance, but it is usual to ignore fractions of a year. In any case the inspector's figures need revision; even if the new car was bought as early as December 5th there would be only one-third of the year's depreciation to take into account at April 5th, 1926—that is, £15, not £45, and the 1926–27 allowance will be 20 per cent. of £210=£42. If the inspector agrees to this we advise our correspondent to let the technical point go; in the long run the matter will rectify itself automatically on an obsolescence claim when the new car is replaced.

LETTERS, NOTES, ETC.

THE MEDICAL MAN IN PARLIAMENT.

DR. NATHAN RAW writes: In his address to the Chelsea Clinical Society, reported in the BRITISH MEDICAL JOURNAL of June 4th (p. 1024), Dr. Graham Little, M.P., describes the work of the medical group at present in Parliament. It might appear from the report that the present committee was the first of its kind in the House of Commons. I am sure Dr. Little would not wish to convey that impression. In the Parliament of 1918, of which I was a member, we had a committee composed of the medical and University members of Parliament and Lord Dawson from the House of Lords; we met every month during sessions, and many important legislative questions concerning public health were discussed in detail. The committee was composed of Sir Watson Cheyne (chairman), Sir William Whitla, Lord Dawson, Sir Philip Magnus (then member for London University), the late Sir Henry Craik, Colonel Fremantle, Major Molson, Major Farquharson, Dr. McDonald, Captain Walter Elliot, Dr. Murray, and myself. It received numerous deputations on questions concerning the medical profession. It was in close touch with the British Medical Association, and was able to tender advice and guidance which was much appreciated by the Government of the day.

DR. GRAHAM LITTLE has also written in order to remove any misapprehension that may have been caused by the phrase that there are "about two hundred practising lawyers in the House of Commons." What he had intended to convey, he says, is that there are probably that number of persons in the House who are qualified to practise law, though a smaller, but still considerable, number actually do so. His object was to point out that from his own experience he could assert the possibility of combining parliamentary duties with a consulting and hospital practice. "It is," he continues, "obviously more difficult for a general practitioner than for a consultant to serve in Parliament, but I wish to make the definite point that the combination of medical and parliamentary work is possible, and that more opportunities should be given for men in practice to enter Parliament. It will hardly be disputed that a man in practice is more able to gauge the feeling of the profession than one who has no further contact with it."

DANGERS OF HIGH-POWER *X*-RAY APPARATUS.

IN view of the possibilities of accidents occurring to users of the modern types of high-power *x*-ray apparatus, Messrs. Watson and Sons are issuing with each set of apparatus supplied a placard of warning, which it is intended should be hung up in a conspicuous position in a department; it consists of some ten paragraphs, which point out the chief dangers and the methods of avoiding them. These are the dangers, not of *x*-rays themselves, but those arising from the actual electric supply and from the high tension currents, etc.; that there is actual danger to life from such causes is evidenced by the fact that a short time ago a doctor and nurse were both killed instantaneously when making an *x*-ray examination of a patient.

VITAL CAPACITY AND ARTIFICIAL EXERCISES.

DR. HORACE HILL, M.R.C.P., of the R.N. School of Physical Training, Portsmouth, writes to criticize exercises designed to enlarge the thorax artificially by direct force and leverage, and done with the idea that these increase vital capacity and produce physical fitness. A man with a very small vital capacity may, he states, be very fit, and a big chest measurement may be associated with a small vital capacity. Increased pulmonary capacity does not imply a good "wind," power of endurance resistance to disease, or ability to work. A good "wind" depends upon the co-ordination of the heart and lungs, and is best obtained by graduated running in the open air. Unless the circulation carries the oxygen to the tissues, the passage of large volumes of air in and out of the lungs is useless. Enlarging the thorax artificially, while ignoring the physiological processes within it, is comparable with increasing the size of the abdomen to make room for more food, irrespective of the process of digestion; the body cannot be forced in this way to absorb more air or more food. Investigations of the vital capacity are therefore, of little value unless the reaction of the heart to the different states of respiration is tested at the same time. Moreover, the vital capacity varies rapidly, owing to temporary causes, such as nervousness, a meal, or a cold. If the vital capacity is deficient and no lesion can be found, the best treatment is exercise out-of-doors and graduated runs, which cause natural and deep breathing, and train the heart concurrently.

THE TREATMENT OF SMALL-POX.

DR. J. BARCROFT ANDERSON (London) writes: I venture to think many members of the profession would like to be reminded of the information you published on October 11th, 1913 (p. 906) being a report by the Director of the Medical Department at Mauritius upon the results of treating with daily intravenous injections of electrargol about 150 of the worst cases of small-pox selected during an epidemic which attacked 1,500 persons. He wrote: "If cases are treated before the full development of the rash, no matter how close the papules may be, they go no further. Those that have already begun to suppurate dry up. Those that have not yet suppurated do not do so, and those that are not yet papular remain simple maculae and die away. The secondary fever does not appear, and the case takes a favourable turn after the first injection." The dose he recommended was 20 c.cm.

PARALYSIS OF THE CERVICAL SYMPATHETIC COMPLICATING MUMPS.

DR. M. C. TORRANCE (London, E.) writes: Cases of paralysis of the cervical sympathetic are in themselves rare, but its occurrence as a complication of mumps is, I believe, sufficiently rare to warrant recording. On April 4th I attended a girl, aged 5 years, with a six weeks' history of mumps, which began in the right parotid gland. One week after the commencement of the attack she complained of vertical and right parietal headache, and the mother noticed that the patient's right upper eyelid was drooping. On examination I noticed that she had ptosis, exophthalmos, and miosis of the right eye. The orifice of Stenson's duct on the right side was inflamed and remained so until May 14th, when she still had the triad of signs of paralysis of the cervical sympathetic. It would be interesting to hear of any similar case complicating mumps.

HERPES AND VARICELLA.

DR. WILLIAM GALLAUGHER (Brighton) writes: I do not find it so easy to trace the connexion between these two diseases, as Dr. Heard suggests. I have had eight cases of herpes this year and am attending five at present. In each case I have made careful inquiry regarding possible contact with varicella, but have in no case traced any connexion. I have not had a case of varicella for some months. I should say it is of the same order of infectiousness as primary pneumonia.

BEDCLOTHES.

THE "Bed-cloz-tuk" is a device for preventing bedclothes from slipping off the sleeper when in bed. The instrument is fixed by straps, or screwed, to the frame of the bed, so that when not in use it does not interfere with the clothes. By pulling up a small nickel-plat[illegible]o bed the clothes are gripped by rubber strap prevent any tightness and allow with movement and with respiration [illegible] and ingenious. It is sold in four models at 7s. to 8s. the pair, according to whether it is required for children's cots, adults' beds, ship bunks, or settees. The inventor and vendor is Mr. S. H. Bartter, 8, St. James's Road, Kingston-on-Thames.

CZECHOSLOVAKIA.

IN the article on Prague in our issue of May 28th there was a slip which we would like to correct. The present Czechoslovakian Minister of Public Health, who entertained the party of British medical men during their visit to Prague, is Dr. Josef Tisó, a clerical statesman from Slovakia. His predecessor in that office was Mr. Jan Sramek.

CORRECTION.

DRS. ETHEL CASSIE and URSULA COX wish to correct an error in their paper on the microscopical and chemical examination of stools in young children (JOURNAL, May 28th, p. 959). In the table on page 960 it should have been stated that the stools of breast-fed children are 100 per cent. acid—not, as printed, 100 per cent. alkaline.

VACANCIES.

NOTIFICATIONS of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals, will be found at pages 35, 36, 37, 38, 39, 42, and 43 of our advertisement columns, and advertisements as to partnerships, assistantships, and locumtenencies at pages 40 and 41.

A short summary of vacant posts notified in the advertisement columns appears in the *Supplement* at page 239.

A British Medical Association Lecture

ON

THE TREATMENT OF BURNS IN CHILDREN.

GIVEN TO THE ABERDEEN DIVISION, APRIL 21ST, 1927,

BY

JOHN FRASER, *M.C.*, M.D., F.R.C.S.ED.,

REGIUS PROFESSOR OF CLINICAL SURGERY IN THE UNIVERSITY OF EDINBURGH.

"THE child is burned!" I never hear that announcement without a shudder, for it has opened the portals to a long avenue of pain and distress, an avenue that may lead to an age-long disfigurement and too often, by shorter ways, to the tragedy of death. Let us take counsel together about it. Wherein are its dangers? What are its risks? How can disaster be mitigated or avoided?

Some years ago I took the opportunity of investigating one particular aspect of the problem—it was that of mortality; the result of the investigation was disconcerting. In a total of 200 cases of burns affecting children up to the twelfth year the death rate averaged 30 per cent. I know it is a startling figure. It is true that the cases from which the records were culled were hospital cases, and so generally of a serious type; it is, moreover, correct to say that the sufferers were children, and therefore more likely to show a heavy mortality. About these facts there is no dispute, and yet I am distressed when I recall that some few years ago one child in three suffering from a burn of moderate severity perished. I have with intent used the term "some few years ago," because recent improvements in the methods of treatment have done much to lighten the shadow. It is of these improvements and advances that I would speak.

THE MEDICO-LEGAL ASPECT.

The subject has a medico-legal aspect, and, as it is one sometimes forgotten, I refer briefly to it.

The statute book contains a law that it is an offence to leave a child of tender years alone in a room with an open fire. The provision is a wise one, and no doubt it has done much to diminish the incidence of burns: but something more is required, for ways and means of escaping the penalties are not difficult to imagine. Certain hospitals recognize the deficiencies of the existing statute, and have instituted regulations which make all cases of burns admitted to their charge notifiable incidents. The notification is to the police, and they, having made the inquiries they consider necessary, take whatever further steps they deem advisable. Experience shows that this later measure is one of real efficacy, and it is to be hoped that its application may be made universal.

CAUSES.

There are, of course, a multitude of ways in which burns may be caused, but, where children are concerned, it is the pulling over of the pot of hot tea or boiling water, and the accidental ignition of the clothing, which are the principal causes of the disaster. In both instances there is the one common and significant feature that the burn is likely to be of considerable surface extent, without, it may be, any real depth of destruction—a feature with considerable bearing upon the ultimate issue.

There are many other points of significance in this matter of the origin of burns to which I need not allude—the daily press disseminates the knowledge admirably: the danger of flannelette as a garment; the education of the child to avoid fire in any shape or form; the demonstration that, when all is said and done, "it was curiosity that once upon a time killed the cat." These are all very minor matters, it may be, and yet how often a young life has been the price paid for their neglect!

PATHOLOGY.

Textbooks, with the dogmatism that is expected from them, have classified burns into various stages or degrees according to the extent of tissue destruction. Such an arrangement no doubt serves its purpose, but it need not concern us to-day. It is rather of the general facts of pathology that I would speak.

When a burn is sustained, a certain amount of cell disintegration inevitably ensues, and, according to the degree of heat applied, the process varies from complete charring and carbonization to coagulation effects upon the protoplasm of the cell, or it may be to simple reactive phenomena in the cells and blood vessels. This is the significant point—carbonization is not a feature of real importance where the subsequent pathology is concerned. It is certainly an irreparable loss of what may be highly important tissues, but so far as any harmful effects upon the biochemistry of the organism are concerned, the process of destruction has been so complete that the part affected is now an inorganic and inert product, and harmless as far as any dangerous influence is concerned.

It is vastly different, however, with those tissues in which the process of destruction has been less complete. Coagulation of the protoplasm is evidently a process fraught with considerable danger. For a certain period after the injury biochemical activity is in abeyance, but thereafter products of intense toxicity are liberated, which, being absorbed into active circulation, and evidently being peculiarly inimical to the specialized parenchyma cells of the liver, kidney, lymphoid tissue, and the central nervous system, originate a group of serious and distinctive symptoms. These facts have been shown by the experimental work of Willis, Vogt, and other observers, but we are apt to forget them and the influence which they exert in the ultimate clinical picture. I shall have occasion later to allude more fully to the general picture and its relations to clinical features, prognosis, and treatment.

The pathology of a burn is thus something far beyond the local lesion. Widespread chemical changes, many of them imperfectly understood, ensue, and what was at first a local tissue destruction ultimately becomes the picture of a body chemistry distorted and a metabolism deranged.

The ultimate end of the story is characteristic: the body alkalis become depleted; the buffer salts, the last line of defence in so many "tight corners," have yielded up their resources; the sufferer passes in a condition in which the hydrogen-ion content of the body fluids is increased, and the condition we speak of clinically as "acidosis" ensues.

THE CLINICAL PICTURE.

The majority of burns in children are extensive in area and superficial in degree, as one would expect from the rapidly extending flow of steam or boiling water, or the spreading conflagration of the burning garments. A certain measure of shock is always present, and its degree is variable; in some instances it is so severe that a fatal issue is a matter of hours, in other cases it is so slight as to pass unnoticed. Its measure depends upon such various features as the age of the child, the position and extent of the burn, and the psychology of the individual. The dry heat of the flame is associated with a greater measure of shock than the moist heat of the steam or water.

The immediate local effect of a burn is temporarily anaesthetic, but after a few minutes there is intense suffering. The pain is probably relieved by hypnotics, and it would seem that with the passing of the initial shock the most dangerous phase is over, and that the issue, though no doubt a long and a painful process, is not likely to be in doubt as regards life.

For one or two days the optimism appears to be justified, and it may be the case progresses to a favourable issue, but in many instances the progress is otherwise. About the third day the temperature, hitherto keeping within normal limits, or being slightly elevated after the "shock" fall, rises to a level of 101° or 102°. There is an ominous restlessness, the pulse rate quickens, and—most suggestive of all—the breathing alters, at first as shown by an increase in rate, and later as a hyperpnoea from an abnormal stimulus of the respiratory centre. The restlessness passes into delirium, and this in a fatal case is followed by coma. The rapid pulse is a prelude to a developing cardiac weakness, and more general evidences are seen in the slight general cyanosis and the cold extremities.

I imagine there are few of you with experience of burns

£56, the amount actually allowed for tax purposes under the Finance Act, 1925.

*** Rule 7, applicable to Cases i and ii, Sch. D, of the Income Act, 1918, uses the words "*after deducting from that cost the* amount of any allowances which have at any time been made in estimating profits or gains as aforesaid on account of the wear and tear . . . ." The inspector's calculations seem clearly inconsistent with the plain meaning of the words "*allowances which have . . . been made.*"

Motor Car Allowance.

"A." replaced his car in December, 1925, by one of the same make and value (£225), being allowed £125 for the old car; the net cost, therefore, was £100, which sum was allowed as an expense of the year 1925–26. For the financial year 1926–27 "A." claimed depreciation allowance for the new car on £225, but the local inspector will allow depreciation on a value of £180 only—that is, on the value (as he reckons it) at April, 1926.

*** This is not, so far as we know, in accordance with the practice in professional or commercial concerns. It is true that the courts have endorsed the practice of taking the value as at the commencement of the year for the wear and tear allowance, but it is usual to ignore fractions of a year. In any case the inspector's figures need revision; *even if the new car was bought as early as* December 5th there would be only *one-third of the* year's depreciation to take into account at April 5th, 1926—that is, £15, not £45, and the 1926–27 allowance will be 20 per cent. of £210=£42. If the inspector agrees to this we advise our correspondent to let the technical point go; in the long run the matter will rectify itself automatically on an obsolescence claim when the new car is replaced.

LETTERS, NOTES, ETC.

THE MEDICAL MAN IN PARLIAMENT.

DR. NATHAN RAW writes: In his address to the Chelsea Clinical Society, reported in the BRITISH MEDICAL JOURNAL of June 4th (p. 1024), Dr. Graham Little, M.P., describes the work of the medical group at present in Parliament. It might appear from the report that the present committee was the first of its kind in the House of Commons. I am sure Dr. Little would not wish to convey that impression. In the Parliament of 1918, of which I was a member, we had a committee composed of the medical and University members of Parliament and Lord Dawson from the House of Lords; we met every month during sessions, and many important legislative questions concerning public health were discussed in detail. The committee was composed of Sir Watson Cheyne (chairman), Sir William Whitla, Lord Dawson, Sir Philip Magnus (then member for London University), the late Sir Henry Craik, Colonel Fremantle, Major Molson, Major Farquharson, Dr. McDonald, Captain Walter Elliot, Dr. Murray, and myself. It received numerous deputations on questions concerning the medical profession. It was in close touch with the British Medical Association, and was able to tender advice and guidance which was much appreciated by the Government of the day.

DR. GRAHAM LITTLE has also written in order to remove any misapprehension that may have been caused by the phrase that there are "about two hundred practising lawyers in the House of Commons." What he had intended to convey, he says, is that there are probably that number of persons in the House who are qualified to practise law, though a smaller, but still considerable, number actually do so. His object was to point out that from his own experience he could assert the possibility of combining parliamentary duties with a consulting and hospital practice. "It is," he continues, "obviously more difficult for a general practitioner than for a consultant to serve in Parliament, but I wish to make the definite point that the combination of medical and parliamentary work is possible, and that more opportunities should be given for men in practice to enter Parliament. It will hardly be disputed that a man in practice is more able to gauge the feeling of the profession than one who has no further contact with it."

DANGERS OF HIGH-POWER X-RAY APPARATUS.

IN view of the possibilities of accidents occurring to users of the modern types of high-power *x*-ray apparatus, Messrs. Watson and Sons are issuing with each set of apparatus supplied a placard of warning, which it is intended should be hung up in a conspicuous position in a department; it consists of some ten paragraphs, which point out the chief dangers and the methods of avoiding them. These are the dangers, not of *x*-rays themselves, but those arising from the actual electric supply and from the high tension currents, etc.; that there is actual danger to life from such causes is evidenced by the fact that a short time ago a doctor and nurse were both killed instantaneously when making an *x*-ray examination of a patient.

VITAL CAPACITY AND ARTIFICIAL EXERCISES.

DR. HORACE HILL, M.R.C.P., of the R.N. School of Physical Training, Portsmouth, writes to criticize exercises designed to enlarge the thorax artificially by direct force and leverage, and done with the idea that these increase vital capacity and produce physical fitness. A man with a very small vital capacity may, he states, be very fit, and a big chest measurement may be associated with a small vital capacity. Increased pulmonary capacity does not imply a good "wind," power of endurance, resistance to disease, or ability to work. A good "wind" depends upon the co-ordination of the heart and lungs, and is best obtained by graduated running in the open air. Unless the circulation carries the oxygen to the tissues, the passage of large volumes of air in and out of the lungs is useless. Enlarging the thorax artificially, while ignoring the physiological processes within it, is comparable with increasing the size of the abdomen to make room for more food, irrespective of the process of digestion; the body cannot be forced in this way to absorb more air or more food. Investigations of the vital capacity are, therefore, of little value unless the reaction of the heart to the different states of respiration is tested at the same time. Moreover, the vital capacity varies rapidly, owing to temporary causes, such as nervousness, a meal, or a cold. If the vital capacity is deficient and no lesion can be found, the best treatment is exercise out-of-doors and graduated runs, which cause natural and deep breathing, and train the heart concurrently.

THE TREATMENT OF SMALL-POX.

DR. J. BARCROFT ANDERSON (London) writes: I venture to think many members of the profession would like to be reminded of the information you published on October 11th, 1913 (p. 906), being a report by the Director of the Medical Department at Mauritius upon the results of treating with daily intravenous injections of electrargol about 150 of the worst cases of small-pox selected during an epidemic which attacked 1,500 persons. He wrote: "If cases are treated before the full development of the rash, no matter how close the papules may be, they go no further. Those that have already begun to suppurate dry up. Those that have not yet suppurated do not do so, and those that are not yet papular remain simple maculae and die away. The secondary fever does not appear, and the case takes a favourable turn after the first injection." The dose he recommended was 20 c.cm.

PARALYSIS OF THE CERVICAL SYMPATHETIC COMPLICATING MUMPS.

DR. M. C. TORRANCE (London, E.) writes: Cases of paralysis of the cervical sympathetic are in themselves rare, but its occurrence as a complication of mumps is, I believe, sufficiently rare to warrant recording. On April 4th I attended a girl, aged 5 years, with a six weeks' history of mumps, which began in the right parotid gland. One week after the commencement of the attack she complained of vertical and right parietal headache, and the mother noticed that the patient's right upper eyelid was drooping. On examination I noticed that she had ptosis, exophthalmos, and miosis of the right eye. The orifice of Stenson's duct on the right side was inflamed and remained so until May 14th, when she still had the triad of signs of paralysis of the cervical sympathetic. It would be interesting to hear of any similar case complicating mumps.

HERPES AND VARICELLA.

DR. WILLIAM GALLAUGHER (Brighton) writes: I do not find it so easy to trace the connexion between these two diseases, as Dr. Heard suggests. I have had eight cases of herpes this year and am attending five at present. In each case I have made careful inquiry regarding possible contact with varicella, but have in no case traced any connexion. I have not had a case of varicella for some months. I should say it is of the same order of infectiousness as primary pneumonia.

BEDCLOTHES.

THE "Bed-cloz-tuk" is a device for preventing bedclothes from slipping off the sleeper when in bed. The instrument is fixed by straps, or screwed, to the frame of the bed, so that when not in use it does no[t] [i]nterfere with the clothes. By pulling up a small nickel-plated [k]nob the clothes are gripped by rubber pad[s] on the strap prevent any tightness and allow th[e] [c]hest with movement and with respiration. The device is simple and ingenious. It is sold in four models at 7s. to 8s. the pair, according to whether it is required for children's cots, adults' beds, ship bunks, or settees. The inventor and vendor is Mr. S. H. Bartter, 8, St. James's Road, Kingston-on-Thames.

CZECHOSLOVAKIA.

IN the article on Prague in our issue of May 28th there was a slip which we would like to correct. The present Czechoslovakian Minister of Public Health, who entertained the party of British medical men during their visit to Prague, is Dr. Josef Tisó, a clerical statesman from Slovakia. His predecessor in that office was Mr. Jan Sramek.

CORRECTION.

DRS. ETHEL CASSIE and URSULA COX wish to correct an error in their paper on the microscopical and chemical examination of stools in young children (JOURNAL, May 28th, p. 959). In the table on page 960 it should have been stated that the stools of breast-fed children are 100 per cent. acid—not, as printed, 100 per cent. alkaline.

VACANCIES.

NOTIFICATIONS of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals, will be found at pages 35, 36, 37, 38, 39, 42, and 43 of our advertisement columns, and advertisements as to partnerships, assistantships, and locumtenencies at pages 40 and 41.

A short summary of vacant posts notified in the advertisement columns appears in the *Supplement* at page 239.

A British Medical Association Lecture

ON

THE TREATMENT OF BURNS IN CHILDREN.

GIVEN TO THE ABERDEEN DIVISION, APRIL 21ST, 1927,

BY

JOHN FRASER, *M.C.*, M.D., F.R.C.S.ED.,

REGIUS PROFESSOR OF CLINICAL SURGERY IN THE UNIVERSITY OF EDINBURGH.

"THE child is burned!" I never hear that announcement without a shudder, for it has opened the portals to a long avenue of pain and distress, an avenue that may lead to an age-long disfigurement and too often, by shorter ways, to the tragedy of death. Let us take counsel together about it. Wherein are its dangers? What are its risks? How can disaster be mitigated or avoided?

Some years ago I took the opportunity of investigating one particular aspect of the problem—it was that of mortality; the result of the investigation was disconcerting. In a total of 200 cases of burns affecting children up to the twelfth year the death rate averaged 30 per cent. I know it is a startling figure. It is true that the cases from which the records were culled were hospital cases, and so generally of a serious type; it is, moreover, correct to say that the sufferers were children, and therefore more likely to show a heavy mortality. About these facts there is no dispute, and yet I am distressed when I recall that some few years ago one child in three suffering from a burn of moderate severity perished. I have with intent used the term "some few years ago," because recent improvements in the methods of treatment have done much to lighten the shadow. It is of these improvements and advances that I would speak.

THE MEDICO-LEGAL ASPECT.

The subject has a medico-legal aspect, and, as it is one sometimes forgotten, I refer briefly to it.

The statute book contains a law that it is an offence to leave a child of tender years alone in a room with an open fire. The provision is a wise one, and no doubt it has done much to diminish the incidence of burns; but something more is required, for ways and means of escaping the penalties are not difficult to imagine. Certain hospitals recognize the deficiencies of the existing statute, and have instituted regulations which make all cases of burns admitted to their charge notifiable incidents. The notification is to the police, and they, having made the inquiries they consider necessary, take whatever further steps they deem advisable. Experience shows that this later measure is one of real efficacy, and it is to be hoped that its application may be made universal.

CAUSES.

There are, of course, a multitude of ways in which burns may be caused, but, where children are concerned, it is the pulling over of the pot of hot tea or boiling water, and the accidental ignition of the clothing, which are the principal causes of the disaster. In both instances there is the one common and significant feature that the burn is likely to be of considerable surface extent, without, it may be, any real depth of destruction—a feature with considerable bearing upon the ultimate issue.

There are many other points of significance in this matter of the origin of burns to which I need not allude—the daily press disseminates the knowledge admirably: the danger of flannelette as a garment; the education of the child to avoid fire in any shape or form; the demonstration that, when all is said and done, "it was curiosity that once upon a time killed the cat." These are all very minor matters, it may be, and yet how often a young life has been the price paid for their neglect!

PATHOLOGY.

Textbooks, with the dogmatism that is expected from them, have classified burns into various stages or degrees according to the extent of tissue destruction. Such an arrangement no doubt serves its purpose, but it need not concern us to-day. It is rather of the general facts of pathology that I would speak.

When a burn is sustained, a certain amount of cell disintegration inevitably ensues, and, according to the degree of heat applied, the process varies from complete charring and carbonization to coagulation effects upon the protoplasm of the cell, or it may be to simple reactive phenomena in the cells and blood vessels. This is the significant point—carbonization is not a feature of real importance where the subsequent pathology is concerned. It is certainly an irreparable loss of what may be highly important tissues, but so far as any harmful effects upon the biochemistry of the organism are concerned, the process of destruction has been so complete that the part affected is now an inorganic and inert product, and harmless as far as any dangerous influence is concerned.

It is vastly different, however, with those tissues in which the process of destruction has been less complete. Coagulation of the protoplasm is evidently a process fraught with considerable danger. For a certain period after the injury biochemical activity is in abeyance, but thereafter products of intense toxicity are liberated, which, being absorbed into active circulation, and evidently being peculiarly inimical to the specialized parenchyma cells of the liver, kidney, lymphoid tissue, and the central nervous system, originate a group of serious and distinctive symptoms. These facts have been shown by the experimental work of Willis, Vogt, and other observers, but we are apt to forget them and the influence which they exert in the ultimate clinical picture. I shall have occasion later to allude more fully to the general picture and its relations to clinical features, prognosis, and treatment.

The pathology of a burn is thus something far beyond the local lesion. Widespread chemical changes, many of them imperfectly understood, ensue, and what was at first a local tissue destruction ultimately becomes the picture of a body chemistry distorted and a metabolism deranged.

The ultimate end of the story is characteristic: the body alkalis become depleted; the buffer salts, the last line of defence in so many "tight corners," have yielded up their resources; the sufferer passes in a condition in which the hydrogen-ion content of the body fluids is increased, and the condition we speak of clinically as "acidosis" ensues.

THE CLINICAL PICTURE.

The majority of burns in children are extensive in area and superficial in degree, as one would expect from the rapidly extending flow of steam or boiling water, or the spreading conflagration of the burning garments. A certain measure of shock is always present, and its degree is variable; in some instances it is so severe that a fatal issue is a matter of hours, in other cases it is so slight as to pass unnoticed. Its measure depends upon such various features as the age of the child, the position and extent of the burn, and the psychology of the individual. The dry heat of the flame is associated with a greater measure of shock than the moist heat of the steam or water.

The immediate local effect of a burn is temporarily anaesthetic, but after a few minutes there is intense suffering. The pain is probably relieved by hypnotics, and it would seem that with the passing of the initial shock the most dangerous phase is over, and that the issue, though no doubt a long and a painful process, is not likely to be in doubt as regards life.

For one or two days the optimism appears to be justified, and it may be the case progresses to a favourable issue, but in many instances the progress is otherwise. About the third day the temperature, hitherto keeping within normal limits, or being slightly elevated after the "shock" fall, rises to a level of 101° or 102°. There is an ominous restlessness, the pulse rate quickens, and—most suggestive of all—the breathing alters, at first as shown by an increase in rate, and later as a hyperpnoea from an abnormal stimulus of the respiratory centre. The restlessness passes into delirium, and this in a fatal case is followed by coma. The rapid pulse is a prelude to a developing cardiac weakness, and more general evidences are seen in the slight general cyanosis and the cold extremities.

I imagine there are few of you with experience of burns

who have not seen this tragic sequence of events, and the development is all the more distressing because it is unlooked for, so that a favourable prognosis may have been given after the danger of the initial shock had passed away.

THE CORRELATION OF THE PATHOLOGY AND THE CLINICAL FEATURES.

The point in the clinical history peculiarly critical is about the third day, when the temperature rises and signs of intoxication become apparent. An indication has already been given of the explanation of the event, but it is not out of place at this stage to elaborate the reasoning more fully.

It is the existence within the body of tissues in a state of chemical dissolution that is evidently the exciting feature of the disturbance—not an organismal decomposition, but a chemical change, and one, moreover, which results in the production of potent toxic elements. We have yet to learn the true nature of the product or products. It has been suggested that they are closely allied with, if not exactly similar to, histamine or pyridine. Certainly there are many points of similarity between the picture of "histamine shock" and that of the toxic stage of burns. The dangerous character of the toxaemia depends upon its liability to pick out and deteriorate specialized tissues—the liver cells, the delicate cells of the kidney tubules, and the chromaffin tissue of the suprarenals. The striated heart muscle is poisoned and degenerated, and the lymphoid tissue shows points of focal necrosis. It is not difficult to explain the symptoms and signs which distinguish the early stages of the toxic phase—the rise of temperature, the restlessness, the rapid pulse—each has its pathological counterpart, but, underlying all this, there is some more subtle influence which specifically and definitely deranges metabolic processes. I agree that no individual substance has been isolated, but we have a great body of evidence, both biochemical and experimental, which puts its existence beyond doubt, and we have the demonstration of its effects as a vivid clinical experience.

With a deranged metabolism and the imperfect catalysis which necessarily follows, further toxic elements arise. It is at this stage that the body alkalis are called upon—a last line of defence, as we have called it—and for a time it may be that this influence is sufficient to stave off disaster, but a time comes when the reserve is depleted, and when this occurs the body organization breaks down and death ensues.

Such is an outline of the picture in a severe or a neglected case. Fortunately there are ways and means by which the tragedy can be averted, and these we shall now discuss.

TREATMENT.

The inclination to focus attention upon the local lesion is one with which we can sympathize, but our judgement in this respect must not be unbalanced, lest it be the so common error of failing to see the wood for the trees. In every burn there is a general problem overshadowing in its importance the local lesion, because, if death ensues, the reason in the majority of cases is related to the general change; and the further point is true, that the local condition is the focus from which the general disturbance originates. It is apparent, therefore, that any discussion of treatment must be embodied under two heads—(A) the general problem, and (B) the local error.

The General Problem.

Shock is the state which first demands attention. It is ordinary surgical shock, in which the local injury and the psychological element both play their interacting parts. The condition is treated on the usual conventional lines: the body heat is carefully maintained and stimulants are administered; if there is much pain, as there almost certainly will be, a sedative is given, and morphine is the safest and the best. If, in spite of these simple and ready-to-hand measures, blood pressure readings indicate that the shock condition is deepening, *fluid (glucose saline) is given* subcutaneously or by proctoclysis. The degree of shock, however, is rarely sufficiently intense to necessitate anything more than the simplest remedies.

As the shock danger is overcome a general improvement becomes manifest, and now is the opportunity to make what provision is possible against the danger that lies ahead. I have described how, in the toxaemia which to some extent must inevitably occur, special calls are ultimately made upon the body alkali reserve. It is no exaggeration to say that on the response given to this demand the issue of life or death may ultimately depend; it surely behoves us, therefore, to make all possible provision for the reckoning which is bound to come. In other words, from the moment the shock-danger has abated means should be taken to alkalinize the body as completely as possible, to build up reserves of alkali sufficient, and more than sufficient, to meet the demands which will be made.

In alkaline sodium phosphate we have the best therapeutic medium for the purpose in view, and it is introduced into the body by the available routes. It is given orally (20 to 30 grains of the dibasic salt every four hours), and, being less objectionable than sodium bicarbonate, it is taken more readily by children; in a 5 per cent. solution it is given by proctoclysis. The choice falls upon alkaline sodium phosphate because it remains in the body longer than bicarbonate. For some reason the kidneys, the real avenue of its excretion, do not pass it out with the same facility as they do sodium bicarbonate. The reason may be that the alkaline sodium phosphate forms a stronger colloidal combination with the body elements, and particularly with the blood plasma.

In addition to the alkalinization, a sugar reserve is supplied, this being in view of the calls upon the liver glycogen which accompany any deterioration of that organ. The sugar is supplied in the form of glucose, as a 5 per cent. solution, and the various methods of its administration are well known to all of you. Coincident with these various preparations and precautions fluid should, of course, be supplied in abundance, preferably by the bowel and the mouth.

Is there any further precautionary measure which can be taken? One has been suggested, but I cannot speak with conviction as to its value. An attractive possibility lies in the discovery of a means by which the toxic element in circulation could be fixed or otherwise corrected, and it has been suggested that we have such a fixative or corrective in hexamine (urotropine). This drug, when administered in solution by the bowel, is said to have a beneficial action in cases of burns, and it is further stated that the benefit springs from the corrective action of the formalin basis upon the toxic element. I understand that the idea has arisen from the fact that hexamine is occasionally used in this way in the treatment of septic toxaemias.

In these various measures, some of proved value, others empirical, we have the different preventive procedures known to us at present, and it is the duty of everyone to put them into practice when the necessity arises.

In a certain proportion of cases, in spite of all efforts, toxaemia of a severe type will develop. Are there any special means of treatment lying to our hands in this event? The late Dr. Bruce Robertson of Toronto shed some light upon this question, and, though the method may seem too specialized for use in general practice, it demands mention. When it is evident that a severe toxaemia is developing it would seem that a blood transfusion might be of benefit, partly by improving the general condition and partly by counteracting the poison in circulation. The suggestion has often been put into practice, but the results of simple transfusion have been disappointing. It was at this stage that Robertson suggested that exsanguination might be combined with transfusion, and at the present time it is in this measure that we have the only treatment likely to prove efficacious in a toxaemia of real intensity. I do not propose to enter into any detail regarding it, but the principle of its method is that the sufferer is bled in a proportion of 20 c.cm. of blood for each pound of body weight. When sufficient exsanguination has been secured, a transfusion of fresh blood from a suitable donor is given to an amount sufficient to counterbalance the loss already sustained by the exsanguination.

The Local Error.

The local error, as the lesion "visible and seen," would seem to make the most urgent demands upon one's attention, but I hope I have succeeded in showing that it is only one point in a general problem.

We have certain ideals to set before ourselves in the local treatment of a burn, and of course I speak of the recent burn, not of the neglected septic sore—this stands in a class by itself. The ideals are to maintain asepticity of the part, to keep the affected tissues dry, and to "fix" the injured tissues in order, if possible, to prevent the dissemination of toxic products into the general circulation. The most successful local applications will be those which fulfil the above desiderata.

Before discussing the individual methods, however, there is the question of the immediate attention to the burnt area. To avoid suffering and to facilitate examination, a light general anaesthesia may be given. The clothes, if adherent, are removed by soaking the part in a warm sterile solution of 10 per cent. sodium bicarbonate. The way in which blisters are to be dealt with depends upon the choice of the method of local treatment. If a "fixative" or "coagulant" technique is to be followed they should be punctured and the pellicle removed, as a coagulum will not form upon detached epithelium; on the other hand, if such a "protective" technique as the paraffin method is chosen, the blisters are punctured and emptied and the pellicle allowed to remain *in situ*.

The Types of Local Treatment.

It is possible and convenient to group the various types of local treatment under three headings according to the ways in which they exert their individual benefits. Thus there are—

A. Fixation methods, such as the alcohol method, the tannic acid method, and others, all of which are beneficial in so far as they fix the "cooked" tissues and so arrest the production and absorption of the toxin.

B. Biochemical methods—for example, the alkaline treatment—which act by counteracting the toxic substance as it is produced.

C. Protective methods—for example, the paraffin or ambrine methods—which exert their benefits by a mechanical protective influence upon the affected tissues.

Perhaps I ought to say that there is yet a fourth method, that of excision of the burnt area. It has been seriously practised in certain Continental clinics, and it is obvious how completely it ensures the abolition of a toxaemia, but the field for its use is at best a limited one, and, in view of the success which has attended less drastic methods, it need not be considered as a practical possibility.

Permit me briefly to discuss certain individual points of the various methods which are of practical value.

Fixation Methods.

1. *Treatment by Absolute Alcohol.*—This method is undoubtedly one of value. It is obvious how completely it fulfils the ideals of an antiseptic, a desiccant, a fixative. Has it, then, any disadvantages? It has; its rapid evaporation makes a continuous application difficult, and, if a large area is to be treated, the expense is considerable. It finds its greatest value in localized burns of the face, because the scarring is less than by any other type of treatment. When the alcohol method is employed it is essential that the entire affected area be kept constantly moistened with the fluid. A gauze pad several layers thick is laid over the affected surface, and is kept saturated by repeated spraying or by laying a number of capillary drains upon its surface and connecting these with a small central reservoir. The method, of course, necessitates complete confinement to bed and a great deal of attention, but the results in a suitable case are remarkable.

2. *The Picric Acid Method.*—Until recently this was the most popular method of treatment. The composition of the fluid is as follows:

Picric acid	2 drachms.
Absolute alcohol	1½ oz.
Water	To 2 pints.

To obtain the best results the application should be made as a spray or as a paint, frequently repeated, and the part should be exposed to the air in order to hasten evaporation. A thin gauze covering is all that is necessary. Picric acid is a weak antiseptic, but it has certain powers of cell fixation which may inhibit the production of toxaemia. The method is associated with a risk which must never be lost sight of; in extensive burns the absorption may be so great that poisoning effects are produced.

3. *The Aluminium Aniline Method.*—This application has not met with wide recognition in this country; its use is more favoured abroad. A 2 per cent. aluminium acetate in spirit solution is mixed with a 5 per cent. alcoholic solution of methylene blue in a proportion of ten parts of the aluminium solution to one part of the methylene blue. The solution is sprayed upon the affected surface, exposure to the air is encouraged, and only a light gauze dressing is kept in place.

4. *Treatment by Adrenaline.*—Douglas has described promising results from the use of an adrenaline application. A solution of 1 in 10,000 is employed, frequent spray applications are made, and, as in the other methods, exposure to the air is encouraged. Adrenaline has considerable bactericidal and antiseptic value, but in this instance its benefit depends upon its vaso-constrictor influence and the diminished absorption of toxin from the burnt area. Rawdin and Ferguson[1] employ a solution consisting of 1/2 per cent. novocain to each ounce of which is added 10 minims of 1 in 1,000 adrenaline.

5. *The Tannic Acid Treatment.*—Pfeiffer first showed that the toxic extracts from burned tissues are precipitable *in vitro* by mercury bichloride in an acid solution or by phosphotungstic acid. Mercury bichloride was actually used as a therapeutic measure in the treatment of burns by Fauntleroy and Ravogli, but the risks of absorption from a large burned area are too great, and the method has never met with acceptance. Davidson, while investigating phosphotungstic acid, had his attention drawn to the fact that tannic acid has similar properties with fewer disadvantages, and he introduced and elaborated its use in burns. Its value lies in the fact that it precipitates the poisonous substance in burnt tissue and tans the affected area into a resistant and partly insensitive area unlikely to be the site of any septic invasion. The application is made in various ways. After many experiments we have found the most satisfactory to be the spraying of the surface with a freshly prepared 2.5 per cent. watery solution of tannic acid every hour until the tanning is complete, as shown by the deep brown colour of the coagulum. The part is thereafter left exposed to the air, but protected from any gross injury by a sterile gauze covering. If cold is complained of, the part may be placed in an electric light cradle. When the burn is on the face, and particularly in the proximity of the eyes, 5 per cent. tannic acid ointment, made with equal parts of lanoline and vaseline as a basis, may be substituted for the aqueous solution, but the efficiency of the ointment is much less than that of the solution. In a period of time varying from fourteen to twenty days the tanned area separates, to leave a clean granulating surface. The use of tannic acid is a real advance in the treatment of burns, and more than any other method it has reduced the mortality figure.

The Biochemical Method.

Alkaline Treatment.—Many burns do extraordinarily well if treated in a bath of warm sterile water containing 10 per cent. sodium bicarbonate, and, when a small child is severely and extensively burnt, this is a most valuable and efficient method. The child is slung in some kind of hammock arrangement, and provision is made to keep the water at a uniform temperature. If such subtotal immersion is for any reason impossible, or if the burn is small, the application of a light compress soaked in a 10 per cent. watery solution of sodium bicarbonate is soothing and efficacious. The value of the method is based on biochemical data.

Wiener[2] found that the intracellular proteoses demand a faintly acid medium for their full activity, and this activity is checked by exposure to an alkaline medium for any length of time. We have already alluded to certain aspects of the question in speaking of the alkalinization

which is intended to prepare for the oncoming toxaemia, and alkalinization, both general and local, will probably figure in future schemes of burn treatment.

Protective Methods.

The Paraffin Method.—The various methods of treatment hitherto mentioned have acted either as a chemical antidote or as a fixative of cells and their toxins; the value of the paraffin method lies in the protection and mechanical fixation of the part. The original "ambrine," or No. 7 paraffin, is the best application. Its constitution is as follows:

Resorcin	1 part
Eucalyptus oil	2 parts
Olive oil	5 ,,
Soft paraffin	25 ,,
Hard paraffin	67 ,,

The combination melts at 48° C.

There are various ways of making the application. The part may be first brushed over with absolute alcohol, and the surface thoroughly dried by a current of hot air. The burnt area is then covered with the fluid wax, which has previously been brought to the proper temperature in a water-bath. The wax is applied as a spray, or painted on with a sterile brush. Over this a thin layer of sterile cotton-wool is applied, and, when the application has hardened, a further layer of wax is added, followed by an additional layer of wool, and so on until sufficient thickness has been obtained.

Souttar employs a simple and efficacious technique somewhat different from that described above. The part having been prepared with alcohol, strips of ribbon gauze one inch wide are provided. These are passed rapidly through the molten paraffin, held for an instant until the edges begin to whiten, which is the sign that the correct temperature has been reached, and then firmly applied over the affected area, the strips being laid in series edge to edge.

Whichever method is employed, the after-treatment is important. After twenty-four hours, when the application is examined, it is found that the protective covering has been raised in various places by local accumulations of serum; these are punctured with a hot metal point and evacuated. A further layer of paraffin is then added, and the process is repeated when necessary.

If the burn has been in a reasonably aseptic condition a paraffin dressing may remain *in situ* for ten to fourteen days or even longer. Theoretically the original dressing may remain in place until the sloughs separate; actually, reapplications are almost invariably necessary before this aim is achieved.

The After-Treatment.

While the development of granulation tissue is proceeding and healing is advancing, care must be taken to guard against the development of contraction. Its appearance is insidious, and we have yet to perfect a method for its prevention. Much, however, can be done by massage and movement and the wearing of suitable appliances.

As soon as the granulating stage is sufficiently far advanced the raw area is grafted by Thiersch grafts or pedicle grafts, but these are details not within the scope of this lecture.

The surgeon's responsibility does not cease, however, with the application of the graft. The tendency to scarring continues, and a close watch is therefore kept upon the part, and any sign of contraction is combated by such means as massage, exercises, ionization, and cautious *x*-ray therapy.

I confess it was with a measure of trepidation that I chose the subject of this lecture. I dare say there are some of you who may have thought the subject a somewhat sterile one; I trust I have succeeded in dispelling any such opinion. A severe burn in a young child is one of life's catastrophes, and you and I can do much to avert disaster if we are alive to the possibilities.

MINERS' NYSTAGMUS.

BY
FREELAND FERGUS, M.D., LL.D.,
HONORARY SURGEON, EYE INFIRMARY, GLASGOW.

IN the BRITISH MEDICAL JOURNAL of April 30th (p. 80 there appeared a report of a contribution by Dr. Halda to a discussion on miners' nystagmus, which discussion h now been going on in the *Transactions* of the Institution Mining Engineers for over a year, and to which, throu the courtesy of that institution, I contributed the opeiii paper; on several other occasions I had the privilege making other remarks, the last being a reply which made to Dr. Haldane's lecture in Glasgow on April 23r 1927. I will now state concisely my reasons for rejecti Dr. Haldane's defective light theory, or at any rate f holding it as not proven.

Several points demand discussion, such as the fa that the introduction of electric light has, in many pit aggravated the disease. Then, again, his theory do not seem to explain why the disease is more frequent seen at certain periods of the year than at others. Neith Dr. Haldane nor the Nystagmus Committee takes a notice of the paroxysmal nature of the disease. A patie who has had the disease, but who has to all appearanc recovered, may keep well for days or even weeks, but m then suddenly have a very severe attack. If a man h apparently recovered and is living above ground, and not exposed again to the defective lighting, he should c Dr. Haldane's supposition keep well. As a matter of fa he is far from being immune and will certainly have subs quent attacks, some of them as severe as the first. Th liability to relapse may last for years; I am now seein cases that have been victims of the disease for five or si years. They have not been exposed to defective lightin during the whole of that time, and some of them ar suffering quite acutely from the disease.

Lastly, why is nystagmus not present in all pits lit b oil safety-lamps? I am informed by a gentleman of th highest authority, Mr. G. L. Kerr, that he knows of si pits in the area in which he works in which the oil safety lamp is used, but there is no nystagmus. Is that to b explained on the supposition that the oil safety-lamps i these pits are at all times in excellent condition and tha in the others they are habitually unsatisfactory? Dr Haldane's theory does not seem to offer any explanation.

Nor has any feasible explanation been given as to wh there should be, as one of the symptoms, rotational move ments of the eyes. Neither Dr. Haldane nor any of hi colleagues on the Nystagmus Committee has said anythin about the nerve centres which must be irritated or dis turbed before the rotation takes place. In neither of th reports is there any mention of disturbance of nerve centres nor is there any discussion as to the centres likely t be involved. The two reports are extremely disappointing I except from that criticism, however, the work done b Dr. Haldane on the chemical side. That must be taken a authoritative. The oblique muscles must be involved in an rotational action, such as that which takes place in miners nystagmus; their action is simply secondary to the superio and inferior recti muscles. In ordinary life they hav almost no independent action of their own, yet, whe there is nystagmus, the movements are chiefly rotational To me it is absolutely unthinkable that the muscles are in violent action without any disturbance of the centre supplying the nerves to these muscles, and yet the Com mittee does not make any suggestions as to the nuclei and centres involved in miners' nystagmus. Because such matters are left out I think that when there is anothe investigation a member of the committee should be a neurologist of the highest standing.

Another feature that must be taken into account is tha the disease seems to appear in epidemic form. Some year it is very frequent, in others it is not nearly so common That is a matter which, in my opinion, should be con sidered by persons who are in the habit of dealing wit vital statistics. The twelve months preceding the coa dispute were extremely bad; so far as the area in whic

I work was concerned cases were very numerous. But for the first six months after the dispute was over there were scarcely any new cases, and my work as referee during that period was almost entirely the re-examination of miners who had been certified long before the dispute took place, some of them years before it. Now the absence of fresh cases is open to at least two explanations. In the first place we may, when the cases were very numerous, have been passing through an epidemic, or, on the other hand, the long absence from work may have been physically beneficial to the men and brought on a kind of immunity.

In the two reports issued by the Nystagmus Committee no mention is made of the chief symptom of the disease—namely, great disturbance of the innervation of the heart. I cannot help thinking that had the investigation been made by medical officers of health such a condition would have almost at once attracted their attention. Pulse rates up to 120 are by no means uncommon. The only reference I can find to the cardiac condition is contained in a report by the late Dr. Rivers, subsidiary to the first report. At page 13 of the first report the following words are to be found: "The modern teaching is that the disease is either a general fatigue of the whole oculo-motor system or a general neurosis with special local manifestations in the oculo-motor apparatus." Certainly cardiac instability is much more frequently present than rotation of the eyeballs. Why has no mention of that been made in the above definition? On page 20 of the second report we find a grouping of cases relative to compensation. The principal symptom, according to this classification, is oscillation, and we have at line 17 from the top the following words: "Oscillation is regarded as the primary sign; lid spasm, head tremor, objective giddiness, and photophobia as secondary signs." Here again there is no mention of the quick and generally weak and irregular pulse. So, too, at the foot of page 17, we have a paragraph entitled "Severity of attack on certification." This concerns the examination of 128 miners—a number inadequate to justify any conclusion. But the classification is again based on oscillation and no reference is made to any irregularity of the pulse. The failure to take notice of a condition which is one of the most prominent symptoms of the disease does not inspire me with any confidence in the thoroughness of the examinations made. Dr. Haldane's work as a chemist is, of course, of the most authoritative kind, and I take it as such, but he is not a clinician, and I do not think the clinical side of the case has been at all well done.

The late Dr. John Brownlee, certainly a man very authoritative on vital statistics, and who himself was a widely experienced and well trained clinician, said to me when we happened to meet in London on March 1st, that he had been looking into my views on miners' nystagmus and had come to the conclusion that I was probably right in saying that it was not a disease due to the illuminants used.

For the above reasons I think that a reinvestigation is necessary. The disease may be due to a toxin or to a micro-organism, but the very fact that the number of new cases recorded in one year differs very much from the number of cases recorded in another year, the differences being wide, seems to indicate that the disease is not due to illumination, for then the number of new cases occurring each year would be nearly constant.

Similarly, it is to be remarked that very little attention is given in either of the reports to the practically invariable presence of hemeralopia and nyctalopia in association with miners' nystagmus. The committee seems to have fixed its attention on one thing only—the presence or absence of eye movements—and has not even noticed what is to me the most important symptom of all, cardiac irregularity.

One or two cases have been seen in men working at the screens, not underground at all. That seems a very significant fact. I do not think the committee is in any way responsible for missing out such cases. I have not seen any myself, and I have seen many hundreds of patients with miners' nystagmus; but the few that have occurred tend to confirm my conviction that the disease is not due to defective illumination. I am an agnostic as regards the origin of miners' nystagmus, except that I feel confident that it has not been proved to be due to defective illumination. On the contrary, the evidence which I personally have got points very strongly in the opposite direction. Unfortunately, no *post-mortem* examinations have been obtained; they might have yielded good results. Pathologists and medical officers of health and epidemiologists have done a great deal to unravel many diseases, and, in consideration of the serious economic position to which the disease has given rise in the coal-mining industry of Great Britain, I think further investigations are urgently required, neurologists, public health authorities, and pathologists being called in to assist.

I shall conclude by giving a few illustrative cases.

W. B., aged 37, miner, seen on March 31st, 1927, had no trouble with his eyes till three or four days before he left off work (on March 2nd). He had been working entirely with the electric light for the preceding five years and had no symptoms whatever of the disease before he used electric light.

W. D., drawer, seen on March 31st, 1927, had worked with the oil safety-lamp till 1916, and then with the electric from 1919 till 1920. In 1925 he first suffered from symptoms of nystagmus and that very severely. For some years before the attack he had used nothing but electric light.

A. McK., aged 37, brusher, seen on April 27th, 1927. When he first suffered from the disease he was in a pit lit with electricity, and had been in it for several years; the disease began on March 19th, 1926. He was compensated till September 16th, 1926, but was unable to get work till March 29th, 1927, and then he obtained employment in a pit which was particularly well lit with electricity. In this case there does not seem to be any history of his ever having worked in a pit lit by oil safety-lamps.

J. B., aged 21, brusher, seen on May 2nd, 1927, had been in coal pits for seven years. He began in one pit which was chiefly lit by electricity, but in which oil safety-lamps were sometimes used. He was for four and a half years in that pit and then moved to another lit entirely by electricity. He was in this second pit for fully three years, and first noticed symptoms six weeks ago. He saw objects rotating in front of him.

R. C., a miner, aged 47, seen on May 2nd, 1927. The symptoms in this case began not more than a year ago. He is quite clear on that point. He has been using nothing but electric light in the pit for three years. He expressed the opinion that electric light is extremely bad for eyesight.

J. C., a stone miner, aged 42, seen on May 5th, 1927, had been in various pits. I will distinguish each pit by a numeral. He began mining at the age of 14 in pit number 1, a naked-light pit. He was there a year and then removed to pit number 2, which, at that time, was worked with oil safety-lamps. He was there for about twelve or thirteen years, and during that time had no trouble with his sight. Then he removed to pit number 3, where he was only twelve months, still using the oil safety-lamp and still without any trouble. Then he went to pit number 4, where he used sometimes an electric head lamp, and on other occasions an oil safety-lamp. The oil safety-lamp was carried only as a protection; he used the electric light for working. He was in this pit for about thirteen years and, for the first time, while working with the cap electric lamp, felt some symptoms of the disease. Then, about two years ago, he went to pit number 5, entirely lit with electricity. He states quite distinctly that for coal mining the oil safety-lamp is much superior to the electric because it gives less strain to the eyes.

T. G., a miner, aged 55, seen on May 5th, 1927, began in a naked-light pit at the early age of 12. He was only two years there when he went to another pit, where he remained for nineteen or twenty years. This second pit was entirely lit by oil safety-lamps, and he had no nystagmus nor had any trouble of the eyes; two and a half years ago he went to a pit lit throughout by electric light. After being some time in this pit he felt his eyes and head beginning to trouble him. There was intense pain, chiefly at the back of the head, but frontal pain also. The important points in this case are that the patient was for twenty years in an oil safety-lamp pit without having the disease, but had it after he had been three years in an electrically lit pit.

T. K., aged 44, brusher, seen on May 5th, 1927, felt no inconvenience with his eyesight down to the beginning of the strike of 1921. Shortly after resuming work he for the first time noticed defects. The first symptom was that everything appeared in motion at the bottom of the pit. The lamp at that time was the oil safety-lamp. He took a lump sum of money in 1922. He does not seem to have begun work till a considerable time afterwards, and first began with work above ground. Ultimately he went to an electrically lit pit, and was only able to stand the bright light for five weeks, when he again became severely ill with the disease and had once more to apply to the certifying surgeon.

These are only a very few cases taken within the last six weeks. I have records of many hundreds of cases, but the above will, in the meantime, I think, answer my purpose, which is to show that electric light is by no means a preventive of miners' nystagmus. Not infrequently it is found that men who have worked for many years with a moderate amount of nystagmus in pits lit by oil safety-lamps have been attacked very severely by the disease on

the introduction of electric light. There is no gainsaying these facts. No doubt we may be told that it is because the best type of electric lamp has not yet been procured, and the coal owners may be called upon to face further great expense on that head. I think that, before any such demand is made of them, there should be a much more thorough investigation into the cause of the disease, which investigation would include a well organized collective investigation throughout the entire coal-fields of the United Kingdom. Such a research ought unquestionably to be in the hands of persons competent to deal with vital statistics and with public health.

MINERS' NYSTAGMUS.

NOTES FROM THE SOUTH WALES COAL-FIELD.

BY

FREDERICK ROBSON, M.D.,

CARDIFF.

MINERS' nystagmus continues to be a cause of much concern, both to workmen as a disabling event in the life of underground workers, and to their employers as an *economic factor. It is one that exhibits itself in different* ratios among men employed in different places, and it has some connexion with coal and the variations in gaseous contamination of mine air. This fact is brought into prominence by the high incidence of the disease in parts of the coal-fields where a kind of coal that has much volatile matter in its composition is worked. The fact that more cases take origin in certain coal seams than in others should induce authorities to inquire into the composition of those kinds of coal in which highest and lowest incidence of nystagmus is observed. The number of men affected with the disease in each pit or district chosen should be ascertained, and compared with the total number of men employed in these areas. The introduction of electric lamps has not brought about the much desired result; it has not diminished the number of cases, and such lamps may have actually induced the condition in cases that were quiescent, or aggravated it in others that were evident both to the man and the medical examiner. The time has more than arrived when other possible causes should be inquired into. These are pit environments and the condition of the air at the coal face, the gob, the workings, the main roads, and the return airways. In all of these situations cases of nystagmus arise. In some pits, possibly in most, the collier is the workman who suffers most, but there are seams in which cases of nystagmus arise in parts distant from the face, and show an equal percentage with face workers. In a series of years ending in 1926, out of thirty-two protracted cases contracted in South Wales, 75 per cent. occurred in miners, and 25 per cent. in four other grades. Doctors practising in different parts of the coal-fields differ in their conclusions as to whether the disease is or is not present, and are often at variance with medical referees in this respect. Clinically miners' nystagmus is a very complex condition to diagnose, and to determine whether it has ceased so that the man is fit for work. It is no easy matter either for him or for his doctor to decide this point.

The evidence, so far as it goes, indicates that some pathological entity exists around which many signs and symptoms revolve; in the schedule of disease (III) of the Workmen's Compensation Act, 1925 (No. 17), it is defined as "The disease known as Miners' Nystagmus, whether occurring in miners or others and whether the symptom of oscillation of the eyeballs be present or not." This definition makes for trouble in diagnosing the disease on its kaleidoscopic manifestations; hence the differences in medical opinion expressed at examinations. The disease may manifest the presence of oscillation of the eye, and this movement definitely determines its existence, but subjective symptoms, such as headache, giddiness, and loss of orientation, may be all that is complained of—that is to say, subjective symptoms without objective signs may be the chief determining characteristic; and this is how the fallacy in diagnosis arises.

In the South Wales and Monmouthshire coal-field in 1925, among 157,473 men of all grades above and below ground, there were 621 cases of nystagmus, or nearly 0.4 per cent. In 1926, for 153,738 men so employed (for five months only, owing to the cessation of work in the coal-fields), the number of cases of nystagmus was 263. The estimated number for twelve months would have been 631, so that in 1926 more cases might have been expected to arise than in 1925, though the number employed was fewer by 3,735.

A study of the results of the examination of cases by colliery doctors in this coal-field reveals many facts of interest, such as high blood pressure, chronic nephritis with albuminuria, rapid heart, constant headache in some area of the head, the occurrence of the disease after head injuries not found before such injuries, and many years' standing of some cases, with no evidence of amelioration of signs or symptoms though the men had not resumed pit work. Resumption of work and renewed failure on many occasions is frequently reported. Men at the pit bottom with good light may suffer; one-eyed men get nystagmus. Chief among the signs accompanying oscillation may be photophobia, blepharospasm, conjunctivitis; head tremors alone may replace eye tremors and completely disable the man so suffering. Central vision varies in different cases, and many other defects may accompany the involuntary oscillation of eyeballs which is the chief determining characteristic.

No Act of Parliament can define the degree, range, or definition of the disease—for example, head tremors, which may be the only evidence of the disease, are not included in the schedule of signs. No special inquiry, as far as I know, has been made as to the association of labyrinthine nystagmus with miners' nystagmus, yet it may complicate the pure forms of oscillation. The man as a whole should be examined, as the eye is simply the outpost of the commonwealth of his being. Hereditary predisposition does not, I think, count in the genesis of the disease, but a poor nervous endowment does. The history of men who resume work underground and fail repeatedly should be investigated, since some proclivity to the disease may be disclosed in the man, such as the red corpuscle ratio, or it may turn out that the causative agent is something in the environment. It would be in the men's interest to have all boys examined at 14 years of age, before beginning pit work, so that the weedy ones might be induced to give up the idea of engaging in an occupation so hazardous as mining. Physical robustness should be the standard of acceptance. Some doctors consider that this condition is a form of neurosis from the beginning, and that the special nervous symptoms are secondary. In all neuroses there must be some physiological nutritional derangement of function of brain cells, and such defects may arise where the air is less life-supporting than the healthy stimulus of light and fresh air in the open spaces above ground.

The average duration of cases of nystagmus is uncertain, and cannot be defined in terms of months or years. Some colliery doctors declare that when nystagmus (oscillation of eyes) has once definitely arisen it will reappear on resumption of work underground. There is a good deal to be said for this opinion—that is to say, "once nystagmus always nystagmus." Again, in some instances men have resumed light work on the surface and failed, although they had not restarted work underground. This fact indicated to my mind that the disturbance to the central nervous system is well defined and likely to be permanent.

Some men do resume work underground and do not again suffer from nystagmus. Such men have on my advice been placed on the fresh-air side of the pit, where there is comparative freedom from deleterious environment, but the same safety-lamps are used. Considering the absence of correlative evidence of doctors' reports on nystagmus it is urged that some definite and exhaustive syllabus of its range, including both signs and symptoms, should be published by the Government advisers relative to mines and the diseases arising therein.

Incidentally it may be mentioned that beat-knee has become almost as prominent in some pits as nystagmus, and is steadily growing in ratio to men employed underground. The opinion of medical men of equal experience and ability

varies within considerable limits as to the diagnosis of nystagmus; County Court judges are also much perturbed in such cases. All these facts indicate that some authoritative definition of the disease and its many phases is urgently required.

Whatever opinion is held as to the causation of nystagmus the pathological entity round which this complex revolves is involuntary oscillation of eyeballs, and that, in my opinion, cannot be explained away on a psychological basis. To the elucidation of the cause of this defect in the minor the expert coal chemist should add his quota to that of the doctor.

ACUTE PANCREATITIS: A METHOD OF TREATMENT.

BY

R. G. HENDERSON, M.A., M.B., F.R.C.S.ED.,

BOURNEMOUTH.

THE careful study of acute pancreatitis by Mr. Hamilton Bailey in the JOURNAL of February 26th (p. 367) recalls my own experience. The chief difficulty in diagnosis arises from not having the condition in mind. I remember well my first experience of this. When engaged with out-patients, I was asked by the house-surgeon to see a case of acute intestinal obstruction just admitted for immediate operation. After examination I came to the conclusion that the case was not intestinal obstruction, but what exactly it was I could not say with certainty. I concluded, however, that the symptoms and signs indicated peritonitis limited to the lesser sac, and that the most likely cause of this was probably a small perforation of the posterior surface of the stomach, although there was no history of previous stomach trouble. When the abdomen was opened the patches of fat necrosis at once proclaimed the pancreatic lesion, which, till then, I had not taken into account.

Surgical writers, of course, advise drainage of the pancreas, and the various anatomical routes of approach to the organ are described. But they are reticent as to what should be done with the pancreas. Many writers appear to imply that it is enough if a drain is introduced down to the pancreas, and the inflammatory exudate present in the lesser peritoneal sac thereby permitted to escape, with precautions against infection of the general peritoneal cavity. But surely that is not enough. The condition of a patient with really acute pancreatitis is desperate; the gland is acutely congested, swollen, and tense, and appears on the high road to total gangrene. The patient is profoundly toxaemic, slowly dying from the absorption of poisons from his pancreas. The obvious indications for treatment are to stop absorption, to relieve tension, and to allow free exit of inflammatory products so that any part of the gland not already dead may have the best chance of recovery. General treatment of a supporting nature will, of course, not be neglected. It appears to me that the only way to fulfil those indications is freely to open up and drain the gland itself. That this can be done with safety and immediate benefit to the patient the following case—the first on which I used the method—will show:

I was called to see a man, aged 30, about 7 o'clock one morning in the early part of 1915. He was healthy, not fat, but given to bouts of drinking, and he had been indulging a few days before I saw him. It was a typical case of acute pancreatitis, and I sent him at once into the Oldham Royal Infirmary, and four hours later, about five hours from the commencement of his illness, opened the abdomen by a median incision. The pancreas was reached through the gastro-colic omentum. It was greatly swollen and deep purple, almost black in colour. My problem was to lay open the glandular tissue freely so as to drain the whole organ efficiently, and to do this without causing undue haemorrhage or infecting the general peritoneal cavity. I snipped through the peritoneum on the anterior surface of the pancreas, and pushed a finger well down to the middle of the pancreas, and then worked the finger from one end of the swollen gland. I then allowing it to some extent to follow the path of least resistance, so that eventually there was a kind of trench along the anterior surface of the gland, extending from head to tail, and rather nearer the upper than the lower border so as to avoid injury to the duct of Wirzung. From this longitudinal trench short lateral branches or diverticula were made at intervals by pushing the finger into the gland tissue, especially at places where it felt softened. The bleeding was free but not excessive, and was easily checked by a temporary gauze pack in the trench. A wide-bore rubber tube was passed down to the pancreas, the gastro-colic omentum snugly adjusted round it with the aid of a stitch, the upper part of the tube wrapped in gauze to shut off the general peritoneal cavity, and the abdominal wall closed above and below the tube. The wound was dressed daily and the pancreas gently mopped through the tube. The patient made good progress without interruption. Five days after operation two sloughs of pancreatic tissue were discharged, each about the size of a walnut. The tube was kept in for about a week and thereafter the wound healed soundly and quickly. No sugar appeared in the urine during his stay in hospital. Some months later he joined the army, served in France, and continued in good health.

I have used this method, or assisted colleagues in using it, in three cases of acute pancreatitis, all of whom recovered. The number is small but quite sufficient to demonstrate that the inflamed pancreas can be freely opened up and drained, not only with safety, but with immediate and lasting benefit to the patient.

AN OPERATION FOR HALLUX RIGIDUS.

BY

W. A. COCHRANE, F.R.C.S.ED.,

ASSISTANT SURGEON, THE ROYAL INFIRMARY, EDINBURGH.

DISSATISFACTION with the functional end-results of the ordinary operations for hallux rigidus has induced me to try what has proved to be a simple, but effective, substitute. When one of the ordinary operations, such as removal of a wedge of bone limiting dorsiflexion or the trimming away of a portion of the head of the metatarsal, is practised, an elastic resistance to dorsiflexion still remains. This is due to the shortened and contracted structures on the plantar aspect of the metatarso-phalangeal joint, particularly the plantar fibres of the lateral ligaments. The spasm of the intrinsic muscles of the great toe, whose tendons are inserted into the base of the proximal phalanx, is also a factor. These features, together with the organization of blood clot and the development of painful adhesions, are responsible for poor functional end-results.

The difficulty being largely and very often wholly extra-articular, it seemed illogical to attack the bony and cartilaginous elements of the joint. An operation was planned, therefore, to divide the shortened structures on the plantar aspect of the joint.

In the first case chosen there was no osteo-arthritis of the metatarso-phalangeal joint, but the rigidity could not be corrected by forced manipulation under the anaesthetic. It seemed eminently suitable, therefore, for what might be termed this intermediate type of operation. A longitudinal incision, one inch long, with its centre over the level of the articulation, was made in the mid-line over the plantar aspect of the metatarso-phalangeal joint of the great toe. The sheath of the flexor longus hallucis was incised in the line of the skin incision and the tendon hooked aside. A strong, narrow-bladed knife was then passed into the joint to divide the capsule on its plantar aspect, along with the tendons of the small muscles attached to the base of the proximal phalanx. The plantar fibres of the lateral ligaments were also divided. Dorsiflexion, full and free, was obtained. The toe was bandaged in moderate dorsiflexion. Active and passive movements were begun on the third day. Full function was present by the time the stitches were removed and full weight-bearing begun on that day.

The operation has been done in a series of twelve cases with equally gratifying results. The patients have all expressed themselves as satisfied and there have been no relapses. Osteo-arthritis was present in three, and a wedge of bone, base upwards, was removed from the dorsal aspect of the joint. An elastic resistance to full dorsiflexion still remained, but disappeared at once on the performance of the small additional procedure here described.

Most cases of hallux rigidus occur in slender feet with a relatively long great toe, and attention must, therefore,

be paid to the fitting of a suitable shoe that is not too short. Measures must also be taken for the treatment of a tendency to faulty statics and flat-foot, which it is usual to find associated with hallux rigidus, and which are concerned in its causation.

TWO CASES OF SPONTANEOUS RUPTURE OF THE HEART.

BY

C. J. THOMAS, M.R.C.S., L.R.C.P.,
ASSISTANT MEDICAL OFFICER,
AND
S. R. TATTERSALL, M.R.C.S., L.R.C.P.,
PATHOLOGIST,
COUNTY MENTAL HOSPITAL, LANCASTER.

IN a recent article on rupture of the heart, J. Strickland Goodall and H. B. Weir,[1] after analysing a series of cases, express the opinion that a physical pathological state, and not some emotional strain, is the prime causal factor. The two cases here described corroborate that conclusion, and in addition appear to be of interest, in one case because of the unusual site of rupture, and in the other on account of the unusual nature of the pathological cause of the rupture.

CASE I.

A woman, aged 53, was admitted in April, 1918, in a restless, excitable condition. In April, 1920, she had crossed paralysis of the right arm and left leg, with slight facial paresis, but consciousness was not lost. She was up and about in December, 1920, and continued to lead a quiet, aimless life, doing no work of any description. There was evidence of myocardial insufficiency shown by slight oedema of the lower extremities. On April 11th, 1922, the patient was taken ill at 8.40 a.m. (one hour after rising), and expired almost immediately. There was a suspicion that the patient had recently visited the lavatory, but we were unable to get any definite evidence on this point. It is to be noted that in Goodall and Weir's series of eighteen cases three occurred in connexion with visits to the lavatory, the strain of defaecation apparently being the effort which precipitated the final catastrophe.

The autopsy revealed signs of passive congestion in all the viscera. The oedema of the legs was still noticeable. The cranial cavity contained an excess of cerebro-spinal fluid, ventricles were dilated and the convolutions wasted. The pia mater was thickened, and there was an area [illegible] motor area of the left cerebral hemisphere. [illegible]stended by blood and blood clot. The rig[illegible]d showed a large tear posteriorly, about 4 [illegible] of the rent were ragged, irregular, and [illegible] muscle was soft and flabby, and there was considerable sclerosis of the coronary arteries. The heart weighed 266 grams.

CASE II.

A man, aged 62, a shoemaker by trade, was admitted in June, 1906, in a state of noisy excitement with acute hallucinations of sight and hearing. For many years prior to his death he had been in a state of progressive dementia, confused, idle, solitary, and unresponsive. He was known to be the subject of cardio-vascular degeneration. His death occurred suddenly one morning, whilst still in bed.

The autopsy revealed a large flabby heart, weighing 420 grams, the pericardium again being distended with blood and blood clot. The left ventricle was found to be ruptured posteriorly, the external opening of the rupture being about 2 cm. ong. It resembled a clean-cut surgical incision, and ran in a direction parallel with the muscular fibres. Further inspection of the site of the lesions showed that the ventricular wall was diffusely affected by a gummatous condition. The tear on the inner surface of the ventricle showed ragged edges, and the haemorrhage had extended laterally for some distance in the wall of the ventricle. On one side it had pursued a U-shaped course, and had almost penetrated again into the ventricular cavity. The coronary arteries were sclerosed, and in the aorta were patches of atheroma sharply limited to the points of origin of the intercostal arteries. A feature of interest was that the thymus had not undergone its usual atrophic changes, but extended downwards as far as the base of the heart.

It is possible that rupture of the heart is a more common mode of death in cases of cardio-vascular degeneration than is commonly believed. Neither of the deaths here recorded could be said to be unexpected, and it is certain that in the absence of permission for a *post-mortem* examination no difficulty in assigning a cause of death would have been experienced, and the ruptures would have been undiscovered. The strain in Case i was at the most a physiological one, and in Case ii the entire absence of any strain is noteworthy. Auricular rupture is uncommon, for while it is conceivable that degenerative processes may occur in the wall of any of the chambers of the heart, it is obvious that the walls of the ventricles will be more likely to rupture on account of the extra strain to which they are subject. Quain,[2] in a summary of cases collected from various sources, gives the frequency of sites of rupture as: left ventricle 76 times, right ventricle 13 times, right auricle 7 times, left auricle twice; the interventricular septum was ruptured in four cases. Elleaume,[3] quoted by Quain, found the right auricle ruptured in 3 out of 55 cases. The age of both our cases was over 50, as it was in over 80 per cent. of the recorded cases. Syphilis of the heart is well known as a cause of sudden death, and cases of rupture reported by Dandridge and Nalty are mentioned by Osler.[4] Stott and Blair,[5] in a recent article, note the apparent predominance of the female sex in cases of ruptured heart. From an examination of the records of a large number of cases it would seem that the reverse is true, although not to the extent of the predominance of male cases recorded by Strickland Goodall and Weir (16 male to 2 female).

We are indebted to the medical superintendent of the hospital, Dr. R. P. Sephton, for permission to record the foregoing cases.

SPONTANEOUS RUPTURE OF THE RIGHT VENTRICLE OF THE HEART.

BY

B. LLEWELYN HODGE, M.R.C.S., L.R.C.P.,
HOUSE-PHYSICIAN, ESSEX COUNTY HOSPITAL, COLCHESTER.

THE following case shows several unusual features, which are worthy of record.

An unmarried woman, aged 57, was admitted to the Essex County Hospital, Colchester, complaining of a swelling of the abdomen, first noticed one month before admission. It was causing slight abdominal discomfort, and there was some oedema of the legs, most marked at the end of the day. There had been no nausea or vomiting, and no jaundice. She had dyspnoea on exertion, but no cough, no difficulty of micturition, and no cramping pains in the legs. She had been losing weight for the previous two months. Menstruation had ceased at the age of 48, but there had been a slight "show" four months previously.

There was impairment of the percussion note at the bases of both lungs, presumably due to the liver being pushed up by the abdominal contents; otherwise, the lungs appeared healthy. The apex beat was in the fourth space, 2¾ inches from the mid-sternal line. The impulse was poor, and the area of cardiac dullness was not increased. The first sound at the apex was very faint and prolonged; the other sounds were faint, but no murmurs were heard. There was some oedema of the legs and lower part of the back.

The abdomen was distended, and the umbilicus protuberant. There was marked shifting dullness in the flanks; a fluid thrill was perceived on palpation. In the right hypochondrium there was a mass the size of a foetal head, hard, fixed, and apparently smooth. In the left hypochondrium there was a smaller mass, the size of a Tangerine orange, which could be pushed easily towards the mid-line. The liver was apparently pushed up by the abdominal contents. The spleen and kidneys were not palpable. The uterus was small, senile, and freely movable, and the cervix was healthy. The mass on the right side was free from the uterus; that on the left, from its mobility, was thought to be a subperitoneal fibroid. The urine was normal chemically and microscopically, and the Wassermann reaction was negative. A diagnosis of right-sided ovarian cyst, with free ascitic fluid, was made, and a pedunculated fibroid was suspected. About two hours before the contemplated operation, after the usual routine preparation of the abdomen, the patient complained of sudden nausea and slight precordial pain. She tried to sit up in bed, but collapsed. Her face was pale and clammy, but there was no cyanosis; she became unconscious in about five minutes, and died about ten minutes after the onset of the symptoms.

At the necropsy death was found to have been due to a rupture of the right ventricle. The lungs were compressed, and congested at the bases; there was no evidence of pulmonary embolism. The pericardium was full of blood. The heart was small, and was coated with bright yellow fat, which also covered the aorta. At the apex of the right ventricle there was a definite perforation, the size of a small knife-stab. The musculature of the heart generally, was extremely thin, that of the apex of the right ventricle practically consisting of the endothelial lining of the heart, with an outer covering of about three-quarters of an inch of fat. The walls of the auricles were exceptionally thin. The aortic valves showed slight atheromatous changes, but the other valves were normal.

The peritoneum contained a large quantity of dirty green fluid with flakes of free lymph; there were no miliary deposits. The

intestines were collapsed. The liver showed a state of mild cirrhosis; on microscopical examination there was found an increase of fibrous tissue around the bile ducts, with partially obliterating endarteritis of the vessels. The spleen, uterus, and appendages were normal, but the kidneys were slightly granular. There was a typical broad-ligament cyst on the right side, of irregular shape; it passed across the bladder, with a small protuberance causing the apparently separate mass on the left side. On section it proved to be an innocent multilocular growth, with papillary proliferations.

This case has several features of interest. The muscular effort which ruptured the heart must have been very slight, as the patient was lying in bed. She was by no means a nervous woman, and was perfectly willing to be operated on for her condition. The right ventricle is said to be affected in only one quarter of these rare cases of rupture of the heart, the left ventricle being the usual chamber involved. The slight degree of precordial pain, and the comparatively long duration of life after rupture, due, no doubt, to its small size, add interest to a very unusual case.

My thanks are due to Dr. S. W. Curl for permission to publish this case, and for his help in compiling these notes.

TREATMENT OF RINGWORM BY THALLIUM ACETATE.

BY

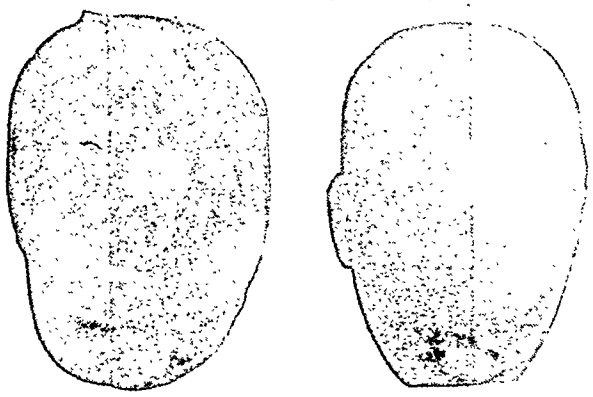
STANLEY J. FIRTH, M.B., CH.B.VICT., M.R.C.S., L.R.C.P.,

ASSISTANT MEDICAL OFFICER, WITHINGTON HOSPITALS, WEST DIDSBURY, MANCHESTER.

SINCE reading the report in the BRITISH MEDICAL JOURNAL of February 19th (p. 329), I have taken the opportunity of investigating the treatment of ringworm of the scalp in children at the Withington Hospitals, by the internal administration of thallium acetate. The cases were taken at random among children up to 5 years of age, no consideration being given to the extent or duration of the disease.

In all cases the urine was ascertained to be free from *albumin*, *albuminuria* being a contraindication to the use of the drug, and in all cases a positive spore test had been returned before treatment.

The dose of thallium acetate given was 1/8 grain per 2½ lb. of body weight, irrespective of age. The drug is easily soluble, and was made up in sweetened water and administered in a single dose. No constitutional symptoms were observed after the administration of the drug, nor yet in the case of one child who received a second administration six weeks later. No local treatment was applied to the scalp, but the head was covered to prevent loose hairs being a source of infection to other children. The shedding of hair commenced between the fourteenth and sixteenth days. The hair could then easily be pulled out without causing any discomfort, and it also came off in the caps. The shedding was in every successful case complete in from three to six days. The very short stumps were found to be loose, and were readily extracted by application of adhesive plaster for a few minutes. The action of the drug was entirely selective to the hair of the scalp.



In all cases a roughness of the extensor aspects of the forearms and of the outer side of the legs was observed about the tenth day after the administration. After the shedding of the hair dermatitis of the scalp occurred in several cases, but yielded to treatment by zinc ointment in the course of a few days. The new hair commenced to grow almost immediately.

Case 1.—A boy, aged 4 years, presented several patches of ringworm of the scalp; he had been treated for over six months by various local applications. The child's weight was 2 st. 2 lb. 12 oz., so 1.7 grains of thallium acetate was given on March 22nd. Epilation commenced on April 6th (sixteen days after) and was complete in six days. He has now quite a fair crop of hair, and spore tests from different parts of the scalp are negative.

Case 2.—A child, aged 1 year 8 months, weighing 1 st. 8 lb. 2 oz., was given 1.23 grains of thallium acetate; the shedding of hair began on the fifteenth day and was complete in five days.

Case 3.—A child, aged 2 years and 8 months, weighing 1 st. 13 lb. 6 oz., was given 1.52 grains of thallium acetate; the shedding of hair began on the fifteenth day and was complete in five days.

In Cases 4, 5, 6, and 7 shedding of the hair commenced on the fourteenth day and was complete in three days. Photographs of one of these cases are reproduced; the age of the patient was 3 years and 6 months, and he weighed 2 st. 3 lb. 4 oz. A dose of 1.74 grains of thallium acetate was given on April 23rd, and the

shedding of the hair commenced on May 6th. In Case 8 the child, aged 2 years and 4 months, and weighing 1 st. 12 lb., was given 1.5 grains of thallium acetate. The shedding of hair commenced on the sixteenth day and was complete in six days.

Out of the first ten cases two were unsatisfactory; one was a failure for which I cannot account, as shedding of the hair occurred only very slightly, and the other was unfortunately given an underdose, and shedding of the hair was only partial.

The results of these few cases suggest that there is wide scope for the use of thallium acetate, especially in children under the age of 3, where *x*-ray epilation is inadvisable.

I have to thank Dr. Gibson, the visiting dermatologist, for his interest and help in these cases, and also Dr. Gamble, the medical officer, for permission to report them.

[The reader is referred to a paper on this subject by Professor W. E. Dixon, communicated to the Section of Dermatology of the Royal Society of Medicine on March 17th, and published in the current (June) number of the *Proceedings* of the Society (p. 1197). An annotation of this paper appeared in the JOURNAL of March 26th at page 581.]

CARDIAC FAILURE ASSOCIATED WITH NEW GROWTH IN THE CHEST.

BY

G. HAIG PRINGLE, M.R.C.S., L.R.C.P.,

HOUSE-PHYSICIAN, ROYAL HANTS COUNTY HOSPITAL.

THE following case has interesting features and seems worth recording, as the presence of mitral stenosis, together with a new growth in the chest causing acute symptoms simultaneously, must be exceedingly rare.

The patient, a man aged 41, gave a history of becoming easily fatigued for twelve months, and swelling of the legs and arms for four months. He stated that the oedema in the right arm had always been greater in amount than that in the left.

On admission he was very dyspnoeic and cyanosed. He was coughing up a fair quantity of sputum, which was slightly tinged with blood. There was a considerable amount of oedema—of both legs, the scrotum, and both arms (of which the right was much more swollen than the left). The other signs of cardiac failure present included enlargement of the liver and spleen, a small amount of fluid in the abdomen, and congestion at the bases of both lungs. The urine had a specific gravity of 1020, and contained both albumin and blood.

The physical signs in the chest may be summarized as follows: The heart was enlarged, the right border being half an inch to the right of the sternal margin and the left two inches outside the nipple line. At the mitral valve there was a localized presystolic and a soft systolic murmur. The aortic and pulmonary sounds were normal. It was also noticed that the right apex was less resonant to percussion than the left, and that at this side the breath sounds were distinctly weaker. Enlarged superficial veins were present on the right side of the chest.

The conclusions were that the patient was suffering from cardiac failure due to mitral stenosis, and that there was something in the neighbourhood of the right apex which was partially obstructing the innominate vein. An *x*-ray photograph of the chest was not taken until a later date owing to the gravity of the symptoms.

The cardiac condition was treated by the usual measures; these included rest in bed, venesection, Southey's tubes and incisions into the right arm, and the administration of Nativelle's digitaline and diuretin. After twelve days' treatment there was a marked improvement in all his symptoms, but the oedema of the right arm persisted.

At this stage an *x*-ray photograph of his chest was taken, and Dr. F. C. Jagger made the following report: "There is a rather dense shadow under the right sterno-clavicular joint, which has the appearance of a new growth."

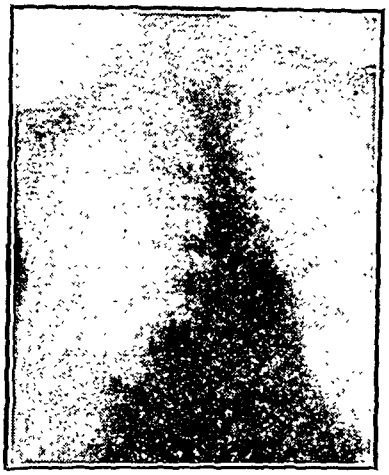


FIG. 1.—Showing the tumour at the right apex.

The patient is now feeling perfectly fit. His mitral condition appears to be well compensated, and there are no physical signs of a tumour in the chest. Further, the

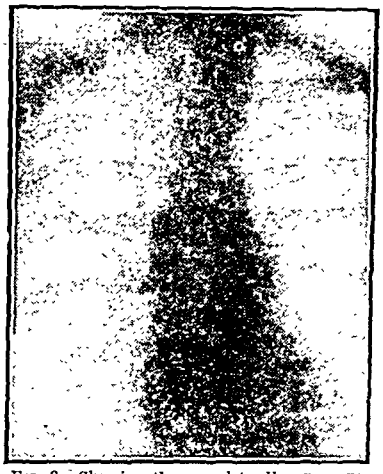

FIG. 2.—Showing the complete disappearance of the tumour after treatment.

Wassermann reaction was negative. It seemed probable, therefore, that the tumour was of the nature of a lympho-sarcoma.

A course of *x*-ray treatment was instituted. Twelve B-pastille doses were given in all, six to the front of the chest and six to the back, in the neighbourhood of the tumour. Under this treatment the tumour soon began to show signs of shrinkage, and the oedema of the right arm gradually disappeared.

x-ray photograph shows that the tumour has completely disappeared, although a secondary deposit of lympho-sarcoma may occur later on.

I am indebted to Dr. G. A. Tullis for permission to publish this case, and my thanks are due also to Dr. Jagger for kindly reproducing the *x*-ray photographs.

Memoranda:

MEDICAL, SURGICAL, OBSTETRICAL.

ACUTE LOBAR PNEUMONIA: DEATH IN NINE AND A HALF HOURS.

THE following case is worthy of record, in that the whole course of the illness, from the initial rigor until death, lasted only nine and a half hours.

Mrs. *T.*, aged *90*, was taken ill and had a severe rigor about 2 p.m. one day during snowy weather. She had been up and about as usual during the morning. She was put to bed and given hot drinks, and some few hours later her relatives found difficulty in wakening her. When I saw her at 5.15 p.m. she was very drowsy and only muttered when spoken to. The pupils were equal and reacted to light. There was no sign of paralysis in any limbs. When she coughed she brought up the typical blood-stained, "rusty" sputum of pneumonia. The base of the left lung was dull on percussion and the breathing was definitely tubular in character. Few adventitious sounds were present. The temperature was 105° F. and the pulse was 120.

I saw her again at 9.30 p.m. when she was quite unconscious, and I verified the diagnosis of lobar pneumonia by further examination. There were no signs of any cerebral lesion. The temperature had fallen to 103° F., but the pulse rate had increased to above 130 with some irregularity. The patient died at 11.30 p.m.

She had been a very healthy old woman considering her great age, but during the last few years had had several fairly severe attacks of acute bronchitis from which she recovered well. During the last twelve months she required no medical attention.

It is of interest to note that the onset was not of the insidious type usually associated with the aged; the rapid course of the illness indicated that the resistance to the infection was practically *nil*.

Manchester. RICHARD I. POSTON, M.D.

INTESTINAL OBSTRUCTION DUE TO TORSION OF THE MESENTERY.

THE following details of a case of intestinal obstruction caused by mesenteric twisting seem to be worthy of record, since such torsion must be a very rare cause of obstruction.

A male Hindu, aged 28, was admitted to the Monghyr Sadr Hospital for acute intestinal obstruction, which had lasted five days; his condition was almost hopeless. The tongue was dry and brown, the breath very foul, the eyes were sunken, the abdomen was distended and tympanitic, and the pulse was feeble. (Lejars aptly described this condition as stercoraemia.) He had faecal vomiting, and gave a history of absolute constipation for five days, not even flatus having passed. Enemas had been given without result. It was decided to operate at once; a rectal injection of ten ounces of glucose solution was given and was retained.

After a preliminary morphine and atropine injection and lavage of the stomach the abdomen was opened under general anaesthesia. The first glimpse of the coils of the small intestine which came into view was very striking; they were deep purple in colour and were beginning to lose their glistening appearance. Some coils escaped from the wound, a few more were pulled out and covered with hot towels. The peritoneal fluid was foul-smelling. The pelvic colon and caecum were not distended, and, from the pre-gangrenous state of the whole of the small intestine, I suspected some mesenteric abnormality. After enlarging the wound and pulling out some more coils of small intestine the mesentery came into view and was clearly seen to be twisted on itself from right to left. More of the small intestine was eviscerated, and I was able to untwist the mesentery just over one turn. There was still another complete twist, but further progress was checked by a loop of the ileum being firmly held down to the posterior abdominal wall above the level of the caecum. Owing to its depth and the bad light, I could not see what was binding down the ileum, but it felt like a twisted cord, as thick as a thumb. While investigating this area gently the gangrenous gut at the seat of constriction perforated, and foul faecal fluid began to pour out of the gut into the right flank. A piece of gauze was pressed down upon it, and a pair of intestinal clamps was immediately applied; the faecal matter was then removed. Excision of any or of the whole length of the gut was out of the question owing to the bad light, the state of the gut, and the condition of the patient. A stab wound was made through the right flank, another pair of clamps was passed through this and placed alongside the first one, which was then removed. This clamp served also to keep open a passage for drainage. Through a small opening in a loop of jejunum a medium diameter rubber drainage tube was passed and fixed by two purse-string sutures. The loop was fixed to the upper part of the wound, the rest of which was closed quickly. Gentle lavage of the jejunum was tried after the patient had been returned to bed, but with only temporary success, the patient dying later. This procedure could hardly have been expected to succeed, but if the patient's condition had improved after drainage another attempt might have been undertaken next day to resect the ileum.

I have found no mention of this condition in any of the standard books on surgery by British authors; thrombosis and embolism of the mesenteric vessels and tumours at the root of the mesentery are described, but not torsion. So far I have only been able to find a description of a similar case by Pierre Delbet, who describes the condition as "Occlusion intestinale par torsion de la totalité de l'intestin grêle et de son mésentère" in the *Bulletin et Mémoires de la Société de Chirurgie*, 1920.

Delbet was more fortunate with his case, for he was able to free the lower loop of the ileum from the posterior abdominal wall by eviscerating and untwisting the whole of the small intestine. My further progress in that direction was checked by this anchorage, so that neither complete evisceration nor complete untwisting could be performed. As no *post-mortem* examination was allowed the cause of this anchorage still remains a mystery. Delbet's description of a peritoneal fold and another loop holding the ileum down is rather unintelligible, and I should be glad to be enlightened by anyone who has had experience of such a case. The direction of this twist, both in Delbet's case and in mine, seems to have been from right to left, so that the gut had to be untwisted from left to right.

DISSECTION OF TONSILS.

THE great majority of tonsils can be completely removed by the inverted guillotine method. There is, however, a comparatively small proportion which cannot be satisfactorily removed by this method and must be dissected out by knife, scissors, etc. This can often be done under local anaesthesia, but there are cases which, for one reason or another, require a general anaesthetic. In these cases considerable difficulty often arises from interference with respiration, haemorrhage, etc., and it is for such cases that the method here described offers a comparatively simple and safe means of treatment.

The patient is anaesthetized in the usual way and an intratracheal flexible metal catheter is introduced through the larynx and chloroform anaesthesia maintained automatically by the patient himself. (A No. 16 catheter is used for adults and a No. 12 for children.) A Doyen's gag is introduced and the lower pharynx packed with gauze. A broad tongue depressor is passed back to the pharyngeal wall and depresses and keeps in position both the tongue and the gauze packing. This gives an excellent view and approach to the tonsil fossae.

It is now a simple matter to dissect the tonsils out of their beds and efficiently control and arrest haemorrhage. The use of a suction apparatus, for the removal of blood from the throat, facilitates the operation. There is no anxiety about respiration. The free airway through the intratracheal tube lessens congestion, and bleeding points can be secured and tied off at leisure.

I believe this to be a "new" technique, for, although I have used intratracheal chloroform for many years for nasal and throat operations, I have only recently tried it in cases of tonsillectomy, and I do not remember having seen it described elsewhere.

W. S. KERR, F.R.C.S.ED.,
Honorary Aural Surgeon, the Royal Infirmary, Sheffield.

BLOOD TRANSFUSION IN HAEMORRHAGIC DISEASE OF THE NEWBORN.

THE following case affords another illustration of the value of immediate injection of whole blood in arresting melaena neonatorum.

A female infant born on April 5th, 1927, at 4 p.m., after an easy and normal delivery without intervention, was cyanosed, but after clearing the throat of mucus it cried lustily and breathing and colour were soon quite normal. It weighed 6 lb. 2 oz.

At 8 o'clock the following morning (6th) it vomited some clotted blood and passed a small black stool; otherwise it appeared quite normal. I saw the child at 10 a.m., and except for the above symptoms there were no other signs of internal bleeding. I ordered 1 minim of adrenaline in a teaspoonful of water to be given hourly for three doses.

At 1.30 p.m. the nurse telephoned me to say that the child was looking very ill and had passed a copious haemorrhagic stool and also vomited a large quantity of blood. I saw the child at 1.45 p.m., when it seemed entirely collapsed and *in extremis*; while I was looking at it it passed a further haemorrhagic stool, almost bright red in colour, and the condition seemed hopeless. I immediately withdrew 25 c.cm. of blood from the mother's vein at the bend of the elbow and injected this into the gluteal muscle of the child, which was put back in its cot and surrounded by hot-water bottles. The effect was immediate and striking. No further vomiting occurred, and except for the passage of a little clotted blood in a stool, passed six hours after the transfusion, no further bleeding took place. The child was twenty-two hours old when the injection was given. Further progress was uneventful; it gained 1 ounce the first week and 8 ounces the second week, and became quite normal.

London, W.2. M. GOLDING, L.R.C.S.I., D.P.H.

Reports of Societies.

ROYAL SOCIETY OF MEDICINE.

SUMMER MEETING OF SECTIONS OF LARYNGOLOGY AND OTOLOGY.

THE summer meeting of the Sections of Laryngology and Otology of the Royal Society of Medicine was held on June 9th to 11th. The laryngological sessions were presided over by Dr. ANDREW WYLIE, and the otological by Dr. DAN MCKENZIE.

Relation of Nasal Polypi to Inflammation of the Accessory Sinuses.

Mr. T. B. LAYTON brought forward this subject for discussion, premising that he had been keenly disappointed with the traditional treatment of simply pulling out the polypi. He had never found this primitive method curative, unless in the case of a single polypus rising beneath the middle turbinal. There was a difference of opinion as to whether polypi ever existed unless there was some underlying disease in the sinuses. When polypi were present without underlying disease of accessory sinuses they were in the large airways, and appeared to him to be a hypertrophy to compensate for the extra calibre of such airways; this type of polypus was best left alone. In most cases the disease underlying the polypi was an inflammation of accessory sinuses. Pus was found among polypi in three circumstances: (1) muco-pus mixed with polypi, the muco-pus being secreted in the nose, thorough cleansing of which would prevent return; (2) pus in small quantity in a sinus, the site of a chronic catarrhal suppuration, the pus in most cases leaking down into the sinus from the nose, so that it was not a true suppurative sinusitis; (3) cases in which a chronic suppuration might be added to a catarrhal inflammation. Nasal polypi might be associated with catarrhal inflammation in the ethmoid and the maxillary sinus. It was not his opinion that acute catarrhal sinusitis ever became acute suppurative sinusitis; the latter was not accompanied by swelling of the mucous membrane, but was associated with extensive hyperaemia. When a sinus was the seat of acute suppuration it was not his practice to open it. Assuming these statements to be correct, what were the best lines of treatment? All the mucous membrane involved in the catarrh must be cleared away. Commonly the ethmoid was involved, and his practice now was to attempt by external incision to remove the whole ethmoid. This avoided the dangerous olfactory nerve area and the cribriform plate.

In the course of discussion Dr. W. S. SYME agreed that the present treatment of nasal polypi was unsatisfactory; he thought that in every case of multiple polypi in the nose there was antral as well as ethmoid disease. His routine, therefore, had been to open the ethmoid. He did not agree with Mr. Layton's sharp line of demarcation between catarrhal and suppurative disease, though in one case the catarrhal element, and another the suppurative might be predominant. Mr. SCOTT RIDOUT also dissented from the view that the catarrhal and the suppurative conditions were separate entities. He believed that the external operation was not done often enough for the disease under discussion. Mr. J. S. FRASER did not feel justified in opening the antral mucosa in this disease, as in several cases he had found it healthy. He did not differentiate rigidly between chronic catarrh and chronic suppuration. A good indication as to whether, in a given case, the antrum should be operated upon was obtained by proof-puncturing the antrum and washing it out. If after clearing the nose the fluid returned freely and readily one might conclude that the antrum was not full of polypi. If force were needed to send fluid through the syringe it was a good indication for doing the radical operation. Mr. F. B. GILHESPY favoured a somewhat long incision through which the external operation, if necessary, should be done. Dr. SUGARA (Buenos Aires) classified polypi into those originating in the sinuses—chiefly maxillary—those which were simple, and those associated with osteitis of the ethmoid. Recurring polypi demanded radical operation.

Chronic Middle-ear Deafness.

In the Otological Section the chief subject for discussion was progressive middle-ear deafness. Dr. G. SCOTT WILLIAMSON brought forward an analysis of data acquired from a study of 51 out-patients at the Central London Throat, Nose, and Ear Hospital suffering from chronic deafness of the type commonly known as "chronic middle-ear catarrh"; only idiopathic deafness was included. The patients were subjected to a thorough examination of the cardiac, respiratory, digestive, urinary, neuro-muscular, genital, and haemopoietic systems. Out of the 51 cases 7 were found to present signs of established disease—namely, mitral disease of the heart (3 cases), Graves's disease (3 cases), tuberculosis (1 case). The tests on the remaining 44 showed with one exception (the cardio-respiratory balance) the patients to be within the normal of average people at their age limits. All the patients showed a decided tendency to tachycardia, and had easily disturbed cardio-respiratory balance. His conclusion from these cases was that the history of the deafness began at puberty or earlier, and he suggested that the marked dullness and apathy of many of these persons were due to their deafness, or at least their low auditory acuity while at school. Another positive fact noted was that in each of the cases the patient had a peculiar aspect depending upon the size and shape of the nose (pinchbeck). The 51 cases included only 5 males, but Dr. Williamson did not regard this as representing any real sex incidence of the complaint. The male, being under greater compulsion to adapt himself, probably ignored his deafness, and, having a larger choice of occupation, selected employment not dependent on auditory acuity. He believed this deafness to be, not a mere accident during the course of life, but a condition with a specific etiology somewhere in childhood. It was not associated with any disease, nor due to local sepsis, but it might be associated with some constitutions or diatheses. Mr. E. HORACE RICHARDS followed with an analysis of the hearing of this same series of patients. His general conclusion was that the characteristics of the whole group were those of deafness of the mixed type, in most cases to a high degree, with a peripheral contraction of the tone limits.

Dr. DAN MCKENZIE gave a clinical review of 748 cases, unselected except that the deafness had got beyond the stage of mildness. He classified them as follows:

Chronic dry catarrh of middle ear	288
Cicatricial changes secondary to healed suppuration	80
Active suppuration	136
Otosclerosis	206

In 38 cases there seemed to be a combination of suppuration, healed or active, with catarrh or otosclerosis. In most cases tinnitus was the earliest symptom. Generally speaking, it preceded deafness by months, sometimes by years; in other cases the two conditions appeared simultaneously. After describing the results of the tuning-fork tests, he said that his figures supported the orthodox teaching that in progressive middle-ear deafness the hearing for deep tones through the air was reduced relatively to the hearing for middle and moderately high tones. With regard to the physical examination, he believed that the condition of the membrana tympani—its colour, texture, and situation, together with the mobility or immobility of the malleus handle, as tested by Siegle's speculum—was no indication of the presence or absence of deafness. His cases manifested five points in common, though varying somewhat in their incidence: (1) tinnitus, frequently composite; (2) progressive deafness; (3) increased bone conduction; (4) variable upper tone limit; (5) a negative Rinne. The fact that this symptom group was common to all the varieties surely indicated that, whatever might be the primary pathological change that initiated the process, there must be some physical factor, also common to all the groups and varieties, that induced the syndrome. It would also seem that once this physical factor or secondary change, whatever it might be, was set going, it would continue to progress by its own inherent tendency, and independently of its initial cause, until its progress came to a standstill. He thought the inner wall of the tympanum might be the seat of the physical factor of which they were in search. It remained to account for two phenomena which recalled the nerve mechanism of the cochlea—namely the tinnitis and the not infrequent diminution of bone conduction. He thought that even such apparently cochlear phenomena as these might be referred to the middle ear and if, as seemed plausible, the fixation of the fenestral structures—whether by bone, as in otosclerosis, or by scar tissue, as in suppuration and the dry catarrhs—might be credited with the power of causing tinnitus by altering intra-labyrinthine fluid pressure in some way, it was possible to refer all the phenomena to the middle ear, and particularly to the inner wall. This argument, he added, did not exclude the real occurrence of genuine cochlear changes, and cochlear deafness, as a result of the permanent withdrawal of normal cochlear stimuli attendant upon serious middle ear deafness—changes which, it was known, did undoubtedly occur.

Mr. G. J. JENKINS declared himself unable to recognize pathologically or clinically, the condition known as "progressive middle-ear deafness," sometimes described as "chronic middle-ear deafness," or even termed "dry middle-ear catarrh." The terminology, in his opinion, was wrong and misleading. They were all familiar with the textbook description of the disease under this name, with the detailed accounts of the active local treatment and general management of the patient. The pathology was in most books purely speculative. The symptoms and signs were usually roughly and indefinitely indicated, and so far as they went, were the same as an imperfectly described otosclerosis syndrome. He believed that if a complete modern examination had been made in these cases on which this terminology was founded, the diagnosis would have been one of otosclerosis. In his opinion, pure middle-ear changes, including fixation of the stapes, would give only pure obstruction signs, and if any symptoms such as internal-ear deafness or those specially associated with otosclerosis were present the labyrinth should then be regarded as affected. He had not known progressive middle-ear deafness, in the sense implied in the title of this discussion, that could be attributed to middle-ear changes only.

In the course of some further discussion, Mr. NORMAN BARNETT thought there could be no question that there was a distinct entity in chronic middle-ear deafness. The cases could be divided into those secondary to a long antecedent suppuration of the middle ear, those with a distinct focus of infection, such as septic tonsils or a septic condition of the nasopharynx, and those in which there was some obstructive lesion, such as a pronounced deflection of the nasal septum. Mr. J. S. FRASER thought the best classification of these cases of chronic deafness was into normal and abnormal tympanic membranes. If one had a case of chronic deafness which gave the usual tuning-fork results with perfectly normal drumheads one might be sure of otosclerosis, no matter whether the flamingo tinge was present or not. In most cases in which there were abnormal drumheads there was no progressive middle-ear deafness. If tinnitus was a marked feature, if there was a hereditary history, if the catheter resulted in no improvement in hearing, and if deafness was increasing, he thought the case might be regarded as otosclerosis, in spite of the abnormality of the tympanic membrane. Sir J. DUNDAS-GRANT had a bias in favour of the idea that many of the cases of chronic or progressive middle-ear trouble were secondary to the narrowing or catarrhal thickening of the walls of the Eustachian tube.

Mr. SOMERVILLE HASTINGS was surprised at the proportion of otosclerosis in Dr. McKenzie's cases. In his experience what he would call otosclerosis was exceedingly rare. Cases ordinarily called otosclerosis really began as sepsis in some region of the nose and throat at some stage in life; he believed that a great many cases of chronic progressive deafness began in very early life. It was difficult to distinguish between the cases in which the process went on whatever was done, and those in which the process could be stayed. The thing to do was to make a careful examination for sepsis and treat it when found. It would not be found in all cases, but in a sufficient proportion to make

that line of treatment worth while. Mr. HERBERT TILLEY said that Dr. McKenzie had spoken of tinnitus as being a cochlear symptom. How did he explain those very desperate cases in which patients had tended to suicide in order to get rid of their "noises," and in whom the auditory nerve had been completely divided within the skull, and yet the tinnitus continued? He also felt that if terminology was important, so was pronunciation. It should be "ti-nī'-tus," not "tin'itus." Dr. McKENZIE recalled an occasion at a Section meeting of the British Medical Association when Sir StClair Thomson, who was in the chair, introduced the opener of the discussion by saying that he would tell them whether it was "ti-nī'-tus" or "tin'itus," whereupon the opener began, "Gentlemen, the subject of my remarks is 'ti-nē'-tus'"!

A medical man who had been a patient, introduced by Mr. Norman Barnett, also spoke. He said that he had noticed deafness as a student when using the stethoscope, and it became worse. Four years ago an operation on turbinates was done, with improvement for a time. In September, 1925, the left ear became completely deaf, and he was advised to give up practice, as nothing could be done for his hearing. An examination in December, 1925, showed a marked deflection of the nasal septum with an adhesive remnant of the right middle turbinate. There were buried septic tonsils and retracted and inflamed tympanic membranes. Submucous resection of cartilage and bone of nasal septum, which was found to be fractured, was done, diseased and adherent turbinates removed, and ultra-violet rays, general and localized for throat, were administered. Sub[illegible] with ionization over mastoid and .. the Eustachian catheter and the tympanum with hot iodine, camphor, and carbolic vapour was carried out. On testing in February and March, 1926, there was improvement for all tests, and hearing for conversation and whispered voice was practically normal. Since then there had been further improvement, and he was now able to carry out all professional examinations with ease. He added that in the country village where he practised there were thirty people who were deaf, and of these he had treated eighteen, on the line of treatment he had himself undergone, with success in every case.

Other Papers and Exhibits.

Among other papers read in the course of the sessions was one by Mr. DOUGLAS GUTHRIE and Mr. NORMAN DOTT on the occurrence of brain tissue within the nose, the so-called nasal glioma, with a description of two cases, one an encephalocele which in adult life became incorporated with nasal polypus, and the other case illustrated the penetration of the nasal cavity by a cerebral frontal glioma of the spongioblastic type. Mr. BRAYSHAW GILHESPY read a paper on chronic hyperplasia of the jaw and indicated certain similarities between this disease and otosclerosis. Mr. MICHEL YLASTO introduced the subject of meningitis of the frontal sinus region, which he thought might not be so infrequent as supposed. No necropsy was complete, in a case succumbing to meningitis, which did not include the opening of the sphenoidal sinus cavities in cases in which an otitic cause of the meningitis had been diagnosed. A number of cases were shown by Dr. W. S. SYME, Dr. J. A. GIBB, Dr. T. B. JOBSON, and others, and there was also an exhibition of instruments, among them a *lamp*, shown by Dr. DAN MCKENZIE, for examining a patient in bed, and, by Dr. W. H. KELSON, a clockwork burr useful in operations on the *labyrinth* and mastoid, a magnifying lens to be worn on the thumb of the operator, and an instrument for measuring the amount of protrusion of a bougie from the extremity of the Eustachian catheter.

Dr. GRAHAM HODGSON gave a demonstration of radiograms of the normal and abnormal labyrinth. He had visited recently the clinic in Utrecht where similar work is carried out. He said that owing to the number, complexity, and density of the various structures overlying the petrous bone it was difficult to get a clear view of the labyrinth, and only after elaborating a special *x*-ray apparatus and taking 1,200 views of the normal labyrinth was he able to work out the series of angles by which to obtain the desired view.

LATENT SEPSIS IN PREGNANCY TOXAEMIA.

AT a meeting of the North of England Obstetrical and Gynaecological Society at Sheffield on May 27th, Dr. CARLTON OLDFIELD in the chair, Miss F. IVENS (Liverpool) read a paper on latent sepsis as a factor in the etiology of the toxaemias of pregnancy.

Miss Ivens said that in a paper read before the London Association of Medical Women in February, 1925 (JOURNAL, 1925, vol. i, p. 589), she had drawn attention to the association of latent infection with the oedema and albuminuria of pregnancy, and had expressed the view that oedema and albuminuria during pregnancy were an indication for the bacteriological examination of the urine, even in the absence of urinary symptoms, since the causal organisms might not infrequently be demonstrated thus. The toxaemias of pregnancy—namely, oedema, albuminuria, hyperemesis, accidental haemorrhage, jaundice, and eclampsia were closely allied, and there was probably a common factor in all—namely, a bacterial origin. She had instituted a bacterial investigation in these cases as she was disappointed with the result of biochemical research. She divided the cases into four classes.

(1) *Albuminuria and Oedema.* Thirteen patients had been treated during the last two years at the Liverpool Maternity Home. In these cases the presence of coliform organisms with pus and sometimes blood was demonstrated in the urine. They were treated by rest in bed, rectal saline injections, calomel, saline purgatives, and potassium citrate in large doses. In only one case of a patient allowed to go home before delivery was the child stillborn. Of 21 cases examined bacteriologically at Crofton Hospital, 7 contained *B. coli*, 2 a non-haemolytic streptococcus, 11 a *Staphylococcus albus*, and one was sterile. Of the 7 cases with *B. coli* in urine, pus was present in 5, the conditions being respectively hyperemesis, hyperemesis with abortion and phlebitis, pyelitis, pyelitis and cystitis, and cystitis. No pus was found in one case of hyperemesis and another case of hyperemesis in which labour was followed by morbidity. Two patients had streptococci in the urine; one was a case of abortion, and the other patient, then seven months pregnant, had had ante-partum haemorrhage in previous labours, followed by pelvic abscess. (2) *Hyperemesis gravidarum.* The first case was that of a primipara who vomited constantly throughout her pregnancy. The urine contained albumin, red cells, pus cells, and coliform bacilli, and in addition there was an abscess of Skene's glands. The temperature was 101°, and the pulse 130. Rectal salines and potassium citrate in large doses were given, and 10 c.cm. of an anticoli serum. A premature infant was born which lived for sixteen hours. The vomiting continued after delivery, with raised temperature and pulse. After vaccine treatment for three months the patient was discharged with the urine practically normal and the general condition excellent. The second case was that of a 2-para who had had vomiting throughout her first pregnancy and had been prematurely delivered of a child which died on the fourth day. In the second pregnancy she was well for the first three months, but then vomited incessantly. On admission the temperature was 99.8° and the pulse 110. The patient became comatose and the vomit was haemorrhagic. The urine contained albumin, coliform organisms, and acetone and diacetic acid. A Caesarean section was performed at twenty-six weeks owing to her serious condition, and she quickly recovered. (3) *Jaundice.* The first patient was a 3-gravida admitted with vomiting, jaundice, retention of urine at eight months' gestation. The urine contained pus, bile, and *B. coli*. After treatment with purgatives, potassium citrate, and salines, improvement was marked. Labour started with excessive bleeding, but the child was born alive, though jaundiced. Rigors followed delivery, with an attack of pyelonephritis on the right side; on discharge the urine was normal. It was probable that in this case, in addition to infection of the urinary tract, infection had spread to the biliary passages. The second patient was a 6-gravida who had always vomited severely during pregnancy. Five days before her confinement she vomited blood-stained material. On admission she was jaundiced, the temperature being 97° and the pulse 120. The urine contained albumin, pus, coliform bacilli, acetone and bile; blood culture was sterile. A macerated foetus was delivered after internal version for transverse lie and prolapsed cord; 10 c.cm. of antistreptococcal serum was given, and rectal saline injections. She was quite well on discharge from hospital a fortnight later. (4) *Accidental Haemorrhage.* The first patient was a 3-gravida on whom a Caesarean section had been performed in 1924 for contracted pelvis. In 1926 she was delivered by Caesarean section for severe ante-partum haemorrhage; there was blood-stained fluid in the peritoneal cavity, and haemorrhages into the wall of the uterus. The child was dead. The urine contained a trace of albumin, coliform organisms, and streptococci; coliform organisms were recovered from the *placenta*. In 1927 a third Caesarean section was performed; the urine was normal, and the patient appeared perfectly healthy. The second patient was a 5-gravida whose first three pregnancies and deliveries were normal. In her fourth labour there was *concealed* accidental haemorrhage. She was delivered, by Caesarean section, of a dead child. There was haemorrhage into the wall of the uterus, and the urine contained pus and coliform bacilli. In her last pregnancy in 1925 labour was premature. She had oedema and

vomiting for five weeks previously, and the urine contained albumin, coliform organisms, and streptococci. The placenta showed areas of white infarction and round-celled infiltration. The third patient was a 6-gravida delivered by Caesarean section, for placenta praevia, of a child weighing 4 lb. 5 oz. Haemolytic streptococci and staphylococci were found in the wound, and the urine contained a trace of albumin with staphylococci. The child died on the fifth day after haemorrhage from the mouth and nose. The fourth patient, an 8-gravida, was admitted almost moribund with ante-partum haemorrhage; she died soon after delivery of a macerated foetus. Cultures from the placenta contained coliform bacilli and streptococci, but no urine was obtainable for examination. The fifth patient was a 7-gravida with concealed accidental haemorrhage, and Caesarean section was performed. Blood-stained fluid was in the peritoneal cavity, and the uterus showed intramural haemorrhages. The child was dead, and the patient died immediately after operation. The urine contained albumin, staphylococci, and streptococci. The placenta gave growths of *Staphylococcus albus* and a non-haemolytic streptococcus. A varicose ulcer on the patient's leg contained *Staphylococcus albus*. The maternal liver showed hyaline thrombi. The kidneys contained hyaline thrombi with areas of coagulation necrosis; the uterine muscle stained badly and showed haemorrhages.

In conclusion, Miss Ivens said that she had hoped to stimulate interest in the bacteriological investigation of similar cases, for she was convinced that latent and autogenous infection played a great part in the pathology, especially of cases with lowered resistance during pregnancy, and of those delivered with trauma. She considered it necessary to obtain a full life-history of these patients, and evidence of foci of infection should be looked for in the throat, gums, and elsewhere. Professor Beattie, Dr. Ashcroft, and others had assisted in the bacteriological investigation.

Dr. CARLTON OLDFIELD (Leeds) agreed that urinary infections were very commonly associated with albuminuria. There was danger sometimes of assuming when organisms were present that they were the cause, when in reality they were the result, of some pathological condition. He still was of the opinion that hyperemesis gravidarum was not due to a toxaemia.

Mr. A. GOUGH (Leeds) said that it was not sufficiently realized by practitioners how often the genito-urinary tract was infected. Of 100 gynaecological cases examined bacteriologically by him, in 70 cultures of bacteria were obtained, of which 10 were growths of *B. coli*. He explained the preponderance of *B. coli* infection on the ground that this was a mobile organism capable of swimming up stream, and of rapid proliferation.

Mr. J. E. STACEY (Sheffield) said that at the Jessop Hospital, Sheffield, they had been struck with the number of cases of morbidity during the puerperium in those patients with albuminuria during pregnancy and labour.

Dr. S. B. HERD (Liverpool) asked if there was any definite association in Miss Ivens's cases between sepsis during pregnancy and morbidity during labour and the puerperium.

Miss IVENS replied that she had instituted a bacteriological investigation in her cases of toxaemias of pregnancy because the biochemical investigations had not yielded any clues as to their causation, and she had been impressed by the findings. She had noticed that cases of latent sepsis did not do so well in the puerperium as normal cases.

Calculi in a Case of Procidentia.

Mr. J. E. STACEY (Sheffield) showed calculi removed from a case of complete procidentia. The patient was a 4-gravida, aged 41, who had had falling of the womb for four years. The uterus had been outside the vulva for a year, although a ring pessary was worn. The only urinary trouble was occasional scalding micturition and frequency. The urine was alkaline, and contained pus and coliform bacilli. On examination the largest stone could be felt in the cystocele and the rest in the main body of the bladder. The ten stones shown had been removed by an anterior vaginal wall incision and cystotomy. After treating the cystitis and ensuring closure of the vesical wound, the uterus was removed three weeks later by the vaginal route with anterior and posterior colporrhaphy. The stones weighed 9¾ oz.; they were laminated and consisted chemically of sodium carbonate, ammonium urate, and a triple ammonium magnesium phosphate. They were examined by *x* rays to eliminate the presence of a foreign body as a nucleus.

Dr. CARLTON OLDFIELD (Leeds) said that in his experience stones in the bladder were exceedingly rare, and asked if the urine was ammoniacal.

Mr. A. GOUGH (Leeds) referred to a case of vesical calculus which he had reported to the society some years previously. This was a single stone weighing 12½ oz., which he had removed by suprapubic cystotomy, the wound of which was very slow in closing.

Miss IVENS (Liverpool) recalled a severe case of procidentia with vesical calculi, which had caused a vesico-vaginal fistula, through which they had been discharged from the bladder.

Dr. J. W. BRIDE (Manchester) had removed a small stone from the bladder by lithotrity, and had assisted Professor Fletcher Shaw to remove one by vaginal cystotomy.

Dr. J. PHILLIPS (Bradford) had seen two cases with small calculi enclosed in a diverticulum from the urethra from which they had been excised.

Mr. STACEY replied that the urine was ammoniacal when he first saw the patient. He considered the vaginal route much the best, as healing of suprapubic incisions was very slow.

Pregnancy Complicated by Fibromyoma.

Dr. S. B. HERD (Liverpool) read notes of a case of pregnancy complicated by a necrobiotic fibromyoma and later by accidental haemorrhage. The patient, a primigravida, was first examined at a period of twelve weeks' gestation, and a soft non-tender swelling was detected high up on the right side of the uterus; this was diagnosed as a subserous fibroid. At seventeen weeks' gestation the patient had acute dysuria and feeling of great pressure in the vagina and region of the symphysis pubis. On examination the uterus was felt to be displaced by a hard tender mass fixed in the right side of the pelvis; diagnosis of degeneration of the fibroid was made. As it was impossible to move the tumour under anaesthesia the abdomen was opened and a degenerated fibroid was removed from the uterine wall just above the right utero-sacral ligament, with some difficulty and not without a great deal of manipulation of the body of the uterus. No other fibroids were present. The patient was kept under the influence of morphine for a few days to diminish the chances of abortion, which treatment succeeded. On the fifth day there was thrombosis in the right leg which was believed to be due to lack of exercises ordered. The patient remained quite well until thirty-two weeks' gestation. A violent headache then developed; on the next day foetal movements ceased to be felt and she had slight oedema. Two days later there was marked oedema, and 16 grams of albumin per litre in the urine; the foetal heart sounds were heard on that day. Two days afterwards there was sudden onset of pain and vaginal haemorrhage, and morphine was administered. Three days later a slightly macerated foetus was delivered. The puerperium was normal. The special points in this case were the persistence of the pregnancy after marked manipulation of the uterus; the supervention of toxaemia followed by accidental haemorrhage; and the fact that the foetal heart was heard for three days after the perception of movements had been lost.

Dr. CARLTON OLDFIELD (Leeds) did not think that the lack of exercises should be blamed for the thrombosis. He suggested that the necrobiosis in the fibroid had set up toxaemia in the first place, causing a retro-placental clot which gave rise to placental changes and later to albuminuria and accidental haemorrhage.

Dr. E. O. CROFT (Leeds) said that it was surprising how much manipulation a pregnant uterus would stand without aborting, and recalled a similar case of myomectomy.

Mr. STACEY asked what would have happened if operation had not been performed. He had seen a pregnant patient with a large fibroid in the fundus and symptoms at seven months' gestation. It was treated expectantly and settled down. The patient had a placenta praevia, and the child was stillborn. On the ninth day of the puerperium symptoms again arose, and myomectomy was successfully performed.

Miss IVENS (Liverpool) recalled a case in which three weeks before term induction was attempted by bougie for a contracted pelvis. Introduction of a bougie caused severe bleeding and it was withdrawn. At term Caesarean section was performed and a large retro-placental clot was found. There had been no albuminuria in the meantime.

Mr. W. GOUGH (Leeds) related a case in which a fibroid the size of a hazel nut gave rise to such severe pain during pregnancy that operative treatment had to be undertaken. Myomectomy cured the condition.

Dr. HEAD replied that there was an interval of fourteen weeks between the operation of myomectomy and the onset of the albuminuria in his case, and he submitted that this was too long for the latter to be due either to the necrobiosis or to retro-placental clot caused by the uterine manipulation. He said that in this case the position of the degenerated fibroid would have obstructed labour even at the early period of eighteen weeks' gestation, and so an operation was essential.

Pelvic Myxoma.

Mr. A. GOUGH (Leeds) described a case of pelvic myxoma in a multipara aged 35. She had noticed a swelling in the left gluteal region at least twelve years previously, and others had later formed in the abdomen, perineum, and vulva. Four operations had been performed between 1915 and 1924, during one of which the large gut had been damaged, necessitating a colostomy which only closed several months later. Menstruation was normal, and the functions of the bladder and rectum were unimpaired. There was a mass filling the left lower quadrant of the abdomen, the overlying skin of which showed the scars of previous operations. The tumour could be traced over the pubis to the left labium majus, where it formed a huge pedunculated mass hanging down nearly as far as the knees. The circumference of the upper part was 15½ inches, of the lower end 22 inches, and the total length from the pubis was 11 inches. The skin over it was thinned and purplish in colour. The tumour could be traced backwards into the left buttock, where there was a mass the size of an adult head. The tumour was painless and felt spongy and elastic with some coarse lobulation. Vaginal examination was unsatisfactory, but the left side of the pelvis was found to be full of growth continuous with the superficial masses and displacing the vagina and rectum to the right. Complete removal was impossible. At the first operation the pendulous portion was removed at its origin at the level of the pubis, and weighed 5 lb. 1½ oz. Four months later the gluteal mass was removed. Cystic spaces were noted in both masses. Microscopical examination showed the typical structure of a myxoma. The cystic spaces were bounded by layers of condensed stroma, no epithelial lining being demonstrable.

Dr. CARLTON OLDFIELD said that it was very difficult to deal with these cases. He had operated on one patient several times. He suggested deep *x*-ray therapy.

Mr. GOUGH, replying, said that he had discussed *x*-ray therapy with a radiologist, who expressed the opinion that it was useless in these cases.

Solid Ovarian Tumour with Twisted Pedicle.

Mr. GOUGH also described a case of a large solid ovarian tumour with a twisted pedicle. The patient, aged 52, was seen two years after the menopause; she had known of the presence of an abdominal tumour for seven years. This had recently increased rapidly in size, and she had then had pain, vomiting, diarrhoea, and frequency of micturition; her health had rapidly deteriorated. She was very pale and thin, and the abdomen showed the presence of a tumour larger than a full-term pregnancy; it was tender on palpation and dull on percussion. On vaginal examination the cervix appeared to be continuous with the tumour. The pulse was 120 and weak; the temperature was normal. The urine contained pus, albumin, and coliform bacilli. The haemoglobin percentage was 40; the red corpuscles numbered 1,965,000 per c.cm., and the white corpuscles 27,000. The diagnosis was uterine myoma, probably degenerating, and possibly suppurating. Four days before the operation the patient was given a transfusion of 20 ounces of blood, which greatly improved her condition. At the operation the tumour was found to arise from the left ovary; it had twisted its pedicle to the size of a finger, and was lightly adherent to abdominal contents. It was easily separated and removed. During convalescence there was an exacerbation of the infection of the urinary tract. The tumour weighed 13¼ lb.; its surface was smooth and showed red and yellow mottling. On section it resembled the spleen. The specific structure only showed near the surface, and was seen to consist of long fusiform cells with rod-shaped nuclei. Leucocytes were also present. The cause of the profound anaemia was probably loss of blood in the tumour, possibly also the absorption of haemolytic toxins.

Dr. OLDFIELD believed that in cases of fibroids of the uterus there was some other cause for the anaemia than simple loss of blood. He had operated on many anaemic cases of fibroid, but had never thought it necessary to transfuse them before operation.

Dr. CROFT thought that long continued bleedings produced a more permanent and dangerous anaemia than single large haemorrhages.

Mr. GOUGH replied that he considered that in some of these very pale women transfusion with blood was a very useful method of pre-operative treatment.

TREATMENT OF MENTAL EXHAUSTION AND DRUG ADDICTION.

AT a meeting of the Brighton and Sussex Medico-Chirurgical Society on June 2nd, with the President, Dr. E. RIVAZ HUNT, in the chair, Dr. E. R. FOTHERGILL opened a discussion on the treatment of mental exhaustion and drug addiction.

Dr. Fothergill commenced with the warning that the mental and spiritual attributes of patients must not be ignored, since health was the harmonious co-operation of these with the physical attributes. The proposal that ministers of religion should attempt to cure physical and mental troubles solely by dealing with the spiritual aspect was to be deprecated. The two professions should co-operate, but the medical practitioner must be in control. Dr. Fothergill then explained that in discussing mental exhaustion he would not touch on this in relation to disease or injury, nor on its effects in childhood and youth. Mental exhaustion in the adult, apart from disease or injury, manifested itself in excessive emotional reaction, anxieties and loss of confidence, with irritability, failure of concentration, disproportionate fatigue, indigestion, emaciation, dread of insanity, delusions and phobias, sleeplessness, and innumerable other nervous symptoms. The advice of friends to the sufferer from mental exhaustion was generally worse than useless, and until the patient settled down to deal with his trouble, and stopped thrusting it back into the subconscious, all efforts at treatment would fail. The right atmosphere, and the services of an attendant, should be obtained. The patient should go to bed, and after the usual constipation had been dealt with he should be given full diet. He should then be encouraged to allow his brain to rest until the physical state had been re-established, by which time many of the symptoms would have disappeared. It would then be time to discover from the patient the cause of his illness, and to treat it. The patient would be better able to respond to encouragement, and to give the doctor his confidence. As much sleep as possible should be ensured, and Dr. Fothergill in this connexion alluded to the use of barbituric hypnotics. At first no books or papers should be allowed, but after a while the patient would probably ask to see a picture paper; this date should be noted. The relatives should not have any communication with the patient, with the exception of an occasional postcard, but they might give assistance in disclosing the cause of the illness. Records of weight should be taken at intervals of fourteen days. The patient must first be induced to believe that there was no physical or mental disease, and that his trouble could be dealt with; he must cease deploring the past, and dreading repetition of it, and be encouraged to turn his thoughts to the future constructively. The whole outlook had to be readjusted, and this was best brought about by the

patient himself under the tactful and sympathetic guidance of a doctor who could place the facts in their right position and their right proportion. It must be explained that his case was analogous to that of friends on the telephone, unable to converse because they had not been connected; it was not a case of the batteries requiring recharging. The patient must be got to realize that it was in himself that he would find the clue to the breakdown and to the re-establishment of normal functioning. Relatives might regard the question of certification with horror, or find it attractive for ulterior reasons. Great care must be exercised. There were many people of undoubtedly unsound mind who could be brought back within a very short while if suitably treated. Should certification be delayed on this account, it was advisable for the delay to be approved by a second medical practitioner, and for the facts to be placed before the Board of Control. With regard to our knowledge of mental exhaustion in industry, this was the pooled result of experiences in the case of individuals. The medical profession should protest against destructive influence on the body and soul due to the extensive mechanization of industry. To combat this influence more effectually the medical practitioner should communicate the experience gained in dealing with cases of mental exhaustion in private practice to those engaged upon the work in larger fields. Passing to the question of drug addiction, Dr. Fothergill said that, excluding alcoholism, this condition was, in his experience, found only among intellectuals. Without corroborative evidence no statement by an addict was reliable. A voluntary addict, without the excuse of disease or injury, must be regarded as having been potentially mentally unbalanced. If this was accepted, then treatment followed similar lines to that of mental exhaustion, since it would be useless to treat the drug addiction without dealing with the underlying cause. Drug addiction as the result of disease or injury became increasingly difficult to treat when the physical reasons for giving the drug were gone. In the absence of disease or injury the treatment was by gradual reduction; in the case of alcohol, at the commencement; with morphine and its derivatives, at the end. The medical practitioner must be certain that no drugs could reach the patient without his knowledge or that of the attendant. The amount of liquid in the barrel of the syringe, or the size of the suppository, must never be varied. As the treatment progressed, and the strength of the dose was decreased, it must be remembered that the patient would become more difficult to handle.

HEART-BLOCK.

AT a meeting of the Section of Medicine of the Royal Academy of Medicine in Ireland on May 20th, the President, Dr. G. E. NESBITT, showed a case of complete heart-block.

The President said that the patient was a man, aged 62, who had been admitted to hospital a week previously, complaining of swelling of the abdomen and shortness of breath. His symptoms had begun about nine months previously, before which time he had been perfectly healthy, and for most of the nine months he had been taking digitalis in large doses. His heart was extremely slow (36-40), but quite regular. The abdomen contained fluid, 64 ounces having been removed the previous day, when the liver was found to be enlarged. The electro-cardiograph showed slow ventricular complexes of normal shape, though much exaggerated in Lead 3; peristaltic waves were entirely absent, and there was also evidence of right ventricular preponderance. An *x*-ray examination disclosed an enormous heart shadow. The Wassermann reaction was negative. After the subcutaneous injection of 1/50 grain of atropine the pulse rate rose to 52 in about half an hour, but soon resumed its former level. The President added that the case appeared to be one of complete heart-block with auricular fibrillation. In view of the history of prolonged administration of digitalis the question of the possible causal connexion of this drug would arise. Except experimentally, digitalis did not appear to cause complete heart-block of this type, and no other evidence of toxic effects had been present. There was also a suspicion that the liver might be the seat of malignant disease. Electrocardiograms from another recent case of typical complete heart-block were also shown.

Dr. H. T. BEWLEY said he had encountered a few cases of complete heart-block, but none of them were associated with digitalis. He asked if Dr. Nesbitt's patient had suffered from fainting attacks, as he had had a patient with such a condition in whom the pulse was 28, and there were periods, of from four seconds, in which it was impossible to detect the heart beat. This patient gradually recovered, and lived for several years a quiet life, but it had taken some time for the heart to become accustomed to the very slow rhythm, and during this period the patient had had very severe attacks of fainting, and had several times nearly died.

The PRESIDENT, replying, said that he had proved that the condition in this patient was not due to digitalis, but he thought that time would decide how much, if any, of the condition might be attributed to digitalis. The patient's pulse had never been below 36, and he had never suffered from fainting attacks.

Mikulicz's Disease.

Dr. J. SPEARS showed a case of Mikulicz's disease in a woman, aged 50. She had been having *x*-ray treatment. Nothing abnormal was found in the blood, but septic teeth had been removed. She was deaf, but it was not known whether the deafness was due to Mikulicz's disease or not; the drums were normal, and the deafness was of the middle-ear type. She had never complained of pain, but after the *x*-ray treatment she had had a slight rise of temperature on three occasions.

Dr. A. R. PARSONS believed that the present case was the fifth of *Mikulicz's disease reported in* Dublin during the last twenty-five to thirty years. The condition was probably not a definite entity, but occurred in various classes of conditions; most cases proved to be leukaemia or Hodgkin's disease. He regarded *Mikulicz's disease as* merely a syndrome, which might change into one of these other diseases, in which enlargement of the glands and of the spleen was always found.

Mycosis Fungoides.

Dr. J. M. O'DONOVAN read notes on a case of mycosis fungoides, and showed photographs. The patient, a young woman, presented six red tumours; four on the scalp, one over the sternal end of the right clavicle, and one over the sternum. Examination of the blood and urine was of no diagnostic assistance, and the Wassermann test was negative. Exhibition of potassium iodide produced no improvement in symptoms or in the tumours, of which those in the scalp had ulcerated. The condition cleared up completely under *x*-ray treatment, and the patient had been well for five months. A remarkable feature of the case was the relatively acute onset, and the entire absence of prodromal pruritus.

The PRESIDENT said that the condition was one which he thought was not well known except theoretically. Dr. O'Donovan's result obtained so far was remarkable, since it was generally thought that these cases were progressive, and that the issue was uniformly fatal.

Dr. E. T. FREEMAN said he had seen two cases of mycosis fungoides in France in 1922, and he agreed with the diagnosis made by Dr. O'Donovan. One of his own cases resembled that of Dr. O'Donovan; there had been no pre-mycotic stage at all, and the tumours had appeared initially. It was a feature of the disease that the tumours might completely disappear after treatment by *x* rays and reappear many years later.

Dr. W. G. Harvey said he had never seen previously a case which had started with tumours only; he had encountered a few cases which had started with a pre-mycotic stage, but in all his patients the tumours had disappeared after *x*-ray treatment, but after a time had returned. He thought that a time came when these tumours ceased to respond to *x* rays. The absence of recurrence in the present patient was somewhat against the diagnosis of mycosis fungoides.

Cure in Diabetes Mellitus.

Dr. J. M. O'DONOVAN read notes on a case of diabetes mellitus in a man aged 60, presenting glycosuria, acetone bodies in the urine, and hyperglycæmia. On an Allen diet he required at first sixty, then forty units of insulin to produce tolerance. In two months after discharge from hospital he was able to increase the diet, and after progressive diminution of the insulin, to stop it and revert to a diet normal in all respects save the inclusion of sugar.

The PRESIDENT, referring to the possibility of a cure in diabetes, stated that great improvement occurred in a very large number of cases of diabetes. He could remember many patients who after treatment by insulin had returned to work, and remained well, while taking insulin after discharge from hospital; he thought that in many of these the function of the pancreas must have improved. He generally gave insulin to his patients in two doses daily, one after breakfast and one after dinner; he did not give early in the morning.

Dr. J. SPEARS referred to the case of a man about 50 years of age with diabetes. He had at first sugar, diacetic acid, and acetone in his urine, but subsequently the urine became normal and had remained so for six months. He, however, came back to hospital with gangrene in his toe, and amputation was required.

Dr. W. H. ASHMORE said he had recently seen a man who had been in Egypt in the hot weather, had returned to London, and had been found to be suffering from diabetes. He was dieted, and had no sugar in his urine, but acetone. Dr. Ashmore decreased the carbohydrates, following which the acetone disappeared, and the patient returned to full diet without recurrence of acetone or sugar. This suggested that the condition known as acute diabetes did occur. He had also had a patient with bad pyorrhœa, who had acetone and sugar; after dieting and removal of his teeth he had remained free from both sugar and acetone. He thought that in diabetic cases an ordinary diet with low carbohydrates and a high quantity of fats was not good. In these cases if the acetone and diacetic acid were removed the sugar often disappeared.

Dr. V. M. SYNGE referred to the case of a man, aged 22, with severe diabetes, who stated that five years previously had had exactly the same symptoms—wasting, polyuria, and thirst. At that time he had been in hospital and had been dieted, and had become sugar-free. When he went back to the country, however, he had ceased to diet, and had remained well for five years. Then, a couple of months prior to admission to hospital for the second time, the symptoms had recurred. This was a case in which the diabetes had at first been of a temporary nature.

Dr. A. R. PARSONS thought that cases of diabetes were not cured by insulin, but that it was of tremendous value in dealing with some emergencies; it undoubtedly greatly mitigated the dangers of acidosis.

Dr. O'DONOVAN, replying, said that while his patient had been in hospital he had tried several times to reduce the dose of insulin; each time he had done so the sugar returned, and so he thought it was obvious that units was the dose necessary to keep him aglycosuric. hen the 40 units was given in one dose the patient ained without sugar for twenty-four hours, but if the e amount of insulin was given in two doses the patient not remain without sugar for as long as twenty-four rs.

Death due to Mediterranean Fever.

J. SPEARS read notes on a fatal case of Malta fever. patient had had several febrile attacks at intervals he had come to Ireland; it was thought that they of malarial origin. He was obviously anæmic, per- greatly, and except for a very definitely enlarged presented no clinical findings. His temperature 0°; the pulse was 104, the respirations 20, and the was coated. The abdomen was quite soft, and his mplaint was of intense headache, thirst, and night tions; his appearance was strongly suggestive of fever. Several blood films were examined, but no of any malarial or other protozoal infection was He was very constipated through his illness. A and a Widal test were negative to typhoid and paratyphoid strains. The only complication was a slight orchitis, which sometimes occurred in cases of undulant fever. The agglutination against *M. melitensis* gave a positive result of 1/125. The remaining course of the illness included progressive weakness, prostration, sweats, and slight rheumatic pains. Various remedies were tried without any success.

Professor J. W. BIGGER stated that the diagnosis could not be proved in this case, as it had not been possible to isolate the organism. If the patient had at any time suffered from Malta fever his blood would still agglutinate, and, therefore, there was no certainty that the case was one of Malta fever. Referring to the duration of the disease, he said that this infection was notoriously protracted, with periods of remission. There was a theoretical possibility of infection with *B. abortus*, the presence of which in human beings had recently been reported.

Belladonna Poisoning.

Dr. J. SPEARS read a note on a case of suspected belladonna poisoning. A man, aged 32, gave a history of having had dysentery in India in 1917, and was treated with emetine injections as a suspected case of *Entamœba histolytica* infection; from this he recovered. Later on he suffered from constipation, which had become worse. According to his own account he sometimes took an ounce or more of the extract of cascara sagrada every day, and had tried various other aperients with no good result. He also had had attacks of sore throat and felt very weak. He had lost 7 lb. in weight during the last three months. He had no cough, no night sweats, and no urinary trouble. His speech was drawling and deliberate, and though his thoughts were quite clear, yet his cerebration appeared to be very slow. He complained of great weakness and had to move about very slowly; he felt very drowsy in the day-time. He was considerably emaciated, and dragged his legs when walking; his pulse rate was 48, his blood pressure 100 to 110 systolic and 60 diastolic. The heart sounds were feeble, but there was no bruit. His teeth were sound, his tongue coated but dry, the skin very dry, the lungs clear, breath sounds showed no abnormality, the eye reflexes were normal, the knee-jerks were very sluggish, there was no Babinski reaction, no ankle clonus, and his superficial reflexes were present and normal. Sensation tests were normal, but the response to questions was slow. The urine was normal. The movements of his diaphragm were somewhat limited, and the Wassermann test was negative. His temperature continued subnormal. Aperients and various enemata were tried with no good result. The prescription given to him for his constipation in 1917, after he had recovered from dysentery, contained belladonna, and it appeared that he had been taking from 1 to 2 drachms of the tincture of belladonna every day for the preceding six years. The stools showed no fat abnormality, although the patient said that fat had a sickly effect on him, and there was no definite evidence of a pancreatic lesion. He gradually became weaker and death ensued. The interest in this case lay in the probable diagnosis of chronic belladonna poisoning. The pupils did not become markedly dilated until the close, the pulse rate never rose over 54, and his temperature only reached 99 just before death.

Dr. W. H. ASHMORE commented on the absence of tachycardia, mania, increase of respirations, and dilatation of the pupils. It was quite possible that this patient had a very high toleration for belladonna.

Dr. SPEARS, replying, said that while no other cause for the condition could be found, there was definite evidence that the patient had been taking large and gradually increasing doses of belladonna for a number of years. This made him suspect chronic belladonna poisoning. The features were not definite, and there was no case on record for comparison. He thought he was justified in thinking that the cause of death was perhaps due to stopping the belladonna, but that the initial cause of the patient's trouble was the taking of large doses of belladonna. The patient could read only with difficulty, but Dr. Spears could not make out whether this was due to his slow speech or to bad vision.

Reviews.

A VADE-MECUM OF PARASITOLOGY.

THE small work written by Professor LOISELET is rightly designated a *Vade-mecum*,[1] and adequately fulfils the object for which it has been issued—namely, to provide a volume easily carried for the purpose of facilitating diagnosis. It presents a sketch of the various species of interest and importance to the student of parasitology, and only a master of his subject could thus condense the enormous amount of information found here.

The whole is divided into five parts, dealing in order with the spirochaetes, protozoa, helminths, arthropoda, and the mycoses. The consideration of each member referred to in the ensuing pages of its proper section is preceded by a synoptic table naming in different columns the diseases produced, the vector concerned, the mode of transmission, and, where such exists and is known, the reservoir host. Other tables give in few words the chief points relative to the life-histories of the most important members of the various groups and the characters to be relied upon for identification. To the last section is appended a "mycological glossary" in which are stated the salient characters, the aspects of cultures, and the pathogenic actions of the chief mycotic infections.

Misprints are few and the arrangement of type is such that reference is made particularly easy. We note that a considerable proportion of the specific names are spelt with capital initial letters, to which systematists will properly object. The book does not aim at replacing the detailed textbooks, but as a work to refer to by those who have already been through courses in the subjects dealt with it will serve a useful end, in that it is at once simple and practical.

THE "FAT-LIKE" SUBSTANCES.

THE nine years which have elapsed since the appearance of the first edition of *Lecithin and Allied Substances*,[2] by Professor HUGH MACLEAN, have witnessed no revolution in the chemistry or the physiology of these substances. Such advance as has been achieved has been towards simplification and co-ordination. A revision of this monograph is, none the less, welcome. The duty which is undertaken by authors of monographs in such a series as that to which this volume belongs is not light, since this service to their colleagues requires that they should constantly return to the labour of bringing their text up to date. In the second edition Mrs. IDA SMEDLEY MACLEAN shares authorship with her husband.

The original form of the narrative is little altered. The opening sections on the history and chemistry of the accepted members of the group of lipins now includes the recent work of Levene on lecithin and kephalin. There follows an adequate detailed account of the preparation of these substances—if any detail is adequate to overcome the vagaries in the chemical behaviour of the lipins. The "fat-like" substances of tissues form distressing material for the chemist. Theirs is a fickle waywardness and inconsistency of behaviour which is too human to fail to be exasperating. It has been responsible for the identification as distinct bodies of what now appear to be mixtures of closely related substances. The history of the lipins has been in great part taken up with the separation of the sheep from the goats. A chapter is devoted to the more notable of these discredited individual bodies, and may raise the objection that it unnecessarily crowds the detail of the picture. It will, however, be agreed that the record of error is not without value to the worker in this field.

The brief discussion of the chemistry of the plant lipins serves merely to indicate our almost complete ignorance. Little more satisfactory is the state of knowledge of the physiological function of the lipins in the animal or plant economy. They are present in every living cell, and their place in its integrity and function seems to be fundamental. Beyond this there is little that is not conjecture. The truth is, that their unusual solubilities endow them with a peculiar relation to the structure of the cell which we are far from being in a position to comprehend. The authors are content to review briefly the alleged role of the lipins in the transport and metabolism of the fats, in the physico-chemical structure of the cell, in the cell membrane, and in the clotting of blood.

The question of nomenclature has disturbed the authors as it disturbs all biochemists. They are, probably, wise in adopting tentatively the system employed by Professor Leathes in his companion monograph *The Fats*. Some day national and international bodies may be expected to take the trouble to get together and agree upon an acceptable descriptive nomenclature.

As is the case with all the volumes in this series, the bibliography is extensive and valuable.

A TEXTBOOK OF BIOCHEMISTRY.

WE are threatened with a surfeit of textbooks of biochemistry. The example before us,[3] from the pen of Professor J. B. SUMNER, reminds us that the larger crop springs from the fertile soil of the progressive impatience of American schools of medicine. The reason is not far to seek. Departments of biochemistry have been creeping from under the wing of physiology to lead an independent existence. Manuals for their guidance have been limited, and each has sought to work out its own salvation in a systematized curriculum. The temptation to offer the fruits of such labour to a larger audience is strong, and will not be overcome until a process of natural selection singles out the fittest teacher. The present volume is not inspired, but does seem to offer a more judicious course than have several recent books with a similar aim.

The usual treatment is followed of dealing in succeeding chapters with the chemistry and physiology of the fats, carbohydrates, proteins, urine, and blood. Brief chapters are also devoted to acidosis, vitamins, calorimetry, and detoxication, and longer ones to enzymes and to the physico-chemistry of protoplasm. A certain arbitrariness in the broad statement of some biochemical principles will be occasionally encountered and will distress the teacher, though this may do little harm to the student. Such a statement is that which lays down that "the essential difference between the plant and the animal is that the reactions of the former are to a large degree anabolic, while the reactions of the latter are for the most part catabolic." This is an expression of the prejudiced interest of the biochemist rather than of any intrinsic difference in animal and vegetable physiology.

The book is addressed to "the elementary student"—presumably inclusive of the student of medicine. To such it may be recommended.

FAMILIAL PLEONOSTEOSIS.

THE book on diseases of the bones and joints[4] by ANDRÉ LÉRI is not, as the title might suggest, a systematic treatise, but a collection of papers which have appeared from time to time in the journals. The first article refers to a disease which the author claims that he was the first to recognize and describe—namely, familial pleonosteosis; other articles embody original observations touching details in the pathogeny and clinical characters of such diseases as cleido-cranial dysostosis, Paget's disease, anencephaly, and many others. A comparatively small part of the

volume is devoted to diseases of the joints, since most of the author's publications on this subject relate to the vertebral column and formed the subject-matter of a previous volume.

The article of chief interest in the book is, perhaps, that on familial pleonosteosis, which appeared in the *Presse Médicale* for January 7th, 1922. The disease affects the whole skeleton, but more especially the long bones; it is congenital, hereditary, and familial. Its main characteristics are deformation of the hands, with immobilization of most of their segments, certain fixed attitudes, such as pronation and flexion of the forearms, internal rotation and abduction of the arms, and external rotation of the thighs, with a reduction in the range of almost all movements. The hands are short, thick, and square; the proximal interphalangeal joints are flexed at a right angle and firmly ankylosed, with the heads of the proximal phalanges projecting beyond the bases of the second. The metacarpal bones and phalanges are short and, as revealed by radioscopy, markedly thickened, and a similar thickening is present in the other long bones of the limbs, and appears to be the main anatomical characteristic of the disease. The thickening is especially marked at the articular ends of the bones, and is apparently the cause of the limitation of movement.

MURDER AND FORGERY.

DURING the years since the armistice there has been, if we may judge by the publishers' lists, a growth of popular interest in notorious murders. The volumes of the "Notable British Trials Series," several of which have been noticed in our columns, possess for the most part a medico-legal interest, since they contain reports of the proceedings which are not easily accessible elsewhere. A book recently published, *Murder for Profit*,[5] by Mr. W. BOLITHO, is in a very different category. It contains picturesque narratives of five notorious murders, two British and three Continental, and some inkling of the writer's point of view may be got from the titles he has bestowed upon the five essays. They are: "The science of William Burke"; "The imperialism of J.-B. Troppmann"; "The philanthropy of Desiré Landru"; "The self-help of G. J. Smith"; and "The poetry of Fritz Haarmann." Except perhaps in the case of Smith, these titles seem to us remarkably inappropriate. As far as we can guess from his outpourings, Mr. Bolitho must be a rebel who resents laws, and would ridicule the attempts of society to enforce its whose final detection and execution signalized their failure. He seems to have a particular spite against Napoleon III and M. Clemenceau, and he implicates them more particularly in the blame which he bestows so generally.

The stories of Burke and of Smith are probably well known to most readers, while Landru's case occupied so much of the foreign news in the journals of a few years ago that there is little need to retell the story. That of the Alsatian Troppmann does little credit to the police of the Second Empire, while Haarmann's career of murder, involving at least twenty-four victims—he himself said "thirty or forty"—reveals the shocking state to which social life in Hanover was reduced by four years of war, when the ever-present and all-powerful hand of the State relaxed its grasp.

A century ago a work in several volumes appeared, entitled *Celebrated Trials to the Year 1825*, in which were detailed the chief facts in a number of cases which mostly ended at the gallows. There was in it no pretension to instruction, and there can be little question but that the compilers were animated chiefly by a desire to curdle the blood and make creep the flesh of their readers. To sup full of horrors is still a fearful joy. The volumes of the "Notable British Trials Series" vary a good deal in interest. Kate Webster's murder of her employer at Richmond, Surrey, in 1879 was a sordid crime committed for gain by a brutish habitual criminal. The fact that the body was dismembered and its fragments disposed of in various places does not lend interest, for *post-mortem* dismemberment seems to have become common.

Another volume of the series deals, not with murder, but with forgery.[6] Henry Fauntleroy, the forger, was a partner in a Berners Street bank, and by an ingenious system of false book-keeping converted to his own extravagance £400,000 of the depositors' Government securities. Outwardly he was most irreproachable, living in a non-conformist atmosphere. His father had been managing partner and the brains of the bank, and the son, who lived in constant suspense that he would be caught in his complicated system of fraud, sought an anodyne in expensive distractions. After ten years of this life the blow fell; he was arrested and, after a trial which lasted two days, was condemned, and on November 30th, 1824, was executed outside Newgate Prison. Among the other forgers whose misdeeds are related in this volume are John Ayliffe, John Rice, the brothers Perreau, one of whom was a fashionable apothecary, the Rev. Dr. William Dodd, on whose behalf Dr. Samuel Johnson worked so strenuously, Henry Weston, Henry Cook, and John Hadfield. Rowland Stephenson, M.P., escaped to America with £70,000, spending the last night before his flight in St. Bartholomew's Hospital, of which he was the treasurer. The last forger to suffer the death penalty was Thomas Maynard in 1829; in 1837, after some years of discussion, capital punishment for forgery was abolished.

Why poisoners should choose arsenic, which preserves the body of the victim and can be detected many years afterwards by straightforward methods of chemical analysis, is one of the puzzles of criminology. The only explanation seems to be that the symptoms of arsenical poisoning are well known to simulate those of gastro-intestinal disease due to natural causes, and that arsenic is, or was, easily procurable for such purposes as killing weeds. The Armstrong case, of which a full report, with commentary, is given by Mr. FILSON YOUNG in the *Trial of Herbert Rowse Armstrong*,[7] must be fresh in the memory of most readers of the daily newspapers. It aroused great excitement at the time among the general public, and it had features of considerable interest for the medical and legal professions. The medical interest of the trial turned largely on the *post-mortem* findings, and on the symptoms of arsenical poisoning shown by Armstrong's wife on two occasions—in August, 1920, before her removal to an asylum, and in the following February, soon after her return home. It was common ground between the prosecution and the defence that she died on February 22nd, 1921, of poisoning by arsenic. The amount actually found in her body (3¼ grains) was the largest ever found by the late Mr. John Webster, the Home Office analyst, during many years' experience of such examinations. The legal interest turned largely on the admissibility, as evidence on the capital charge against Armstrong, of evidence pointing to the attempted murder by him (again with arsenic), eight months after his wife's death, of a fellow solicitor named Martin, between whom and himself some business difficulty had arisen. Armstrong's motives for murdering his wife seem to have been the desire to benefit under a new will, drawn up by him for her and irregularly attested in July, 1920, and the desire to marry again. But why he tried to murder Mr. Martin is almost inexplicable, unless one supposes he had acquired a sort of tolerance towards arsenic in other people's systems. However that may be, it was his attempt to do it again that aroused suspicion in the local doctor's mind, and from that time onwards "the slow but certain wheels of the criminal law began to revolve," until after a nine days' trial before Lord Darling at Hereford, and a four days' hearing in the Court of Criminal Appeal, Armstrong paid the penalty. The verbatim report of the proceedings is well arranged and accurately reproduced, and the introduction most readable.

HUMAN INHERITANCE.

THE book on human inheritance[8] by BAUR, FISCHER, and LENZ, now in its third edition, remains a comprehensive and authoritative account of the facts of organic inheritance in man and of the implication of these facts. There are many slight modifications and a few additions in this new edition, as is to be expected in view of the rapid advances that are being made in genetical science and in our knowledge of the biology of man. The increase in the number of references bears witness to this. The part written by Baur shows less change than the others for the reason that even at the time of the last edition all the relevant general principles of genetics had been enunciated. The section for which Fischer is responsible contains many new data, particularly concerning the mode of inheritance of the physiological characters. Lenz, in his section, gives many more pedigrees, and the genetic basis of such traits as the criminal disposition is now discussed. A section on the biometrical methods of analysis has been added. The amazing activity of the American school of psychologists is reflected in this book, for there is a noteworthy addition to the discussion of racial mental differences. Moreover, far more attention is given to the results of the examination of twins, and emphasis is laid upon the urgent need for an active study of inheritance in such material.

The reader will find the book distinctly discursive, and may have to dig deep before he finds the treasure he seeks. However, the treasure is there for the seeking. It is a book of reference rather than a manual, but it would be well if every medical man at some stage of his career should make himself fully acquainted with the facts proving that organic inheritance plays an exceedingly important part in the maintenance of health or the production of disease. The examination of a patient commonly should include a study of his pedigree. In the reports on hospital patients required to be made by clinical clerks or their equivalents for the physicians during the later part of last century, much more attention was given to the history, family and personal, than seems to be the case at the present day.

NOTES ON BOOKS.

THE little book on serum sickness[9] by Drs. R. J. WEISSENBACH and GILBERT-DREYFUS contains a brief historical introduction, and is divided into five principal parts devoted to clinical questions, etiology, pathogenesis, prophylactic and curative treatment, and prognosis. In their clinical study the writers distinguish the following varieties of reaction: (1) early general reaction, (2) late general reaction, (3) local reaction in the skin, meninges, and joints, (4) focal reaction, as exemplified in the late subaxillary adenitis in diphtheria and the meningeal reaction in cerebro-spinal meningitis. Special attention is given to the atypical forms of serum sickness which have lately been described, such as amyotrophic paralysis, generalized adenopathy, orchi-epididymitis, pleuro-pulmonary manifestations, symptoms of suprarenal insufficiency, and affection of the alimentary canal and its adnexa. In their discussion of the pathogenesis of serum sickness the writers are inclined to attribute the early phenomena to colloidoclasia, while the late symptoms they regard as of toxic origin. With rare exceptions the prognosis of serum sickness is favourable. According to the latest American statistics only one death occurs in 75,000 injections. Hardly any notice is taken of the work of other than French writers. It is therefore not surprising to find that no allusion is made to the prognostic value of a well marked serum reaction occurring in diphtheria, to which several writers in this country have drawn attention.

A small French book on laboratory methods for the detection of tuberculosis[10] is a handy volume, obviously written by an experienced laboratory worker, which describes the many chemical and microscopical tests which may be used in the diagnosis of tuberculosis. The first part of the book describes direct methods, such as examination of stained films, inoculation of susceptible animals and cultural technique. The second part reviews indirect methods, such as serological tests, cytology, and chemical investigations. It is essentially a practical book, and will serve a very useful purpose.

Dr. PIERRE HULLIGER of Neuchâtel in Switzerland has written a little book[11] the main object of which appears to be to laud the treatment by chemico-therapy which he practises at the Mont-Riant clinic. Incidentally he examines treatments in high-altitude sanatoriums, at the seaside, by tuberculin, serotherapy, and pneumothorax, and finds them all wanting. Our object, he says, must be to cure consumptives "on the plain and in our towns." This, he thinks, can be done by the subcutaneous injection of a mixture of salts of copper, mercury, manganese, silver, tin, and arsenic. The injections produce a feeling of lassitude and sometimes a slight rise of temperature, but no local reaction; they cause, however, an intense congestion of all the tuberculous foci in the organism. Sometimes, though rarely, "reactivation" of latent foci is caused; and this, says Dr. Hulliger, has given him a "bad press." He finds the phenomenon useful, since it shows up the disease even when hidden in obscure corners of the body. Probably the only usefulness of Dr. Hulliger's book is in reminding us that none of the treatments for tuberculosis are very satisfactory as cures; but the directions he gives to patients in the matter of general treatment are sound and simply stated.

The seventh edition of *Hewat's Examination of the Urine*[12] has been revised by Dr. G. L. MALCOLM-SMITH. In addition to examination of the urine, sections are allotted to the investigation of the blood, sputum, gastric contents, and the faeces, and in this new edition sections have been added on fractional gastric analysis, renal efficiency tests, and examination of the cerebro-spinal fluid. This handy book, while insufficient as a guide to the more elaborate chemical investigations, contains the simple tests which are in common use, and will probably be even more popular than its predecessors.

PREPARATIONS AND APPLIANCES.

Collo-Calamine.

COLLO-CALAMINE is an impalpably fine powder having the composition of calamine. Calamine, as is well known, is native carbonate of zinc prepared for medical use by elutriation. It is not mentioned in the current *British Pharmacopoeia*, but was official in that *Pharmacopoeia* of 1885, and is still extensively used as a cutaneous remedy. Its power of beneficial action depends upon the extent of surface possessed by a given quantity, or the degree of fineness into which the particles are subdivided. Collo-Calamine, which is placed on the market by the *British Drug Houses*, is of a fineness much beyond the ordinary. As suggested by the name, it is almost colloidal. It ought accordingly to give satisfaction to prescribers who prefer, as many do, the natural substance to the artificial zinc carbonate of the *Pharmacopoeia*.

A Water Heater.

A very simple water-heating appliance has been brought out by Triggs, Demaine and Co. (181, Queen Victoria Street, London, E.C.), under the name of the "Fox" water heater. We have had the opportunity of seeing it in action, and for cleanliness, simplicity, and efficient working it suggests an admirable fitting for the surgery. It is a storage apparatus, cold water automatically replacing hot water drawn off, and has two gas burners which, also automatically, are cut down to small jets when a maximum temperature is reached. Hot, tepid, or cold water as required can be drawn from the same tap by moving an indicator. When the hot water is drawn off the small jets expand to a full flame until the reservoir reaches its maximum capacity again. It appears to be free from fumes or smell, and certainly obviates the need for the use of matches or the manipulations of interlocking taps. The smallest type has a capacity of 1¼ gallons, but the apparatus is made also with a capacity of 25 gallons for baths and hospital use. It is undoubtedly a very convenient type of water heater.

A Combined Ultra-violet Radiation Apparatus.

The difficulty of a choice of sources of ultra-violet radiation has been met by the Medical Supply Association, Ltd. (167-185, Gray's Inn Road, London, W.C.), in the shape of what they call their "Trinity" apparatus, which combines on one stand the three types of lamps now employed—namely, the quartz mercury vapour lamp, the tungsten arc lamp, and the carbon arc lamp. The three are provided at only slightly more than the cost of the single model, and the saving of floor space is obvious. The apparatus also permits of two lamps being run simultaneously, and of local or general irradiation from each lamp. It is designed for use on the direct current, but an electrolytic arc lamp rectifier is provided for an

STEPHEN HALES, D.D., F.R.S.,

PHYSIOLOGIST AND BOTANIST.

CELEBRATION AT CORPUS CHRISTI COLLEGE, CAMBRIDGE.

THE Master and Fellows of Corpus Christi College, Cambridge, celebrated the anniversary of the birth of Stephen Hales, on Thursday, June 16th, by entertaining a large party within the College. During the afternoon the Parker collection and the plate belonging to the College were displayed. The Parker collection the College owes to Matthew Parker, who was Archbishop of Canterbury from 1559 to 1576; he had previously been Master of Corpus Christi College, and gave to it many manuscripts, books, and plate. To the University library he gave also manuscripts and books. At seven o'clock Dr. A. E. CLARK-KENNEDY, Fellow of the College, and assistant director of the medical unit at the London Hospital, gave a dissertation in the chapel. The guests were then entertained to dinner in the Hall of the College, and afterwards the Master and Mrs. Pearce held a reception in the Lodge.

STEPHEN HALES, D.D., F.R.S.
(From a mezzotint in the collection of Dr. Arnold Chaplin.)

At the time Stephen Hales lived (1677-1761) modern science was in its cradle at Cambridge, and if we would review all that has been accomplished in the cause of science in the University down to the present time, it is to that period we must turn for a knowledge of the beginnings of the wonderful movement which bore such fruit in later years. It is not too much to say that the birth of science at Cambridge was due to the mighty influence of that glory of the University, Isaac Newton, who planted there the experimental method in science. Since his day Cambridge has been under that *domination*, and Hales was one of the men who carried on the splendid tradition. But in this Hales was not alone at Corpus. Dr. Clark-Kennedy mentioned the close association existing between Hales and Dr. William Stukeley, who was a fellow student at Corpus Christi College, and from the diary and letters of Stukeley, published by the Surtees Society, we may learn how ardently the two friends pursued their inquiries into science by the experimental method. As Dr. Clark-Kennedy reminded his hearers, they rambled together over Gog-Magog hills and Cherry-Hinton Moor collecting simples, hunting for fossils, and catching butterflies, "having contrived an instrument for taking them." Together they studied anatomy, dissecting dogs and other animals; and attended the public lectures of Vigani, first professor of chemistry, and witnessed the "chymical" experiments he performed in the rooms over the Gateway of Trinity, which had been the laboratory of Sir Isaac Newton. Hales applied himself also to astronomy, and, having acquired a "perfect knowledge of the Newtonian system," contrived a mechanical model to demonstrate the movements of the planets. Hales was appointed to the parish of Teddington, Middlesex, at the end of 1708, and although he afterwards received other preferments, he continued for the most part to reside there until his death on January 4th, 1761, in his 84th year. It was there, as Dr. Clark-Kennedy said, that he made experiments of fundamental importance, on the circulation of the blood, the flow of sap, the chemistry of respiration, and the growth of bone; and "by his work on ventilation established one of the first principles of preventive medicine." By repeating many of Robert Boyle's experiments he had learnt the value of the experimental method, and quoted with approval the dictum that "it is not within the compass of human understanding to assign a purely speculative reason for any one phenomenon in nature."

Stukeley in after-life became famous as a physician and an antiquary, and it was owing to his activity that the *Antiquarian Society was re-established*. But before them two members of Corpus Christi College—William Briggs (1642-1704) and Edward Tyson (1650-1708)—had contributed to the advancement of science. William Briggs, physician to St. Thomas's Hospital, was one of the first in this country to write on the anatomy and the functions of the eye. He it was who taught Newton all he knew about the eye, and first enunciated the theory of vibrations as an explanation of the phenomena of nervous action, while Edward Tyson was one of the first in this country to study comparative anatomy, and the beautiful drawings he made to explain the anatomy of various animals form one of the most treasured possessions of the College of *Physicians*. In later times two other members of Corpus Christi College attained distinction in medicine and science. Dr. David Pitcairn (1749-1809), physician to St. Bartholomew's Hospital, was the first to point out the close association between rheumatic fever and heart disease; and, coming down to our own days, Dr. Bond, the Regius Professor of Physic at Cambridge from 1857 to 1882, filled that chair with dignity and distinction. It will be seen, therefore, that Corpus Christi College, although only thirty-seven members of the college graduated in medicine from the year 1500 to 1850, produced five men who all left their mark upon the profession they adopted—surely a record of which the college may be proud. During the same period of three centuries and a half there were some fifteen hundred medical graduates from the whole University.

As evidence of the activity of the scientific spirit in Cambridge when Hales was in residence at Corpus, attention may be drawn to the foundation of chairs in various sciences at about that time. Thus the chair of chemistry was founded in 1703, the Plumian chair of astronomy in 1707, that in anatomy in 1707, in botany in 1724, and in geology in 1731. The foundation of these chairs was the beginning in the University of that study of natural sciences which has produced such notable results in modern times.

THE DISSERTATION.

In the course of his dissertation, to some of the earlier passages of which we have already referred, Dr. Clark-Kennedy said that to Hales—*primarily* a biologist but trained as a physicist—the circulation of the blood, discovered rather less than a century before him, must have presented a fascinating study, and his first scientific endeavour was to make a complete quantitative investigation of the dynamics of the circulation.

The Circulation of the Blood.

"Since we are assured," Hales wrote, "that the animal fluids move by *hydraulic* and *hydrostatical* laws, the likeliest way therefore to succeed in our inquiries into the nature

of their motions is by adapting our experiments to those laws." He therefore devised his "haemastatical" method, which consisted of the application of the principle of the manometer to animal physiology, and performed a vast number of experiments of great technical difficulty, not in a well equipped laboratory, but in the parsonage at Teddington. By tying tubes into the arteries and veins of living animals he was the first man to record blood pressure. In so doing, not only did he advance our knowledge of cardio-vascular physiology by a definite and important step, but at the same time laid the foundation of a valuable clinical method in the study and diagnosis of disease. For this performance Hales is justly famous. But in addition he investigated almost all the mechanical aspects of the circulation, and made a more complete study of cardio-dynamics than even Lower had done before him. His description of this branch of physiology is so complete, so quantitative, so essentially modern in all its tendencies, that it reads like a chapter in a present-day textbook. By recording the pulse rate during life, and then injecting the heart with wax, he computed the circulation rate in horses, cattle, deer, and dogs. He showed that in large animals the blood flow is relatively less than in small, but, in the absence of a true conception of respiration and metabolism, he failed to realize the significance of this result. He estimated the actual velocity of the blood stream in the different arteries and veins. He measured the velocity of the blood in the tissue capillaries by observation with a microscope, and compared it with indirect calculations of the velocity of the blood in those of the lungs. Studying blood flow in the tissues, he estimated the capillary blood pressure and demonstrated vaso-constriction by cold, vaso-dilation by heat. Lastly, by pointing out that the heart responds to increased venous return by increased systolic output, he laid the foundation of the conception now known as "Starling's law."

Movement of Sap.

Hales was essentially a comparative physiologist. He alternated between experiments on plants and experiments on animals. While endeavouring to stop the bleeding of an old stem of a vine, which was cut too near the bleeding season, it occurred to him to make the following experiment.

> Having tied a piece of bladder over the transverse cut of the stem I found the force of the sap did greatly distend the bladder, whence I concluded, that if a long glass tube were fixed there in the same manner, as I had before done to the arteries of several living animals, I should thereby obtain the real ascending force of the sap in that stem, which succeeded according to my expectation; and hence it is that I have been insensibly led on to make farther and farther researches by variety of experiments.

Applying this method, he found the sap pressure in the vine in the bleeding season to be "five times greater than the force of the blood in the great crural artery of a horse; seven times greater than the force of the blood in the like artery of a dog; and eight times greater than the blood's force in the same artery of a fallow doe."

Growth in Plants and Animals.

Hales also devised the method of studying the growth of plants by marking the stems and leaves at equal intervals, and was led on to apply a similar method to the growth of bones. He wrote:

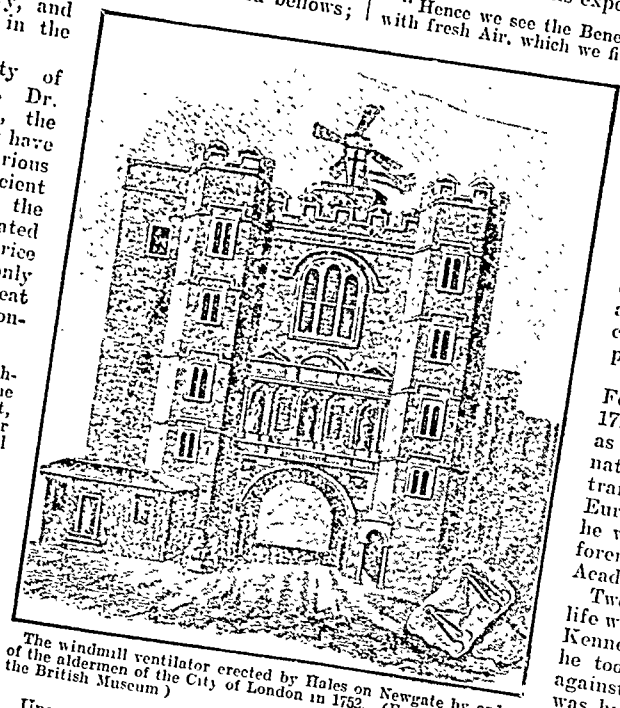
> "The tender ductile bones of young animals are gradually increased in every part that is not hardened and ossified; but since it was inconsistent with the motions of the joints to have the ends of the bones soft and ductile, as in vegetables, therefore nature makes a wonderful provision for this at the glutinous serrated joining of the heads to the shanks of the bones, which joining, while it continues ductile, the animal grows; but when it ossifies, then the animal can no longer grow: as I was assured by the following experiment, viz.: I took a half grown *chick*, whose leg-bone was then two inches long; with a sharp-pointed iron, at half an inch distance, I pierced two small holes through the middle of the scaly covering of the leg and shin-bone; two months after I killed the *chick*, and upon laying the bone bare, I found on it obscure remains of the two marks I had made at the same distance of half an inch: so that that part of the bone had not at all distended lengthwise, since the time that I had marked it; notwithstanding the bone was in that time grown an inch more in length, which growth was mostly at the upper end of the bone, where a wonderful provision is made for its growth at the joining of its head to the shank, called by anatomists *symphysis*."

This experiment, usually attributed to John Hunter, born in 1728, was actually performed by Hales some years before that date.

Hales's interest was deflected to the chemistry of respiration by an accidental observation that bubbles of air ascended with the sap.

Chemistry at that time, Dr. Clark-Kennedy said, was an empirical and largely speculative study. The conception of chemical elements had not yet been formed, and chemical substances were still described and classified according to their properties. In 1660 Robert Boyle had demonstrated that a candle became extinguished, and that an animal died, when placed in an evacuated vessel. Nine years later Lower discovered that blood takes up air. At about the same time Mayow (who was a Fellow of All Souls' College, Oxford, and practised medicine in Bath) came to the conclusion that it was not the whole air, but a part of it only, which was essential for respiration and combustion alike; this fraction he called the *spiritus nitro-aereus*. Thus Mayow virtually discovered oxygen, and laid the foundation of a true conception of animal heat, when he supposed that this arose from the combination of his nitro-aereal spirits with the sulphureous particles of the blood. Mayow clearly realized that a part of the air went into combination with the blood, but he failed to realize that anything came out. Mayow's work, however, received but scant attention, and thirty years later knowledge was put back over a century when Stahl introduced his phlogiston theory. According to this conception, which dominated biology and chemistry for over a hundred years, when a substance burned, phlogiston departed from it. The body suffered a loss, it became dephlogisticated. Stahl, rejecting the idea that animal heat was due to chemical action, returned to the old view that it arose from friction of blood in the vessels, while his pupil Haller, writing only a few years before Hales died, denied that air entered into combination with the blood, so completely had the work of Mayow and Lower been neglected. Not till 1754 did Black deal his death blow to the phlogiston theory when he prepared carbon dioxide, and not till twenty years after Hales's death did Lavoisier enunciate the true principles of respiration, combustion, and animal heat.

Applying his "statical method," Hales demonstrated that plants absorb considerable quantities of "air." By distilling vegetable substances he showed that plants contained "air." He came to the conclusion that "air" enters into the constitution of plants, and that an important function of the leaves was absorption of this form of nourishment. "It is by this amphibious property of air," he wrote, "that the main and principal operations of nature are carried on"; and then came this significant sentence—"May not light also, by freely entering the expanded surfaces of leaves and flowers, contribute much to the ennobling the principles of vegetables?" Again, as Michael Foster pointed out, Hales was the first man to give a clear enunciation of the existence of gases in both a combined and free state.



True to his comparative physiology, from absorption of air by plants he turned his attention to respiration in man. He repeated Mayow's experiment on the respiration of animals. Mayow had shown that animals absorb a part of the air they breathe, but Hales carried things a step further when he came to the conclusion that respiration in some way modifies the properties of the air left over so as to make it unfit both for life and for combustion. Thus he was led to experiment on himself, and to perform the first rebreathing experiment. A little later he devised an apparatus with inspiratory and expiratory valves so arranged that the expired air had to pass through diaphragms of cloth before being inspired again, and observed that when these diaphragms were moistened with a solution of "sal tartar," and then replaced, rebreathing could be continued for five to eight minutes. Moreover, the diaphragms increased in weight to a greater extent than he could account for by absorption of water only. If Mayow can be said to have discovered oxygen, surely Hales

described carbon dioxide! Throughout Hales's writings here is no mention of the phlogiston theory. By this silent refusal to follow Stahl he kept alive the spark of truth that Mayow had lit, to be rekindled more than a century later by Black, Priestley, and Lavoisier. But if only he had followed Mayow a little more literally, and conceived, as Mayow had, of different kinds of gases, instead of one "air" with variable properties, he might well have arrived at a true conception of respiration. Be this as it may, Hales's researches on respiration had a great practical outcome in his work on ventilation.

Ventilation.

Incidentally, Dr. Clark-Kennedy mentioned that Hales invented methods of purifying water and of salting animals whole, and advocated the addition of acid to keep fresh water sweet, and the use of burning brimstone for the prevention of "weevil and meggots" in ship's biscuit, and for preventing the rise and spread of "infectious distempers." The first-fruit of his study of ventilation was a method to be applied to ships by means of hand bellows; it was used in some of the ships of the Royal Navy, and also in vessels engaged in the slave trade.

In entering the City of London from the west, Dr. Clark-Kennedy continued, the traveller of those days must have been confronted by a curious spectacle. Newgate, the ancient gate of London built by the executors of the celebrated Richard Whittington, thrice Lord Mayor of London, and only partially destroyed in the Great Fire, had been rebuilt with considerable magnificence.

The windmill ventilator erected by Hales on Newgate by order of the aldermen of the City of London in 1752. (From a print in the British Museum.)

"It consisted of a carriage archway in the centre; on the side, the footpath was continued through it, which supplied a shelter for two or three old women, who fried small sausages for sale; and in the centre of it was an entry to the chief prison of the city: the mendicant prisoners for debt stood within the iron grated door, vociferating their constant supplication for benefactions to a leathern bag which they drew in as often as it was touched; the upper chambers of the buildings constituted the prisons for felons, for whom a door was opened on the South side adjoining the old wall, and it was from this door that the malefactors were received into the cart for their last journey to Tyburn. Upon the summit was a machine for air, invented by Dr. Hales."

In 1750 a tragedy had occurred during the trial of malefactors at the Sessions House in the Old Bailey. The Lord Mayor, two judges, and a total of sixty persons had died of the gaol distemper, communicated to them by the felons from Newgate. The aldermen of the City of London, naturally seriously alarmed, consulted Hales, and decided to install ventilators in Newgate to be worked by a windmill erected on the leads. When the system was complete, Hales made a tour of inspection of Newgate, and rejoiced to see the ventilators "drawing like large heavy lungs at the rate of seven thousand tuns of foul air per hour out of the different wards of the prison." Hales's ventilators were also installed at the prison in the Savoy (London), in the gaols at Northampton, Shrewsbury, Winchester, Maidstone, Bedford, and Aylesbury; in the London small-pox hospitals, at St. George's Hospital, and in hospitals at Durham, Winchester, and Bristol, and even at Naples. They were introduced also into the naval and military hospitals and prisons at Gosport, Portsmouth, and Plymouth.

Wherever Hales's ventilators were installed the air in the wards is said to have been rendered much purer, and the mortality among the inmates from the gaol distemper considerably reduced. But typhus is due to the bites of infected lice, and not to foul air, as Hales supposed. No amount of ventilation, however perfect, could have abolished the gaol distemper. Hales's bellows ventilator has gone. Hospitals and prisons are so built in these days that mechanical ventilation is seldom necessary. But his principle of the forcible propulsion of air still persists, and adequate ventilation remains one of the first principles of preventive medicine. Hales must therefore stand, not only a great biologist, but one of the pioneers in public health.

In 1756 Hales performed his last experiment. He placed an equal number of gudgeon in two pails of pond water; the water in one was ventilated with air, the water in the other allowed to remain stagnant. The fish in the former remained well, but those in the latter, the unventilated water, soon "turned sick, came up for air and showed uneasiness, turned belly upwards, and then died." He commented on this experiment as follows:

"Hence we see the Benefit of frequently replenishing the Water with fresh Air, which we find is necessary not only to preserve the Life of Land Animals, but also of Fish; as also the Use of their Gills, to spread in thin Sheets fresh Supplies of Water, that they may the better come at the Air in the Water; for which Purpose both Sides of their Gills are furrowed with many fine Furrows, thereby to enlarge their Surfaces."

So at the age of 79 he returned from his applied science to his comparative physiology again, and after the lapse of forty years completed his long series of experiments on respiration.

Hales had been elected a Fellow of the Royal Society in 1718, and later his reputation as a scientist became international. His books had been translated into all the chief European languages. In 1753 he was elected one of the eight foreign members of the Royal Academy of Sciences in Paris.

Two other incidents in Hales's life were described by Dr. Clark-Kennedy; the one was the share he took in warning the public against gin drinking. The other was his unfortunate consent to be one of the sponsors of Joanna Stephens, to whom Parliament was induced to give £5,000 for divulging her method of dissolving the stone.

Though Hales was so interested in experimental research he did not neglect his duties as parish priest of Teddington, but served the parish with the same energy and zeal. He made the women of his parish do public penance for irregular behaviour; he induced the lord of the manor to enlarge the churchyard; he added an aisle to the church, and erected a new tower with a big bell, meeting part of the expenses out of his own pocket. He also arranged for a new parish water supply.

Of his character one of his contemporaries said: "He possessed a native innocence and simplicity of manners which the characters of other men and the customs of the world could never alter."

Stephen Hales died at Teddington on January 4th, 1761, in the eighty-fourth year of his age. His monument stands in Westminster Abbey, but his body lies buried, according to his own wish, under the tower which he had himself built for the church he had loved so well. The inscription on the stones of the floor of the tower records the simple facts of his life and death, but there is no epitaph written on his grave. To-day, however, 250 years after his birth, let us adapt the words John Wesley wrote of him. "How well did Science and Religion agree in this man of sound understanding."

British Medical Journal.

SATURDAY, JUNE 18TH, 1927.

THE ECLIPSE.

A TOTAL eclipse of the sun is, by the common consent of all history, an amazing phenomenon. It has not only amazed and filled its beholders with an undefinable fear; it has sometimes caused them to mend their ways, and even brought a war to an end. Among the fierce denunciations by Amos of national evils and his forebodings of the calamities that would follow, the climax of horrors is reached in the lines: "And it shall come to pass in that day, saith the Lord God, that I will cause the sun to go down at noon, and I will darken the earth in the clear day." It is supposed that this is a reference to the eclipse of 763 B.C., which was total at Nineveh, and of which there is a record in a cuneiform inscription. The old sense of fear died hard. In 1715 Halley thought well to warn his fellow citizens when a total eclipse was due to be seen in this country, thus: "The like eclipse having not for many ages been seen in the southern parts of Great Britain, I thought it not improper to give the publick an account thereof, that the sudden darkness wherein the stars will be visible about the sun may give no surprise to the people, who would, if unadvertized, be apt to look upon it as ominous and to interpret it as pertaining evil to our sovereign lord King George and his government, which God preserve." But to know what is the meaning of this awful dousing of the sunlight is not to diminish the magnificence of the spectacle, any more than the knowledge of the causation and the frequent experience of thunder lessen its impressiveness.

The sun each year appears to complete a "great circle" of the heavens. The moon makes its circuit every month. If the circles were coincident there would be a monthly eclipse every new moon, but they do not coincide, being inclined to one another at an angle of some five degrees. These circles must cut one another at two opposite points, the "nodes." When the new moon is at or near one of these nodes it intervenes between sun and earth, and an eclipse is seen somewhere. The sun is vastly larger than the moon, but the moon is much nearer the earth, and the relation of the two conditions is such that the smaller moon can completely blot out the greater sun, and cause the total eclipse. When the sun is thus obscured its radiance is revealed to the eye in an appearance that has no equal in luminous phenomena. There is the gradually increasing darkness, the shining of the stars, then around the black disc of the moon blaze out vast ruddy flames of the sun's conflagration, and the pearly hues of the "corona" are flung far into the sky. One moment, and it is gone. The light returns.

It is 200 years since this was seen in any part of these islands. If only the sky be clear of clouds, on the morning of June 29th it will be seen again. The conical shadow of the moon will sweep across North Wales and the northern counties of England from Criccieth to Hartlepool, travelling the couple of hundred miles in a couple of minutes; and observers of total eclipses in other parts of the world say that it can be seen, even though the sun be obscured, by anyone who will resolutely turn his back to the sun. At any one place on the line of totality the darkness will last for a score of seconds. Since the apparent movement of the sun is from the north-eastern sky, the shadow will come out of the south-west, and is due to approach from the Atlantic at 5.23 a.m. Greenwich mean time, or an hour later by our summer-time clocks. It takes the line of Criccieth and Abergele in Wales; Southport in Lancashire; Settle, Richmond, and Hartlepool in Yorkshire, where it is due to pass away at 5.25. Fifteen miles on either side of this line the eclipse will be nearly total. A glance at the map will show what extreme variations of terrain it will traverse—crowded industrial centres and moorlands almost uninhabited.

The old-time fear of the eclipse has gone, and for that very reason there is the more cause for fear of carelessness in viewing it. The warnings against the risk of "eclipse blindness" are no mere old wives' tales. The risk is real. It is not exceptional; it is the same as the risk to the sight of looking at the sun on any day that it shines, but this is so difficult that few, save children, attempt it. There is a like risk in the electric arc, and, to a lesser extent, in looking at a powerful gas-filled glow lamp. But it is a risk that can be easily escaped. There are two ways whereby we may protect the eyes. Both are familiar. In any fog we can look at the red disc of the sun with impunity. Properly fogged glass will be a protection. We can look at the sun at midday through a narrow crack between our fingers with comfort, so a pin-hole screen will furnish good protection. Of the two the fogged glass is the better. There is less risk of careless use than with the pinhole, for that may vary in size, and its size will vary according to its nearness to the eye—the closer it is held the larger the hole becomes, and the less protection it will give. Not every fogged glass will give protection. The fogging should be enough to allow one to look with open eyes at an electric arc a foot away from the eyes, or with equal ease at the filament of a gas-filled electric lamp of high power. One should be able to view the filament as a fine reddish pattern without glow, and without feeling the least suggestion of after-effect in one's eyes when ceasing to look at it. A perfect glass is made by using together two pieces of coloured glass, one red and the other green; each should be of such depth of tint as will only allow light of its own colour to pass—red through the red glass and green through the green. It follows that if one tries to look through the two glasses together nothing will be seen, the window will be black; but there will be sufficient incompleteness in the saturation of colours in the glasses to allow intense illumination to pass, and through these two glasses the sun at the zenith is a clear pinkish disc, and the most brilliant electric arc a pink spot. The red and green glass of the once familiar hall window of an early Victorian house would make an admirable protection.

There are a number of specially prepared screens on the market. Two have been submitted to us. One is a film marketed under the name of "Eclipsia" by Messrs. Hamblin; it has been worked out by Dr. Judd Lewis, and limits the spectrum by cutting out the violet end completely as well as by reducing illumination. It is a simple and effective contrivance, and costs only a small sum. Another is a screen furnished with a couple of optically ground dark glasses, issued by Messrs. C. Baker of High Holborn; it also is inexpensive and effective. The film has a notch for the nose, but the glass screen needs to have its mount cut. Many will use opera-glasses or telescopes. With

these it is imperative that the screen should be easily removable and as easily reaffixed. It should not be a fixture, for clear glass is needed to view the actual eclipse, but the reapplication of the screen is imperative immediately the sun begins to show again.

There are two reasons for this care. The temporary reason is that if the sun be looked at unveiled before the eclipse the eye will be so exhausted that the wonder of the eclipse will not be seen, and the labour of the journey will be unrewarded by a sight of the spectacle. There is, however, a much more serious reason. Exposure to brilliant excessive light causes actual injury to the retinal elements of the eyes, and this may be permanent, causing a central scotoma or blind spot. Fundus changes due to such exposure are well known; there are minute spots of degeneration. There is therefore every reason for members of our profession to inculcate care in viewing the eclipse, the more especially since we understand that arrangements have been made to take large numbers of school children to places on the line of totality so that they may see the phenomenon. Children are more susceptible than adults to the risks of damage to the eyes by excessive light, for the lenses of their eyes are clear and translucent, whereas adult lenses are more or less dense and yellow. The school authorities responsible for these expeditions should be forearmed for the occasion; accidents would be nothing less than "culpable negligence." Totality lasts but twenty seconds, and is followed by the blinding flash of the uncovered sun.

GENIUS AND THE AMERICAN PEOPLE.

In recent years Americans have eagerly pursued their pasts, seeking ancestry that should endow them with genetic reasons for their successes. Latterly, however, they have turned their eyes towards the future, seeking their genetic destiny.[1] There is almost humour in the thought that it should be an American who perforce must teach that great democracy that men are not born free and equal, but bound and unequal, that ability cannot be the birthright of every individual, but that for genetic reasons it is a familial affair. The wealth of a nation, spiritual and cultural, is ultimately determined by the number of its superior families, rich in possessions that social legislation may depreciate but can never destroy.

For the student of human biology the United States is a vast and fascinating experiment. It is not yet a race not yet a nation. A great proportion of the individuals who have played their parts in the making of the nation that is to be have not been, it is safe to assume, the ablest specimens of the peoples to which they belonged. Success of a kind was easier of attainment there than in the older countries, for there was plentiful scope and abundant recompense for arduous labour. There has been, up to now, a huge hinterland into which the relatively incompetent could always retreat, so that in the past selection has not operated at all scathingly. Into this hinterland, too, would go some of the most competent, fired by the joys of grappling with the bigness of Nature, to spend their efforts in creating and not in conserving. Acquisition of material possessions has been so simple that a man held property lightly, gambled with fate, won and lost, and won again. All this is changing rapidly, and America is tending to become conservative. Acquisitions, material and spiritual, are now being valued and conserved.

The individual in his self-expression is largely a reflection of his environment. Ability, when possessed, is polymorphic. There is every reason to think that there has gone to the United States germ plasm potentially far more valuable to that country than were the individuals who bore it to their generations. There is every reason to hold that in America to-day there are the genetic components of all the qualities that make for human greatness as well as for human wretchedness. Changing social conditions, the shuffle and deal of marriage, will, it may be assumed, ultimately lead to the replacement of anthropologically the most mixed people the world has ever known by a nation with a past and with a point of view.

It is not to be expected that as yet there can have been an American genius, though, of course, there is no reason why a genius should not have immigrated in the form of either a gamete or a zygote into the United States. There have been and are great men there, but they are all products of the Old World. Political severance does not involve a discontinuity in the stream of germ plasm. When the United States has become a nation, then a typical American genius will doubtless appear. The possibilities of this are immense, for the United States has drawn largely upon stocks that have produced genius. Any sufficiently populous country, in the absence of mutation among its population, and in the absence of immigration, can be expected to reproduce the great men of its past. The elements of greatness, when once present in a people, are not easily lost. In the case of a country like America the chance of a really great man appearing depends upon the variety and number of genetic components brought into that country by immigration.

In America search is being made for the constituents of greatness. As a corollary to this, inquiries are being instituted to determine how far genius is due to organic inheritance, to social inheritance, and to education. When this is known it will be possible to guide incipient genius to full expression. The early mental traits of a number of men of acknowledged pre-eminence have been examined, every remaining scrap of their correspondence has been studied, and to each of these men an "intelligence quotient" has been ascribed. The method of assessing potential brilliance is necessarily faulty. The data upon which the estimates are made are incomplete, and in many instances cannot be regarded as truly representative, and no control series relating to the early mental traits of mediocre men is available for comparison.

However, these estimates, faulty as they are, are taken as standards of the measure of developing genius, and against them are placed the records of 600 gifted children, selected by the teacher and sifted through a Stanford-Binet psychological test out of a quarter of a million Californian school children. These children and the parents were examined in almost every conceivable way, questionaries were rained upon them, anthropometrical and medical overhauling was thorough, probings as to interests, character, personality, and so forth were deep and searching, and there can be no doubt that the very best use was made of the tools which at the present are available for the analysis of the individual. The difficulty that lies in the way of a ready acceptance of the value of these tests is very real. There is as yet no unanimity among psychologists themselves as to which system of psychological analysis is the best. Moreover, we cannot be sure in the present state of knowledge that

[1] *Genetic Studies of Genius.* Edited by Lewis M. Terman. Assisted by several contributors. In two volumes. Stanford University, California: Stanford University Press; London: G. G. Harrap and Co., Ltd. 1926. (9½ × 6½, Vol. I., pp. xiii + 648, 35 figures; Vol. II, pp. xxiii + 842, 10 figures, 49 tables. 21s. net each volume.)

potential genius would not slip through this sieve of the intelligence quotient test. Again in this particular investigation no control series was studied.

But this much can be said and should be said: This study is the most comprehensive and the most reasonable that has yet been made. It represents years of tremendously hard and careful work that will not be wasted. Imperfect as it is, it will serve its purpose if only by emphasizing the need for refinements in the existing methods for the analysis of personality. Its greatest value, however, lies in the fact that it demonstrates beyond all doubt that nations are taking stock of their most valuable possession—the germ plasm of their people; that they recognize that for the fashioning of the leaders by whom further civilization shall be guided the greatest care must be shown, not only in the choice of the methods of education, but also of the material to be trained.

THE HARVEY TERCENTENARY.

NEXT year, under the auspices of the Royal College of Physicians, will be celebrated in London the tercentenary of the publication of Harvey's epoch-making book, the *De Motu Cordis*, in which, by convincing experiment and accurate reasoning, he demolished for ever the thousand-year-old theory of Galen concerning the circulation of the blood, and in its place erected on a sure foundation his theory, which has been accepted by the world ever since. As we have already intimated, the plans of the Royal College of Physicians for the celebration of the tercentenary of this event are comprehensive, and no pains have been spared to make the function fully worthy of the great occasion. Delegates from all countries will gather in London to offer their tribute to the memory of the first and greatest of physiologists. Sometimes this country has been held to be unmindful of the anniversaries and centenaries of the conspicuous work of her great sons, but in this case it is hoped that the programme in the contemplation of the Royal College of Physicians will remove that reproach, and will show that we hold in deepest honour and reverence the memory of William Harvey, one of whom this country may well be proud. But while we are celebrating in London in befitting form the great work of Harvey, we should turn our thoughts to the quiet little country church at Hempstead in Essex, where the mortal remains of Harvey repose in a sarcophagus which in 1883 was provided by the Royal College of Physicians—an act of piety it owed to the memory of its most distinguished Fellow. The sarcophagus is now safe from the ravages of time, but the church in which it is placed is in a parlous state. The church tower has fallen down, and of the five bells one, the tenor, was shattered by the fall. The other four escaped injury, and are hung in a shed in the churchyard. A comparatively small sum of money would rebuild the tower, and render Hempstead Church a fitting abode for the great Dust it shelters. Already some money has been obtained. Surely, while we hold Harvey in reverence, funds will be forthcoming for the accomplishment of this duty of all those who venerate his name. The honorary treasurer of the fund is Mr. A. W. Ruggles-Brise, Spain's Hall, Braintree; cheques should be crossed Barclays Bank, Saffron Walden.

THE VALUE OF SCIENTIFIC THEORY.

SIR J. J. THOMSON, O.M., in the tenth Silvanus Thompson Memorial Lecture which he delivered before the Röntgen Society last Tuesday evening, made it evident how tentative and hypothetical is the whole subject of the structure of the atom. He likened the problem confronting the physicist to that of an engineer who is called upon to design a machine, but from whom dimensional and other requirements are withheld. Equally able engineers in such a case would make quite different guesses. But it did not follow that the tentative working hypothesis was without value. Scientific theory, he said, was not a creed, but a policy—it was something which should direct and suggest experiment. The simple working theory which presently turned out to be untenable might nevertheless have made for progress in a way not possible to the more elaborate theory which, while it was less open to objection, did not stimulate inquiry. Until we had much more experimental knowledge, said Sir Joseph Thomson, tentative theories must content us. What was wanted was an increased number of experiments on the properties of the atom, and it was important that those experiments should be of as many different types as possible. The great majority of the experiments hitherto made had been on the spectroscopic properties of the atom; this was natural, for such experiments could be made with great accuracy, and the technique was well known. But, after all, the atom had other properties besides spectroscopic ones; from some points of view those other properties were of even greater importance, and he was not sure that the spectroscopic was the best method for distinguishing between different kinds of atoms. The same tunes could be played on many different instruments, and the tune was not always indicative of the instrument on which it was played. He looked forward to experiments on the magnetic properties of the atom, the deflection of the proton when moving through solids, the deflection of electrons of different speeds when moving through atoms of the inert gases, and to experiments on the chemical properties of gases when electrified. Much had yet to be learned about the electron and the proton, and he could not think that the physicist would always be content to think of just two little spherical masses, one positive and the other negative, as a sufficient explanation of the greatest of all physical mysteries. In concluding his lecture he put forward the view that the electrons and protons were not termini, but avenues leading to new regions as yet unexplored. The conception of the atom which he had in mind, as tentative as any other, was of a series of "thin" electrons arranged concentrically, separated by finite distances, the electrons being in equilibrium, not describing orbits, but statical, and occupying fixed positions. In fact, as he imagined it, the atom was more like a crystal, with a regular and orderly distribution of electrons around a centre, than like the planetary system, with which it was so often compared. One of the great advantages of the theory which supposed a statical or crystalline distribution of electrons within the atom was that it could be so much more easily visualized than could a system in which multitudes of electrons were supposed to be describing orbits in a kind of solar system—a thing which always made his own head whirl even as the electrons were whirling, and recalled the line, "For nothing's really anywhere, but always somewhere else."

THE CHAIRMAN OF COUNCIL.

SIR ROBERT BOLAM was elected by the Council of the British Medical Association as its Chairman, in succession to Dr. J. A. Macdonald, during the Annual Meeting at Cambridge in 1920. In 1923 at Portsmouth he was re-elected for a further term of three years. Last year at Nottingham he consented to serve again, but only for twelve months. On June 8th, during the last Council meeting held under his chairmanship in the house with which his name will always be associated, his colleagues joined in paying him a personal tribute. This took the form of a complimentary luncheon in the large committee

room and the presentation of a small gift. Sir Jenner Verrall, as the senior member of Council, took the chair. A formal account of so informal an occasion would be out of place, but it should not pass unrecorded. There were only two toasts—the Patron of the Association, His Majesty the King; and the Chairman of Council, Sir Robert Bolam, M.D., LL.D., F.R.C.P. Sir Jenner Verrall was in his happiest vein, and to those who know him that is saying enough. It was a short speech in which manner and matter were matched to perfection. He touched lightly on the peculiar virtues of the outgoing Chairman of Council, his genius for construction, and his great services to the Association. The confidence felt by the Council at Cambridge seven years ago had, he said, been more than justified. Sir Jenner Verrall ended by handing to the guest in the name of the hosts a gold-mounted Swan fountain pen, remarking that our ancestors, if they had tried to express their feelings in the same way, would no doubt have chosen a quill from a bird about to sing its last song. The toast, it need scarcely be said, was drunk with musical honours. Sir Robert Bolam, speaking as briefly in reply, thanked his colleagues for this compliment, and told them why he felt it right and wise to give up an office which had meant so much to him. His hobby, he said, had long been team-work, and his work on the Council had been happy because it was done by a band of brothers. He named two colleagues out of many who had helped him, because in a special way they had made easier the difficult early months of office—Sir Jenner Verrall and Dr. Macdonald. As for the officials to whom he owed so much, he believed that the secret of success in the work of the Association lay in a careful balance between the permanent staff and the voluntary officers. Having thus thanked and gently admonished his fellow councillors, the Chairman whom they had honoured in this friendly fashion called them back to their duties in the Council Chamber.

THE NATIONAL MUSEUM OF AUSTRALIAN ZOOLOGY.

In 1924 the Federal Parliament of Australia, knowing the fact that the unique native fauna of the Commonwealth was fast disappearing, and recognizing its importance to medical science, founded the National Museum of Australian Zoology. It was a wise and statesmanlike act, the full effect of which is only now beginning to be seen. Dr. Colin Mackenzie was appointed Director, with the title of professor of comparative anatomy. It was a museum with a difference. In the previous year Professor Mackenzie had presented to the Commonwealth his specimens of living native animals, together with the buildings and fencing on the Research Reservation at Healesville. He had given also his collection of macroscopic and microscopic specimens, numbering many thousands; and these now form the basis of the museum collection. Each specimen has a direct application to some medical or surgical problem. Nothing quite like the collection of normal histological preparations from reptiles, monotremes, and marsupials, with which human or other mammalian tissue can be compared, exists anywhere in the world, and we are glad to know that illustrated atlases describing the collection are being prepared for publication—a huge enterprise which has been begun not a day too soon. Early in 1923, when commenting on the announcement that the Commonwealth Government had passed an Act to establish a Museum of Australian Zoology, we observed that there was clearly an obligation on Australia to preserve a full series of specimens, since the whole indigenous fauna of Australia seemed only too likely to follow Tasmanian man to extinction. The Commonwealth Legislature has now gone rather further than we hoped, for it has not only allotted a site for the National Museum of Australian Zoology at Canberra, the new capital of Australia, but the Federal Capital Commission has provided a site for a zoological park or reservation, in which will be kept living specimens of Australian and Tasmanian native animals in their natural state. The area of the site for the museum, laboratories, and lecture theatre is about five and a half acres, in a magnificent situation on Acton Hill, facing Parliament House. The research reservation or zoological park, containing about eighty acres, is on a peninsula bounded on two sides by the river Molonglo. The report of the Parliamentary Standing Committee on Public Works, dealing with the construction of buildings, has now been published, authorizing for this purpose a sum approximating £100,000. The report has received the unanimous approval of the Federal Parliament, and the buildings, representing what is really the first stage in the establishment of the National University of Australia, will be begun immediately. When the buildings are completed every facility will be offered to workers—not only Australian, but also from other countries—wishing to study comparative anatomy and its application to modern medical and surgical practice. The museum is now at Melbourne, but is to be moved to Canberra next year. To its original contents many important additions have recently been made, including the collection of specimens valued at £25,000 belonging to Dr. George Horne of Melbourne, dealing with the Stone Age men of Australia, and also a collection of aboriginal skulls made by Dr. Arthur Nankivell of Kerang. The museum also possesses the Froggatt entomological collection, and that of Mr. Murray Black dealing with the aborigines of South-East Victoria. The completely fossilized prehistoric Cohuna skull, together with many other specimens of anthropological value, belong to the museum. The Federal Government of Australia is to be congratulated on its decision to establish a centre for the advancement of comparative anatomy, which admittedly is the foundation of all the medical sciences. We may venture to express the hope that the lead now given by Professor Colin Mackenzie will encourage wealthy Australians to display a similar national spirit, and by liberal endowments help on the necessary research work in the interests of humanity.

THE SURGICAL ASPECTS OF ACROMEGALY.

THE Annual Oration of the Medical Society of London was delivered on June 13th before a crowded audience by Professor Harvey Cushing, Hon. F.R.C.S., whose subject was "The surgical aspects of acromegaly." Sir Humphry Rolleston, who presided, introduced Professor Cushing as the leading neurological surgeon of America, one who might well be described as a physician able to use his hands, and whose hands could not only wield the knife, but that more powerful implement the pen; Professor Cushing was the author of a charming biography of a former Orator, Sir William Osler. The text of the Oration, with numerous illustrations, will be published in an early issue. Sir Charles Ballance, before proposing a vote of thanks to the Orator, said with what pleasure the Fellows of the society saw among them that evening Sir David Ferrier, the doyen of neurologists in this country. In Professor Harvey Cushing they had a man who had done more than anyone living for neurological surgery. He remembered Cushing when, a shy, retiring young man, he visited London about 1892, his purpose being to observe the work done at University College, and at the National Hospital in Queen Square. Ten or twelve years later, at the Johns Hopkins Hospital, he found the same shy and retiring man at the head of a most magnificent neurological department, a department which Cushing himself had created. Searching recently in the library of the Royal Society of Medicine, he discovered about 180 published books, papers, and addresses under the name of Professor Cushing. No words

of his could ever sufficiently praise one whom he felt to be a Paladin of surgery. Sir StClair Thomson seconded the vote of thanks, remarking that his own specialty, oto-laryngology, had contributed something to the elucidation of the problem under discussion, and a distinguished laryngologist from abroad who was present, Professor Sugara of Buenos Aires, had performed no fewer than forty operations on the pituitary gland. Sir Humphry Rolleston put the vote of thanks, which was carried by acclamation. Professor Cushing said that he did not deserve the encomiums; he feared that some of the achievements with which he had been credited, including some of those 180 publications, had been wrongly ascribed to him, for there were other Cushings in the States, with whom he was occasionally confused.

THE WATCH ON THE RIVER.

OF sundry advantages which have accrued to this country through the growth of a sanitary conscience there is probably none which has been more conducive to the general health and well-being than the copious provision of wholesome water now available in every great city, and, with few exceptions, in every considerable centre of population throughout the breadth of the land. Whether drawn from recesses of the earth, or distant hills or adjacent rivers, these supplies are conveyed abundantly by various channels into the houses of consumers, who by force of habit have come to regard them very much as a matter of course, or as natural benefits free to all, like sunshine and fresh air. While this disposition to take it for granted may perhaps have some excuse in the case of deep protected wells or waters flowing from untrodden uplands far from the haunts of men, it is quite otherwise with undertakings which abstract their raw water from the polluted rivers that traverse a peopled country. Consumers of supplies like these, which are made and kept wholesome chiefly by means of the untiring vigilance of the officials in charge, may, when forgetful of these their blessings, quickly recapture a proper sense of what they owe to the supervisors of their drinking water by a perusal of such reports as that of Sir Alexander Houston, Director of Water Examination to the Metropolitan Water Board, summarized on page 1122 of this issue. The report conveys to the mind an impression of unrelaxing care enlightened by a comparative study of similar work in other situations. In this report, and throughout the series of his reports from 1906 onwards, including those on research, the director appears to have constantly had before him the quality of the raw waters entering the London works, as contrasted with the same waters after storage but prior to filtration. Up to 1922-23 it had been his practice to make bacteriological examinations of selected samples of the pre-filtration waters; in that year he extended his scrutiny to all pre-filtration waters, holding the view that, if he could establish that the pre-filtration waters, as a class, were safe, the whole fabric of Thames purification would rest on so broad a basis that occasional caprice on the part of individual filters would cease to be of primary importance. The comparison for 1926 as regards *B. coli* between the raw Thames and the stored waters, including the chlorinated waters, shows that, whereas 35 per cent. of samples of the raw Thames water contained *B. coli* in 0.1 c.cm. or less, the usual effect of storage was to improve the water at least a hundredfold. The principle is one which applies not to water purification only, but to most mundane enterprises. The lighter the task of the last line of defence the greater the degree of security. The immunity of London from disease accredited to its water is a vindication of this policy, and a happy result of the watch on the river maintained by Sir Alexander Houston. The public may be reminded that this happy condition of British water supplies has been brought about in consequence of the efforts made during the last quarter of the nineteenth century by the medical profession, who in various ways—by clinical observation, by epidemiological studies, and by bacteriological investigation—succeeded in proving that many diseases, and chief among them epidemics of typhoid fever, were due to contaminated water.

PROPOSED EXTENSIONS OF INSURANCE BENEFIT.

IT is understood that either in the autumn session this year, or early next year, the Government will introduce into Parliament a bill proposing some amendments of the National Health Insurance system, including some extension of the scope of medical benefit. The bill is certain to be of a much more modest character than was until lately hoped for. The present attitude of the approved societies makes it impossible to carry out even the most beneficial and least alarming recommendations of the Royal Commission with regard to such extensions. The societies are, it seems, looking forward with some apprehension to the results of their third valuation, and so are refusing to consider any such pooling of surpluses as would be required by the proposals of the Royal Commission. They are naturally cautious in their outlook, and have a laudable desire to command immense reserves. It is, of course, possible, especially in view of the gratifying results of the last two valuations, so largely beyond expectations in each case, that their apprehensions may prove unfounded; but unfavourable industrial conditions are no doubt having an adverse effect, and it may well be that the results of the third valuation a few years hence will be less abundantly satisfactory than those of the other two. It is interesting, therefore, to gather from reports of recent meetings of approved societies—as, for instance, the Whitsuntide conference of the Manchester Unity of Oddfellows at Great Yarmouth—some idea of the nature of the proposals which they intend to allow the Ministry of Health and the Government to make. The establishment of a full consultant and specialist service, or even of a laboratory service, is not to be permitted; but it is suggested that "some of the more essential treatment benefits"—presumably those known as dental benefit and ophthalmic benefit—may pass from the category of "additional benefits" and become part of the statutory "medical benefit," or be placed upon a footing analogous thereto. This would mean that they would be available for all insured persons instead of for some, and that they would be provided and administered by Insurance Committees instead of being under the auspices of the approved societies themselves, or of such organizations as the National Insurance Benefit Society, which are almost indistinguishable therefrom. These would be important alterations in a right direction, but will require the close attention of the profession, and especially of the Insurance Acts Committee and Ophthalmic Committee of the British Medical Association. Further, it is suggested that another anomaly of the approved society system may be modified. Each branch of a friendly society is at present an independent entity for valuation purposes, so that we may find that within a single society in the same town there may be one branch or lodge which provides for its members one kind of additional benefit, a second lodge which provides another kind, and a third lodge which finds itself unable to provide any additional benefit at all. The Manchester Unity, at any rate, has now got so far as to sanction the seeking of power to permit of "the creation within the society of a central fund by the allocation thereto of one-third of the disposable surpluses of all lodges, this fund to be distributed so as to enable lodges to provide such a minimum of certain treatment benefits as may be decided upon." Thus is it possible to contemplate a small but

welcome advance from a state of things which many observers have long regarded as an absurdity. It will be interesting to note the movements of the Ministry of Health within the relatively small field to which the cautious finance and commanding position of the approved societies is confining them.

MENTAL DEFICIENCY ADMINISTRATION.

WE publish this week a letter from Dr. Tredgold, in which he discusses the leading article on mental deficiency administration published in our issue of June 4th (p. 1020). There are two chief points raised by Dr. Tredgold requiring, as he thinks, modification of the policy of the British Medical Association, the main principle of which—unification of the administration of health services both centrally and locally—he accepts. These two points are: (1) that instead of there being one chief *administrative* officer there should be two, one the medical officer of health, as now, and one, of independent and equal authority, a medical officer of mental health; (2) that the subordinate medical officer dealing mainly with mental deficiency work should be in personal contact with, and directly responsible to, the statutory committee concerned. Both these suggestions may well be made the subject of debate, but in view of Dr. Tredgold's own statement that "disease of mind should be regarded as part of disease in general," and having regard to the intimate connexion of mental deficiency in children with the other aspects of school medical work, and of mental deficiency in adults with the same condition in children, the former suggestion does not seem to have much validity; and its adoption would be a radical departure from the policy of the Association. In so far as the medical officer of health is not himself expert in the subject of mental deficiency he would, as Dr. Tredgold says, delegate such work to "an assistant possessing the necessary qualifications," exactly as he frequently does in the other special spheres of clinical work. The second suggestion, that such subordinate officer should be in direct relationship with the appropriate committee, is not necessarily in conflict with the Association's policy, though it is contrary to the usual custom of local authorities, who require the attendance at their meetings of their principal officer only. It is quite possible that in some cases where the main part of the work is undertaken by an assistant medical officer, it may be desirable that he should attend with his chief at the meetings of the committee.

THERAPEUTIC SUBSTANCES ACT.

IN an article on the Therapeutic Substances Act, 1925, published in the BRITISH MEDICAL JOURNAL of April 16th last (p. 737), we gave an account of the draft Regulations issued by the Joint Committee regarding the manufacture and importation of therapeutic substances scheduled in the Act. The Regulations, as finally revised, will come into operation on August 6th next, except those relating to labelling, which will come into operation on February 6th, 1928. Persons desiring to manufacture or import any scheduled substance after August 6th in Great Britain or Northern Ireland will require a licence. Applications should be made immediately, addressed in the case of England and Wales to the Ministry of Health, Whitehall, S.W.; in the case of Scotland to the Scottish Board of Health, Edinburgh; and in the case of Northern Ireland to the Ministry of Home Affairs, Belfast. The Regulations now issued differ in some respects from the draft published on April 5th, certain modifications having been made to meet representations received. Copies of the Regulations are obtainable from H.M. Stationery Office at Adastral House, Kingsway, London; 120, George Street, Edinburgh; York Street, Manchester; 1, St. Andrew's Crescent, Cardiff; 15, Donegall Square West, Belfast; or through any bookseller. The Minister of Health has intimated to the Association of British Chemical Manufacturers that in the initial period immediately after August 6th some latitude will be observed in the application of the Regulations, so as to allow for the clearance of existing stocks and for those concerned to become familiar with the new requirements.

INTERNATIONAL CONGRESS OF OTO-RHINO-LARYNGOLOGY.

IN the days before the war there used to be held at intervals an International Congress of Laryngology. The last pre-war meeting was held in Berlin. Since the war this congress has not been revived, although there was a very successful Congress of Otology in Paris, under the presidency of Professor Sebileau, in 1922. We are now glad to hear that the supporters of both these congresses have combined in launching an International Congress of Oto-Rhino-Laryngology. It will be the first of its kind, and will be held in July, 1928. It should be successful, for many reasons: it will be held on the neutral soil of Denmark; Professor Schmiegelow, the doyen of the specialty in Scandinavia, is the president, and he will be supported by a strong committee, who are all well known workers and very welcome visitors to this country. Finally, Copenhagen at the end of July will be looking its best, and should form a most delightful meeting ground.

OLD MEDICAL BOOKS.

AN unusual type of legacy to a voluntary hospital, and one which may possibly set an example for other testators, is that of the late Mr. W. Ward-Cook in bequeathing to St. George's Hospital a small library of choice books, to be sold for the benefit of the charity. The sale takes place on June 22nd at Messrs. Sotheby's; there is no item of great rarity, but it is to be hoped that a fair average price will be obtained for the score or so of lots into which the collection is catalogued. At another sale room—Messrs. Hodgson's in Chancery Lane—a pamphlet entitled "The Last Will of Thomas Guy, Bookseller" (1725), is to be sold on June 17th. This, presumably, is the will by which Guy's Hospital was founded, unless it is a contemporary skit or lampoon based on the curious and well known incident of Guy's revocation of his previous will, by which he had left his valuable estate to his cook. The same sale includes several other medical books and pamphlets. There are a number dealing with the early days both of inoculation and of vaccination for small-pox; these include an "Account of the Effects of Swinging as a Remedy in Consumption" (1787), "Richard Guy on curing Cancer without Cutting" (1764), Rowley's book on "Diseases of the Breasts of Women" (1772), Willis's "Preservative from the Infection of the Plague" (1721), Pitcarne's "*Treatise on the Stone*" (1739), *Fothergill* on "Sore Throat" (1748), Pugh's "Midwifery" (1754), and many others.

SIR BERKELEY MOYNIHAN, Bt., President of the Royal College of Surgeons of England, has accepted an invitation to take charge of the work of the Surgical Professorial Unit at St. Bartholomew's Hospital and Medical College from June 15th to June 30th. It will be remembered that on previous occasions Professor Harvey Cushing of Harvard University, U.S.A., and Professor Hugh Cabot of Ann Arbor University, U.S.A., accepted similar invitations at St. Bartholomew's Hospital.

BIRTHS AND DEATHS REGISTRATION ACT, 1926:

WITH SPECIAL REFERENCE TO DEATH CERTIFICATES.

THE Births and Deaths Registration Act, 1926, will come into force on July 1st next. It will be remembered that this Act, for which Dr. F. E. Fremantle, M.P., was largely responsible, deals with the registration of stillbirths, the certification of deaths, and the disposal of bodies. The discussions in Parliament, from the introduction of the bill until it became an Act in December last, have been reported in the JOURNAL in considerable detail, and comments have from time to time been made; but it is essential that the alterations in the law which, in their final form, will now become operative should be fully understood by every registered medical practitioner, not only that he may himself conform to them, but that he may be able to advise his patients how they should act in certain circumstances in which they will naturally look to him for help.

Disposal of Bodies.

With regard to the disposal of the body of a deceased person the Act now prohibits such disposal except on a registrar's certificate or coroner's order; but in order to meet the case where a burial (but not a cremation) is actually in progress and the certificate or order is for some reason (for example, forgetfulness or carelessness) not produced, there is a proviso that the person effecting the burial may nevertheless proceed if satisfied by a written declaration in prescribed form by the person procuring the burial that such certificate or order has in fact been issued. It is further provided that no body may be removed out of England without notice being given to the coroner within whose jurisdiction the body is lying, and the Ministry of Health is empowered to prescribe the period and form of such notice and the procedure upon removal. The Ministry of Health may also make regulations "imposing any conditions and restrictions with respect to means of disposal otherwise than by burial or cremation, as to the period of time a body may be retained after death in an inhabited house or other premises, or with respect to embalming or preservation." It will be advisable for practitioners to familiarize themselves with such regulations when they are issued.

Stillbirths.

With regard to stillbirths, these will now have to be registered in much the same way as though the child had been born alive. The person whose duty it is to give information to the registrar is the person who would have had to give information if the birth had been a live one, and such person is required either to "deliver to the registrar a written certificate that the child was not born alive signed by a registered medical practitioner or certified midwife who was in attendance at the birth or who has examined the body of such child" or to "make a declaration to the effect that no registered medical practitioner or certified midwife was present at the birth or has examined the body, or that his or her certificate cannot be obtained, and that the child was not born alive." The burial of a stillborn child by "a person who has control over or who ordinarily buries bodies in any burial ground" is prohibited "in such burial ground" without a registrar's certificate, or, if there has been an inquest, a coroner's order. A stillborn child is defined as one "which has issued forth from its mother after the twenty-eighth week of pregnancy, and which did not at any time after being completely expelled from its mother breathe or show any other signs of life." It seems clear, therefore, that, though the law with regard to stillbirths has been improved and strengthened, there are still undesirable loopholes of which advantage might possibly be taken. A child whose head or whose head and trunk had been born and who was breathing normally might be caused to cease to breathe before the legs had issued from the vagina, and this would, in law, be a stillbirth. If there has been no doctor or midwife in attendance and the birth registered there need be nothing more than a declaration by informant that the child was stillborn. This would enable the body to be buried "in a burial ground"; and there are no provisions with respect to the private disposal of such a body elsewhere. Attention was drawn to the question of the legal definition of live birth by a valuable paper by Dr. Godfrey Carter, read at the Section of Public Health at the Annual Meeting of the British Medical Association at Nottingham last year, and reported in the JOURNAL of August 28th, 1926 (p. 385). The Section passed a resolution on the matter which is still under consideration by the Medico-Political Committee of the Association; that committee may find that the position has been made even more difficult by the definition of stillbirth in the Act of 1926. It should be noted that no official form for a medical certificate of stillbirth is being issued, but every such certificate should include the statement that the practitioner was in attendance at the birth or had examined the body, and should give the names and surnames of the parents (or mother) and the date of the birth.

Death Certificates.

With regard to death certification, the Act makes several important changes in the law, and these, together with the action now taken by the Registrar-General in accordance therewith, will entail certain alterations in methods or practice in this connexion to which medical practitioners have been long accustomed. It is essential that these changes should be appreciated, and that, as from July 1st next, the new requirements should be strictly observed. Since the year 1874, in case of the death of any person who has been attended during his last illness by a registered medical practitioner, such practitioner has been required to give a certificate stating to the best of his knowledge and belief the cause of death. Such certificate must, from the time the new Act comes into force, be given in the prescribed form and in no other. The prescribed form is that contained in the books of forms supplied to practitioners by the Registrar-General through registrars of births and deaths; and no medical certificate of cause of death may be given on this form unless the certifying practitioner has been in attendance upon the deceased during his or her last illness. Changes are made (1) as to the manner in which the certificate, when completed, is to be dealt with; and (2) as to the manner in which the particulars of the cause of death are to be stated.

Hitherto the certifying medical practitioner has been accustomed to hand the certificate to a person liable to act as informant of the death for registration purposes. Henceforth it will be his duty to give to such person only a written notice that he has signed the certificate, and to send the certificate itself direct to the registrar. To facilitate the performance of these duties, (1) the form contains a tear-off portion, bearing the same serial number as that borne by the certificate itself, which must be used by the practitioner in giving the required notice to the relative or other proper person; (2) the registrar will supply the practitioner with official franked envelopes in which the certificates are to be posted to the registrar. These envelopes are not to be used for any other purpose, and no alteration may, in any circumstances, be made in the printing on them. Thus the new form of certificate is in triplicate: (1) a counterfoil for the use of the practitioner, who should in all cases fill it up; (2) the actual certificate of cause of death; (3) the notice to the informant that the certificate has been signed.

The New Certificate: Causes of Death.

The most important alterations in the form of actual certificate are as to the manner in which the particulars of the cause of death are now to be stated. In a very large number of cases only one cause of death needs to be given, but where there are two or more causes these have been placed, in the form of certificate hitherto in general use, under the headings "primary" and "secondary." This has been found to give rise to confusion and to vitiate the mortality statistics, which must necessarily be based upon certificates of death. In the new certificate form this distinction and nomenclature is abandoned, but it is still divided into two sections. In the former section the practitioner is required to enter the immediate cause of death and any morbid conditions which led up to it, these

being stated in order backwards from immediate to remoter causes. In the latter section should be entered "conditions which are not in the chain of pathological events which have led to the immediate cause of death, but which have none the less contributed seriously to the fatal issue." This is a much more clear and logical arrangement than the old; and an appeal is made to the medical profession for co-operation in securing statements in this way which will be reliable, which will be as accurate as possible, and which will thus materially assist the compilation of true mortality statistics, the importance of which for many public purposes is fully recognized. By being careful and accurate in stating the required particulars medical practitioners will, in fact, be contributing to valuable research work in which both they and the public are vitally interested. Members of the profession in general practice have often, through their representatives, expressed their wish to undertake appropriate research work, and it is to be hoped and expected that full advantage will be taken of this new opportunity. The seven examples of the method of using the form given in each book of forms should facilitate a clear understanding of what is required, and the list of indefinite or undesirable terms which are to be avoided will contribute to uniformity of nomenclature and accuracy of statement. Particular attention is directed to the requests that in cases of cancer the seat of primary occurrence should be stated whenever this is known, that whenever pregnancy or parturition has been a contributory cause of death this should be mentioned, that when death is attributable in any degree to anaesthetics the nature of the anaesthetic should be recorded, and that in deaths from violence, whether accidental, suicidal, or homicidal, it is desirable to state not merely the nature of the injury but also the form of violence and the means of violence (for example, "run over by a motor-car").

As part of the certificate the practitioner is required to state whether he last saw the patient alive, whether or no he viewed the body after death, and whether or no a necropsy was held. On the back of the form are two statements, one or other of which should initialled under appropriate circumstances. One of these statements is to the effect that the certifying practitioner may be in a position later to give more precise additional information as to the cause of death, as a result, for instance, of some laboratory or *post-mortem* examination. In the event of this statement being initialled, the Registrar-General will in due course apply to the practitioner for any further information which he may then be able and willing to give. The other statement is that the certifying practitioner has reported the case to the coroner. It will be observed that the reporting of a case to the coroner does not justify the omission to give a certificate of the cause of death. As the law now stands, and as it will continue to stand, the duty placed upon a registered medical practitioner who was in attendance upon a deceased person in his or her last illness to give a medical certificate of the cause of death to the best of his knowledge and belief, is unaffected by the fact that he or some one else has reported the case to the coroner or that an inquest is to be held. The practice of refraining from giving a death certificate in these circumstances has, however, been not uncommon, and has been based upon the fear that, if a medical certificate were given, the death might forthwith be registered, and the body disposed of before an inquest could take place. The statement on the back of the new form of certificate should obviate any such risk. Where this statement is initialled by the practitioner it will be the duty of the registrar to suspend the registration of the death until he learns from the coroner whether an inquest is or is not to be held.

Viewing the Body.

In the course of the passage of the bill through the House of Commons a strong attempt was made to enforce upon a certifying practitioner the duty of viewing the body after death in every case, or at the very least to secure such inspection in a far larger proportion of deaths than at present. As this was a private member's bill, however, it could not contain any proposal for imposing or increasing any charge upon public funds; and it was further pointed out that the difficulty in this matter was not one merely of expense, but of its impracticability, especially in rural areas, owing to the call upon the doctors' time, and that in a considerable number of cases this *post-mortem* inspection was not really necessary. Sir Kingsley Wood, Parliamentary Secretary to the Ministry of Health, in a speech which was reported in the JOURNAL of December 4th, 1926 (p. 1084), said that it was proposed to extend the system of reference by registrars to coroners, which at present operates in cases where there is no medical certificate or where the death is due to an accident, an industrial disease, or other cause appropriate for consideration, to certain other cases arising out of facts disclosed by the medical certificate of the cause of death. "The certificate would show whether the doctor had seen the deceased after death, and how long before death he last saw him alive; and it would thus be possible that any case not seen after death or a reasonably short period before death would come under review by the coroner before registration or burial. It was to be anticipated that this arrangement, besides bringing a large class of the more doubtful cases under special review, would greatly increase the proportion of cases seen by a doctor after death, and the improvement in that respect would be progressive." It is understood that registrars have been instructed that when they receive a death certificate in respect of a person who has not been seen by a doctor subsequent to death nor within fourteen days before death they are to refer the facts to a coroner. The Council of the British Medical Association, who were consulted by the Registrar-General in this matter, have raised no objection to the period of fourteen days referred to, but they drew attention to the certification rule under national health insurance which allows an insurance practitioner in certain circumstances to issue monthly certificates of incapacity to insured persons who are suffering from chronic illnesses. In this connexion it is desirable, since the extent to which the bodies of deceased persons are seen after death by a medical practitioner is a matter of some public interest, and since arrangements have been made for the publication of annual statistics with reference thereto, that the medical officer of an institution, in giving a death certificate in respect of an inmate whose body has not been seen after death by him, but has been seen by some other medical officer, should mention this fact. A slight alteration of the words on the prescribed form of certificate will enable this to be done, and such alteration is sanctioned by the Registrar-General.

ROYAL MEDICAL BENEVOLENT FUND.

At the last meeting of the Committee thirty-six cases were considered and £690 voted to thirty-four applicants. The following is a summary of some of the cases relieved.

L.R.C.P., aged 82, a widower with one daughter. He had to give up practice on account of age and deafness; his savings, with those of his daughter, were invested in purchasing the house they now live in. Three rooms are let for 25s. a week. He has the old age pension and his daughter receives £20 as an organist. Interest on mortgage £24 per annum; ground rent £7; rates £20. Voted £40 in twelve monthly instalments.

Daughter, aged 79, of M.R.C.S. who died in 1885. She suffers from rheumatism and double cataract. She has two pensions, one of which is the old age pension; these amount to £66 per annum. £5 is received from investments, and £65 from letting. Applicant's sister, who was an annuitant of the Fund, died last month. Voted £20 in twelve monthly instalments.

Widow, aged 65, of F.R.C.S. who died in 1912. At present is ill and asks for expenses to go to a convalescent home. Total income £60 per annum. Voted £5.

Widow, aged 70, of L.R.C.P. who died last month; he was an annuitant of the Fund. Applicant only has the old age pension. Voted £26 in twelve monthly instalments.

Son, aged 16, of M.B.Glas. who died in 1924. Mother is in a mental hospital. The boy is in charge of an uncle, who is not able to keep him entirely. He earns 10s. a week as an engineer's apprentice. Fund repeated the grant of £26 towards his maintenance.

Son, aged 3, of L.R.C.P. who died in 1926. This boy, with his two elder brothers and one sister, are entirely dependent on an uncle, who is unable to meet all the expenses of maintenance and education. Voted £25 towards maintenance.

Subscriptions may be sent to the Honorary Treasurer, Sir Charters Symonds, at 11, Chandos Street, Cavendish Square, London, W.1.

The Royal Medical Benevolent Fund Guild still receives many applications for clothing, especially for coats and skirts for ladies and girls holding secretarial posts, and suits for working boys. The Guild appeals for second-hand clothes and household articles. The gifts should be sent to the Secretary of the Guild, 58, Great Marlborough Street, W.1.

THE FAMILY DOCTOR AS SPECIALIST.

ABSTRACT OF THE ALEXANDER BLACK MEMORIAL LECTURE.*

BY

C. E. DOUGLAS, M.D., F.R.C.S.ED.,

AFTER a short tribute to the memory of Miss Ann Black, the foundress of the lectureship, and of her brother, the subject of the address, the lecturer went on to say that he desired to indicate some lines of activity in his own sphere, and not to trench upon the specialized work outside it, in which the family doctor might yet be of great service to the community. It was for the family doctor first to keep alive the great truth of the inherent unity of medicine in all its forms. Secondly, in his work there were positions occupied by him which by their very nature could not be occupied by anyone else, and in which much useful work might be done. Thirdly, the lecturer wished to consider the ethics of the family physician: what in him was the result of the impact on his mind of the vast body of "disharmony" with which from first to last he had to contend.

The Family Doctor in History.

To those with the historic sense the history of medicine conjured up a long vista into the past. Through Babylon and Egypt we came to Greece, the motherland of Medicine; she was truly our spiritual home; it was from her that we drew our earliest nourishment, in common with Art, with Music, with Literature, and Philosophy. We thought of Hippocrates, the Father of Medicine, and still looked to him as our teacher in the higher ethics of the profession. The high ideals of those times were still around us; the Sarastro chain of the high mission to humanity, the Democedes chain of loyalty to co-workers, and the Hippocratic chain of devotion to our suffering clients and to "the Art." The beautiful shadow of Apollo hovered over us still, Harvey himself was full of his debt to Aristotle and the ancients, and it should be noted that all these makers of medicine, from Democedes to Harvey, were men in the general practice of medicine, and the line went on through Jenner, another epoch maker, down to our own Mackenzie. The family doctor was the lineal descendant of these makers of medicine; he stood in the forefront of the battle against disease, and it was his *métier* to represent the inherent unity of his art in the world of medicine, and to act as its general interpreter to his patient.

The Family Doctor as Specialist.

A century ago medicine in this country was in a rather inchoate condition. There was no true corpus of medicine, but the family doctor had become of some importance socially. Instances of the light in which he was regarded were quoted from George Eliot and Oliver Wendell Holmes, and the life and work of Dr. Francis Adam of Banchory—who combined general practice and a profound knowledge of the Greek classics and of nature—was described. About that time there arose Charles Hastings, an Englishman, who went out from Edinburgh University carrying with him its fine atmosphere of culture, of plain living and high thinking, and *camaraderie* between lawyers, doctors, ministers, and all cultivated beings. He conceived the idea of a society of medical men that should make for the "honour and respectability of the profession," and the result of his labours we know to-day as the British Medical Association—the outward and visible sign that doctors were a band of men united in aim and living to some extent in unity with each other. A second factor was the passage of the Medical Act in 1858, in which by the creation of the General Medical Council a certain high standard has been set and maintained. The medical man of half a century ago was probably at as high a point in the society of his day as he had ever been. From this time onward, however, there arose three factors which had tended towards a decline in the usefulness, and therefore of the status, of the family doctor. The first was the rise of the antiseptic system of surgery; this affected him in two ways: by widening the possibilities of surgery so that he could not hope to keep pace with it; and by attracting into surgical practice many of the keener men, who might otherwise now be in general practice. The second factor was the tendency towards collectivism in dealing with matters of public importance, such as the prevention of disease. The other and most deteriorating factor was the National Health Insurance Act. This was said by the lecturer in quite a definite and restricted sense. From the point of view of the community the system was as nearly an unmixed blessing as might be; its influence upon that part of the profession which carried out its provisions was not so good, and was one that might tend towards deterioration. Public moneys were involved; and on the plea that these must be safeguarded the medical profession was saddled with the responsibility of carrying this out by a system of regulation entirely foreign to it, and tending to check any advance in efficiency in its own proper sphere. A cumbersome form of certificate, with regulations to enforce it, was the bugbear on the one hand, and on the other, a "checking bureau," which was on the alert to insist upon economy in prescribing; these two, with the resulting complaints, exactions, fines, and humiliating appearances before Panel Committees, could not fail to have a demoralizing effect upon the panel doctor, who was the family doctor of the working classes, and to degrade him in the eyes of the general public. Materially he is better off, but from any but the financial aspect he is in a miserable plight, tied up by red tape in all directions, and wasting in certification, prescription checking, and recording every trifling scratch and passing ailment, time which should be devoted to the practice of medicine. These three factors had brought it about that the men now in general practice had not the standing of their predecessors of fifty years ago, and the process of deterioration was likely to become more marked as the years went on.

There was, however, a way back to a considerable and respectable place in the medical world: the family doctor was better placed for the observation of certain things than any specialist. To this three objections might be brought: first, the duty of a family doctor was to make use of the results of research, not to carry it out in its scientific aspect; secondly, a family doctor who became particularly interested in any branch of medicine was apt to make it his whole work, and to become a specialist; and lastly, and most important, the limited experience of any one man. In spite of these objections there were directions, untouched by others, in which he might do good work.

First, the study of the beginnings of disease. This was the burden of Sir James Mackenzie's mission; for thirty years he worked to show that in the study of the beginnings of disease there was a virgin field, and that the family doctor was the only one who could work it. In the scientific world Mackenzie was probably remembered as the inventor of the polygraph; but it could not be too strongly insisted upon that his claim to lasting fame rested upon the discovery of an idea, and not of an instrument. This idea was now being carried out at the James Mackenzie Institute at St. Andrews, where the different signs and symptoms of disease were being considered, and the observations tabulated, so that in time a body of evidence might be collated which would throw light upon the beginning of disease; and this work was being done by men in general practice.

Secondly, the practice of what might be called "urgent surgery." The man in country practice, far from the great centres, could save much suffering to the patient, and loss of time in removing an acutely ill case to a distant hospital, if he were able and willing to do such operations as those for strangulated hernia, suture of a ruptured gastric ulcer, appendicectomy, and tracheotomy. The country doctor, then, should specialize in this urgent

* Delivered before the Royal College of Surgeons of Edinburgh, June 15th, 1927.

surgery, not in the sense of special research, but in that of keeping himself fit to deal with urgent cases as they arose.

Thirdly, collective investigation, by men in general practice, of diseases which did not present themselves to the specialist.

Fourthly, a special line—prevention. The family doctor should have opportunity of observing the family in health, on the analogy, now so usual, of taking children to the dentist at regular intervals.

Fifthly, he might exercise the "scientific imagination." This was a contradiction in terms, synonymous with the deductive method. It had already been suggested that the inductive method, involving as it did prolonged research, was practically out of reach for the man in general practice, who seldom saw enough of any one kind of case to form a sound induction. But there was the other method, that of deduction, of synthesis; and it was this habit of speculative thought that had been used by most of the men who in general practice had contributed to the advance of medicine—Harvey, Jenner, Lister, James Mackenzie, men all of the deductive cast of mind. Some examples from recent medicine were the use of salicin in rheumatism, by the late Dr. T. J. Maclaren of Dundee; of thyroid in skin diseases, by Sir Byrom Bramwell; and the speaker's theory of the increased susceptibility of the pregnant woman to disease. Akin to this deductive faculty was that valuable asset to any man in general practice—a sound clinical instinct.

Work such as this was well worth the attention of the members of our body who wished to maintain the standards of their forebears. The times had changed, and we had changed with the times. It was almost a truism to say that new laws tended to produce results never dreamed of by their makers. This applied to the National Health Insurance Acts. No one thought of them as tending to change fundamentally the main activities of the medical profession. And yet they were, in the ways already indicated. The doctor's time was so much taken up with records of trivial events, with writing certificates, writing and re-writing prescription forms (largely, if not entirely, for the convenience of the approved society officials, and for prevention of fraud by chemists), that a very substantial part of his time, which should be given to nothing but the practice of medicine, was wasted, and he was becoming merely an official concerned in administration of funds—work which could be done by lay people, and done quite as well. It was work foreign to him; he was not, as a rule, a good business man, and he often did it carelessly, with the result of "breach of regulations," censure, perhaps fine, and in any case a lowering of his prestige as a member of a profession whose proper work was on a higher plane, and which he probably did as well as anyone. Might it be found possible some day to hark back to the fundamental truth that the doctor's work was the treatment of disease and nothing else?

The Ethics of Medicine.

The family doctor had yet another use to the community; he stood in a very special position in regard to his patients, a position quite separate from the professional one. His work brought him into very close relationship in many a home. In many aspects of life all sorts of things were brought to the doctor for advice, giving him probably as full an idea of the lives of the people, their wants and difficulties, as most. Again, doctors lived in a strange environment of disease and pain and weakness, among "disharmonies" of every physical and psychic kind. Their work was largely with the unfits and misfits of life, seeking to refit them more or less for the work they had to perform. The great mass of healthy folk, who never needed their aid, lay outside their purview.

Thus doctors lived in an artificial world of disharmonies. What was the effect upon their mind? On many it had none. Most men did not dwell on the sad, tragic, or revolting aspects of medical life; but many thought it over and tried to evolve some explanation of this perennial struggle of mankind against its environment of disease and suffering. As usual it was well to go back to Greece to find the first questionings and the noble responses. Just as there were two classes of thinkers always with us—Platonists and Aristotelians, Idealists and Realists—so in this quest we found those who hold that happiness was the prime object of man—the Epicureans; and what might be called the nobler sort, who held that to look for happiness merely was to pursue a chimera which would never be found, or, if found, would only disappear—the Stoics. One or other of these must be chosen, and in these days the Epicurean would gain a clear majority vote. The atmosphere to-day was one of conscious seeking of pleasure, anywhere and everywhere. Was it worth while suggesting that this was a passing phase, recurrent at certain periods of our history? For the spirit of man was built for nobler things. There was that in the Stoic philosophy which found its counterpart among the finer races of mankind at all times and places, the instinct, namely, that the pursuit of self alone brought no real and lasting satisfaction; that something else was wanted—the other than self. There was in man the sure knowledge that suffering was not all to the bad, that to endure was to become strong, that the plaint of Faust, "entbehren sollst Du, sollst entbehren," had some justification if the race was to maintain its high traditions. The great ones of the earth were not reared in the lovely isles of the sea, or the tropical belt, but in the rugged hill countries where Nature was harsh, and brought up her sons inured to cold and hunger and fatigue. Look again at the sick beds one knows, of patients often racked with pain. How patient, how thoughtful of others, how resigned to suffering were these; if the spirit of man were not in them being "made perfect through suffering," then there was no meaning in it. There was in man something more than the quest of happiness. That quest found its fruition easily, and its end was not peace, but mere satiety. The other, the not-self, was it not that for which the medical art existed? Were not its votaries of all grades and branches guided by the same instinct of devotion, of unselfishness, of service? But this was not, and never had been, confined to doctors and their craft. That same instinct of self-control, of inhibition of the lower impulses, showed itself alike in the stoical North American Indian, the Samurai of Japan—Bushido—in the English public school man, in the Presbyterian Scottish forebears, and in the Greek philosophers.

Conclusion and Summary.

The lecturer, summing up his argument, said that the family doctor might be looked upon as the inheritor and curator of the truth that medicine had a corpus of its own, which must not be allowed to become a mere congeries of specialties; that in this territory he had a sphere of activity all his own, in which he might find freedom from the paralysing influence of officialdom. In this scheme of things there was but little room for self, but plenty of scope for service. Width of culture, keenness in work, depth of sympathy with the needs of poor humanity, such were his aims. They were those of Alexander Black, in memory of whom these words were spoken—in memory of a scholar of refinement, who for his living pursued the art and craft of medicine.

Thus one arrived at a vision of the family doctor. He was the heir of all ages, of Hippocrates and before him; with them he inhabited the main road on which the advance of medicine was journeying. It was his to travel on lines where he was nearer to the heart of humanity than any but his ancient ally the minister of religion; like him he sees things and feels experiences known only to them and to the people in whose homes he knows of deeds of quiet heroism, of suffering borne in silence, of self-sacrifice, of many things not published to the world. He saluted with reverence the spirit of humanity, for he knew, because he had seen, that that spirit was stronger than the pains and troubles of this mortal life; that there was nothing, not pain, nor hunger, nor weariness, nor the haunting dread of death and the invisible, that the spirit of man would not surmount and find itself the conqueror, not once and now, but always, and to the end.

LONDON AND COUNTIES MEDICAL PROTECTION SOCIETY.

ANNUAL GENERAL MEETING.

THE annual general meeting of the London and Counties Medical Protection Society was held at Victory House, Leicester Square, London, on June 8th, with Sir JOHN ROSE BRADFORD, president of the society, in the chair.

In submitting the annual report Sir John Rose Bradford said that the work of the society had increased, not only in respect to the actual number of cases coming forward for advice and assistance, but in respect also to the gravity of many of them, especially during the last year. Some of the cases involved very serious possible consequences to the members concerned, and he did not think he was exaggerating when he said that these cases, however anxious they might have been, had been dealt with by the society very successfully and in a manner entirely satisfactory to the members. In some now celebrated cases he believed that the society would be looked upon in time to come as having played a very noteworthy part, not only in the interests of the individual practitioner who happened to be implicated, but in those of the profession as a whole. He doubted whether the profession at present realized the debt which it owed to the society in that respect, for what the society had done could only have been done by a body which had on the one hand available the skill of competent legal advisers, and on the other the necessary financial stability, thanks to the care of treasurers past and present in husbanding the financial resources. The membership of the society had considerably increased, and now stood at about 10,000. This was a considerable figure, but even when the membership of the sister society was added it was evident that a very large proportion of members of the profession had neglected to avail themselves of the protection afforded at so small a cost. He also emphasized the necessity that a member, involved in anything which was likely to lead to litigation, should lay the case before the society at the earliest possible moment, instead of taking action on his own account.

The report was unanimously adopted, and with many expressions of appreciation for their past services the retiring officers and members of council were all re-elected, the officers being Sir John Rose Bradford (President), seventeen Vice-Presidents, Dr. C. M. Fegen (Treasurer), Dr. Hugh Woods (General Secretary), Mr. A. G. R. Foulerton (Financial Secretary), and the solicitors and auditors.

An extraordinary general meeting followed for the purpose of making some alterations in the articles, the principal of which was the insertion of a new article: "Additional benefits or special indemnity may be offered to members on such terms and in return for such extra payment or subscription as the council may from time to time prescribe." Sir JOHN ROSE BRADFORD explained that this alteration was necessary owing to certain additional benefits which the society, together with the Medical Defence Union, were proposing to give to their members. It had reference more especially to the principal's responsibility for the acts of an assistant who was not a member of a defence society. By paying an increased subscription of 10s. for each such assistant the principal was enabled to secure this protection. It was not quite clear under the existing articles of association whether the council had power to do this, and, therefore, it was proposed that this change should be made to put the permissibility of these additional benefits beyond question. The alteration was agreed to.

The annual report of the council stated that 1,057 new members had been elected during the year, including 355 who, joining the society within one year of registering, were exempt from the entrance fee. The number of applications for advice and assistance from members was 961, as compared with 801 for 1925 and 785 for 1924. In a large majority of the cases satisfactory results were obtained without litigation, and the results of most of the cases in which litigation occurred were also satisfactory. The council had continued to make provision, by special insurance, for an unlimited amount, to defray damages awarded against members, together with the costs allowed to the other side, in actions which the society undertook for members which were not successful. No claim had yet been made upon the society's insurers, but it was considered necessary to be safeguarded against all possible contingencies. The financial statement showed a reserve fund standing at £9,549, an insurance fund standing at £29,720, and a general fund at £1,333.

A very interesting solicitors' report and an abstract of cases dealt with by the society during the year were appended. The solicitors (Messrs. Le Brasseur and Oakley) stated that the past year was marked by the first defence in respect of a capital criminal charge which the society, since its commencement, had been called on to undertake. The gravity of this case, when first before the society, was immediately appreciated, and prompt steps were taken for the protection of one of the two doctors concerned. The other at that stage, not realizing the gravity of his position, had not then applied to the society. On the face of the depositions the case appeared to present difficulties, but after very careful investigation and consideration the society was satisfied as to the innocence of both its members. The solicitors were given an open hand to seek such expert advice as they required; through this, and the individual consideration by members of the council, the acquittal of both members was secured.

England and Wales.

LONDON WATER IN 1926.

SIR ALEXANDER HOUSTON has issued his twenty-first annual report on London water; it deals with the twelve months ended December 31st, 1926. He begins with an account of Kent and its wells, which rivals in charm the description of the New River contained in his twentieth report. Kent's contribution to the water supply of London amounts to one-tenth of the whole. It is drawn from twenty-four deep wells, which yield a daily average of 27 million gallons, enough for a town of the size of Manchester. The water is clear, of exceptional purity, and cool in the hottest weather. During 1926 the average bacterial counts from the wells were 9 per c.cm. on gelatin and 0.05 on agar, with *B. coli* absent from 100 c.cm. in 94 per cent. of samples. The chemical analyses were not less commendable. The average figure for ammoniacal nitrogen was 0.0002 parts per 100,000, for albuminoid nitrogen 0.0023, and for oxidized nitrogen 0.6. Hardness, on the other hand, as might be expected, was high, but was mainly temporary. The water of the Deptford Garden Well had come under notice last year as harbouring a pathogenic leptospira. No obvious explanation for this unprecedented occurrence presented itself. The well, as a precaution, was chlorinated for a time, but, as the untreated water remained free of virulent leptospirae, chlorination has been discontinued. This section of the report is illustrated by a photograph of the well. The report includes, in addition, many other photographs of well-houses, river reaches, and features of interest, which amply justify, if justification were necessary, Sir Alexander's cordial feeling for "Kent, the garden of England." The chlorination of Thames water was begun in 1916, and about two million people have, with some intermissions, been supplied with 76 million gallons of chlorinated water daily; no complaint of a taste has been made. During 1926 the bacterial record for Staines and Hampton together showed *B. coli* absent from 100 c.cm. of chlorinated water in 53 per cent. of samples. Chlorination, which was begun as a war-time emergency measure to save the coal which would otherwise have been consumed in the continuous pumping of Thames water through the Staines reservoirs, remained in operation afterwards on its merits. Some 25,000 million gallons were chlorinated in 1926, at an average dose of 0.35 parts of chlorine per million and a cost for chemicals of one shilling per million gallons. The net saving on coal was £14,872. The bacteriological state of prefiltration waters was carefully noted, as in previous years, and the improvement in quality of raw waters after storage was consistently observed.

The Barn Elms experiments continue. Work has been carried on with a view to determining, in the case of stored water, the results of rapid filtration without coagulants at a rate of over 134 gallons per square foot per hour, followed by slow sand filtration through filter-bed No. 18 at three times the normal speed. The results were judged by the quality of the final filtrate, the output between

cleanings of filter-bed No. 18, and any progressive reduction in this figure. The first of these criteria has reference to health; the second and third are economic. It was found that in the final filtrate *B. coli* was absent from 100 c.cm. of water in 81 per cent. of the samples tested; the standard was as high as by ordinary slow sand filtration at one-third the speed. The average output of filter-bed No. 18 per acre cleaned was 207 million gallons, more than twice the amount by ordinary slow sand filtration. The quantity fluctuated to some extent during the period of observation, but there was no progressive tendency to choking. These are distinctive findings. The Walton works, opened by Mr. Neville Chamberlain in July, 1926, are apparently being run on lines suggested by the Barn Elms experiments.

An investigation was made of 1,000 lactose-negative colonies showing colourless on rebipelagar in course of routine examinations of water, with a view to determining their possible kinship with pathogenic strains. Of the 1,000 colonies picked off, 135 turned out to be lactose fermenters and none of the remaining 865 gave the reactions of the typhoid, Salmonella, or dysentery groups.

Among topics of general interest commented upon in the report, which is the first of the series to be based on the calendar year, are the iodization of water supplies in order to control goitre, the Poplar outbreak of water-borne gastro-enteritis (JOURNAL, May 14th, p. 889), and super-chlorination followed by dechlorination as applied at Toronto to Lake Ontario water.

RADIOLOGICAL DEPARTMENT AT NEWTON ABBOT HOSPITAL.

The Prince of Wales visited Newton Abbot on June 7th to open two new wings which have been added to the hospital, at a cost of £16,000, for the more effective treatment of cancer. Dr. Edgar Haydon, senior medical officer, presented an address, in which he mentioned that this hospital was the second in England to be endowed with a stock of radium for the treatment of malignant disease. In consequence of this the number of patients received had been increasing each year, and the present enlargement had become urgently necessary. Mr. Sampson Handley attended a banquet at Newton Abbot in the evening in commemoration of the occasion, and commented on the great need for the provision of such treatment for cancer. Dr. Haydon stated that towards the cost of the extension £14,000 had already been raised, and it was hoped that the remainder of the sum might be obtained during the next six months.

DEWSBURY SANATORIUM.

The new Dewsbury Sanatorium, at Whitley Grange, which was opened on May 24th, is built in the pavilion style and provides accommodation for thirty beds, wings for the two sexes being separated by a central administration block. Five double-bed and five single-bed wards are provided for each sex. An open verandah, facing south-east, runs the whole length of the wards, and is covered by a glass roof. Asphalt paths have been constructed round the outside of the wards, and a roadway gives access to the land behind the sanatorium; the nurses' home has been extended. The cost of the new buildings was £7,610. The old wooden wards, previously used for treatment, will now serve as recreation rooms.

Scotland.

CARE OF THE BLIND IN SCOTLAND.

THE annual conference of the Scottish National Federation of Institutions for the Blind opened at Inverness on June 9th. Delegates were present from all parts of Scotland, representing institutions where the education and training of the blind are conducted. Dr. George Mackay, Edinburgh, in a paper on the welfare of the blind from an ophthalmic surgeon's point of view, spoke of the importance of securing the normal development of an organ which must be ready to function from the moment of birth. The early acquisition of clear fixation and of directional experience was required as a stimulus for visual development, and to prevent uncontrollable nystagmus throughout life. Congenital malformations were, he said, responsible for a certain proportion of blind children, but as similar defects occurred in the lower animals, these could not be assigned to blameworthy parental actions. The danger to the eyes at birth from injury or purulent infection was mentioned; though ophthalmia neonatorum was decreasing, constant vigilance must still be maintained. Many eyes were hopelessly scarred in childhood by recurrent attacks of phlyctenular keratitis in weakly children, who suffered also from decayed teeth, septic tonsils, adenoids, and a general want of resistance to the tubercle bacillus. Proper feeding, sufficient air, and sunlight were necessary to prevent the occurrence of such conditions. The proportion of admissions to blind asylums resulting from inherited syphilis was relatively large; the facilities which were now offered for treatment by public authorities could not fail, however, to lessen the incidence of this disease, and were undoubtedly diminishing the severity of its manifestations. Among the other causes which contributed to the ranks of the blind were glaucoma, optic atrophy, detachment of the retina, atrophy of the choroid with or without high myopia, degenerative changes affecting the retinal pigment cells, and haemorrhages into the eye or brain associated with high blood pressure. Blindness from accidents varied in frequency in different parts of the country according to the main industries followed. Leprosy and small-pox as causes of blindness had practically disappeared in this country, and trachoma or granular conjunctivitis was rare save among alien immigrants, notably Irishmen, Poles, Germans, and Russian Jews. Dr. A. Freeland Fergus, Glasgow, in commenting upon Dr. Mackay's paper, said that an arrangement ought to be made whereby every blind person in the country could have the benefit of the advice of a reliable ophthalmic surgeon. A discussion on the mentally defective and inefficient blind was opened by Mr. George Danby of the Royal Glasgow Asylum for the Blind, who said that the problem urgently called for attention; while it was agreed that marriage of the physically and mentally fit blind person was to be encouraged, the union of a person mentally defective as well as blind was to be deplored. He gave a general idea of the work and training that could be accomplished in a home provided for blind mental defectives. The report of the directors of the Royal Blind Asylum and School, Edinburgh, for the year to March 31st, stated that though the workshops of the institution had passed through a year of great trade depression the directors were able to give a satisfactory report on new agencies established by them in the south of Scotland, which had brought a considerable increase of new business to the institution, through the establishment of motor transport. The number of blind persons undergoing technical training had increased to seventy-nine. At the sixty-seventh annual meeting of the Mission to the Outdoor Blind for Glasgow, the Lord Provost, who presided, said that it took a very high place among the practical and benevolent work of the city. At the annual meeting of the Dundee Mission it was reported that the number of blind on the register was 365—116 males and 249 females—an increase of 11 on the previous year. Mr. S. G. Fraser, convener of the public health committee, moving the adoption of the report, said that for the last three years in Dundee there had been only one case of a child in whom ophthalmia neonatorum had caused loss of eyesight.

VITAL STATISTICS OF THE FIRST QUARTER.

The report of the Registrar-General for Scotland on the births, deaths, and marriages registered during the quarter ended March 31st, 1927, shows that the more outstanding features of the vital statistics during the period were a birth rate of 20.5 per 1,000, a marriage rate of 6.1, and a death rate of 16.1. The birth rate is 2.4 less than the average, the marriage rate 0.3 less than the average, but the death rate, though higher than in the previous quarter or in the first quarter of last year, is 0.8 below the mean of the first quarters of the preceding five years. The infantile mortality rate of the quarter was 110 per 1,000 births, which is 5 less than the mean for the first quarters of the previous five years. The deaths from malignant disease were 1,671, equal to a death rate of 138 per 100,000, being 17 more than in the previous quarter and 45 more than in the first quarter of last year. The death rates

from all forms of tuberculosis and from tuberculosis of the respiratory system were 109 and 77 per 100,000 respectively, both lower than in the first quarter of last year. Deaths from influenza numbered 1,274, and equalled a death rate of 106 per 100,000. This number is 1,062 more than in the previous quarter, and 945 more than in the first quarter of last year. It goes far to explain the slight increase in the general death rate for the quarter. For the principal towns the highest influenza death rates were in Kilmarnock, Dunfermline, and Perth, and the lowest in Clydebank, Ayr, and Glasgow. The rates in Edinburgh, Dundee, and Aberdeen occupied a middle position. No deaths from small-pox are recorded, but 3 died of enteric fever, 152 of diphtheria, 25 of encephalitis lethargica, and 30 of cerebro-spinal meningitis. Deaths from diseases and accidents of pregnancy and childbirth numbered 151, which is 33 less than in the first quarter of last year.

AMERICAN DOCTORS' VISIT TO EDINBURGH.

The Inter-State Post-Graduate Assembly of North America paid a visit to the Edinburgh Medical School on June 6th and 7th. The party numbered 120. At the Royal Infirmary a demonstration of radiological appliances and work was given in the x-ray department, clinics were held in various wards, and operations performed in the surgical theatres. A small party of the visitors also attended clinics in the Royal Hospital for Sick Children. In the afternoon a lecture was delivered by Professor Sir E. Sharpey-Schafer on the relationship of physiology to medicine and surgery. This was followed by a lecture on the history of medicine and surgery in Edinburgh, by Dr. J. D. Comrie. Later the visitors were present at the Cameron Prize Lecture, by Dr. H. H. Dale, entitled "The nature of the action of insulin," and a party was conducted round the Museum of the Royal College of Surgeons by Mr. D. M. Greig, the conservator. On the afternoon of June 7th the party left for Newcastle to embark for Bergen for a tour of the medical schools on the Continent.

India.

INDIAN SCIENCE CONGRESS, 1928.

THE fifteenth annual Indian Science Congress will be held in Calcutta from January 2nd to 7th, 1928. In view of the meeting in this city in the previous month of the seventh Congress of the Far Eastern Association of Tropical Medicine, to which we referred on May 21st (p. 944), some doubt has arisen as to the advisability of proceeding with the arrangements for the medical section of the Indian Science Congress, since a certain degree of overlapping would appear to be inevitable. In the circumstances an attempt is being made to find out from medical practitioners in India whether meetings of the medical section of the Indian Science Congress should be abandoned on this occasion, or whether enough support will be forthcoming to ensure successful meetings being held. It is fully recognized that the first duty of the medical profession in India is to the Congress of the Far Eastern Association, and that an obligation is laid on India to uphold her status in the sphere of tropical medicine which is not bounded by limitations of nationality. It is possible, however, that sufficient promises of support and offers of medical and scientific papers will be received to justify arrangements being made to hold meetings of the medical section of the Indian Science Congress.

FILARIASIS IN INDIA.

At the Indian Science Congress held at Lahore last January, Lieut.-Colonel Sir Frank Connor, I.M.S., professor of surgery at Calcutta Medical College, pleaded for a thorough investigation of the filariasis problem, with special reference to the condition in India. At present no organized attempt is apparently being made to deal with a disease which is causing great suffering to many of the inhabitants of India, China, parts of Southern Europe, the Pacific Islands, Australia, and the West Indies. Sir Frank Connor, whose address to the congress is published the May issue of the *Indian Medical Gazette*, draws attention to the serious gaps in our knowledge of this infection. Little information exists about the stages which follow the entry into the human host of the microfilariae from the mosquito, and about the way in which the adult worms destroy and obstruct the lymphatic vessels. Other investigations which are urgently necessary include the study of the nature of filarial fever, the details of the varying types of lymphatic obstruction, and the etiology of tropical hydroceles. Sir Frank Connor considers that a mosquito survey is essential, with special reference to the varying incidence of filariasis. He advocates the appointment of a special commission to correlate existing sporadic researches and to solve the problems of prevention and treatment.

MEDICAL AID FOR WOMEN IN INDIA.

Three annual reports for 1926 of organizations of which Lady Irwin is president have been issued in one volume. These organizations are the National Association for Supplying Medical aid by Women to the Women of India, which incorporates the Countess of Dufferin's Fund and the Women's Medical Service; the Victoria Memorial Scholarships Fund; and the Lady Chelmsford All-India League for Maternity and Child Welfare. The National Association, founded in 1885, devotes its funds chiefly to the medical training of Indian women; it also gives grants to hospitals for women in various parts of India. In its forty-second annual report it is stated that there are 256 women medical students at present, of whom 105 are attached to the Lady Hardinge Medical College at Delhi. At the hospital in connexion with this college Lady Reading opened, in March, 1926, a new unit of sixty beds, including accommodation for sick students and nurses, an x-ray department, and five single rooms for paying patients. The number of in-patients in 1926 was 3,867, as compared with 3,012 in the previous year, and the out-patient department dealt with 11,670 cases. The electro-therapeutic department was extended during the year under review by the addition of apparatus for high frequency and diathermy work. The Dufferin Fund has assisted in the erection of a new home for nurses at the Victoria Zenana Hospital at Delhi; this will enable further accommodation to be provided for paying patients. The Dufferin hospitals in Shikarpur, Hyderabad (Sind), Karachi, Calcutta, and elsewhere have increased their activities. The building of the new hospital at Nagpur is proceeding satisfactorily, and the opening of the new maternity blocks in connexion with the hospital at Cawnpore has resulted in a notable increase in the number of in-patients and maternity cases. A new operating theatre was opened at the Lady Elgin Zenana Hospital at Gaya, in July, 1926. The Lady Chelmsford League has given considerable assistance to the health schools at Delhi, Lahore, Madras, and Calcutta. The Delhi health school, now known as the Lady Reading Health School, has obtained new quarters, comprising several rooms for ante-natal work, consultations, the treatment of minor ailments, an observation ward, a classroom, and two bath-rooms. The building is situated in a congested area, and the health visitors under training at the school have ample facility for the study of home conditions. Two new subjects have been added to the curriculum—namely, vaccination and child psychology. The demand on the Lady Chelmsford League for trained health workers is far in excess of the present supply, and with a view to obtaining more students it is proposed to increase the number of scholarships for the preliminary midwifery course. The Lahore health school, previously controlled by the Lady Chelmsford League, is now being taken over by the Punjab Government. Additional schools for the training of health visitors are in existence at Poona and Nagpur; in both cases special emphasis is laid on practical work. The Lady Chelmsford League assists a large number of maternity and child welfare centres, including those at Simla, Dera Ismail Khan, Rajputana, Bangalore, and Madras. The travelling exhibition of the League visited numerous large towns during last year, and various pamphlets on health subjects were printed and distributed. A new cinematograph film illustrating child welfare work in Delhi has proved very popular.

Correspondence.

DRUGS FOR SLEEPLESSNESS.

SIR,—While feeling that Sir Maurice Craig's statement that sleeplessness is one of the commonest causes of mental illness is very debatable, and believing that insomnia is nearly always a symptom and seldom if ever a primary cause of serious mental disorder, I am chiefly concerned to deal with the views of Sir William Willcox, who implies that the barbitone hypnotics are to be classed as dangerous drugs. It is true that if sleeplessness be regarded as a symptom rather than a cause of mental illness the barbitone group can no longer be looked upon as sovereign prophylactics; but there remain definite indications for their use, which it would be a pity to hamper unnecessarily. Yet if the arguments of Sir William Willcox are accepted, their effect will be to limit the usefulness of these hypnotics seriously indeed. He bases his statements on clinical and on experimental grounds. Evidently as a toxicologist he becomes a victim of errors of sampling, and sees principally those patients who have abused the hypnotics prescribed for them. On the basis of considerable experience of medinal (now the most widely used of the barbitone hypnotics) in my own hands and in those of colleagues, I have no hesitation in saying that where a proper discretion is exercised in the choice of patient, serious toxic symptoms with the usual medicinal doses (5 to 10 grains), even when long continued, are rare; that they are attributable to other factors such as idiosyncrasy; and that they are rapidly recovered from. Medinal is not in the majority of cases a cumulative poison in ordinary doses to the human adult.

The experimental evidence quoted by Sir William Willcox is founded largely upon an article by the late Sir F. W. Mott and Drs. Woodhouse and Pickworth in the *British Journal of Experimental Pathology*. The experimental results, while admirable in themselves, will not for a moment stand the application which Sir William Willcox seeks to give them. The objections are as follow. (Cats and monkeys were used for the experiments.)

(1) Cats at least were unsuitable subjects. The most careful observation failed to detect any trace of sleep in them after doses, however large.

(2) The doses used were disproportionate to those given in man. The weight of the cats ranged from 600 to 2,000 grams. Five- or ten-grain doses were given daily. Taking the average human adult as weighing 70 kg., the equivalent dose in man would be from 600 to 1,200 grains—*enough to kill ten or twenty men*. And the equivalent of these doses was given in a single day. Some of the animals received in the course of treatment as much as 600 grains, which is the proportionate equivalent of 70,000 grains in man. No one denies that medinal in excessive doses is dangerous or even lethal.

(3) The animals were seldom allowed to recover from these enormous doses, but were usually killed at once; although it was noted that in animals allowed to recover even "after an advanced stage of drug treatment" the activity and intelligence returned to normal in ten to fourteen days. If the animals were then killed, little or no histological change could be detected in the central nervous system (and this in a cat treated for forty-eight days with doses of 2½ to 5 grains a day—the human equivalent of 87 to 175 grains a day, making in 7 weeks a total of 4,200 to 8,400 grains).

It is clear that such experiments have little clinical application, except to show that the members of the barbitone group are remarkably harmless to the central nervous system. The clinician must decide what latitude to allow a patient in the matter of hypnotics. In any case the drug should be regarded only as a symptomatic remedy, to be used while an attempt is made to discover the underlying causes. If there is any doubt in a given patient, the suggestion of a German physician, that a small dose of pulv. ipecac. be combined with each prescribed dose of medinal, would ensure that with a lethal dose of medinal would go also an emetic dose of ipecacuanha.—I am, etc.,

London, W.1, June 9th. R. D. GILLESPIE.

SIR,—The causes of sleeplessness are so varied, the physique and the mentality of the sufferers so different, that there is probably justification for the divergent opinions expressed by those who advocate and those who oppose the prolonged use of drugs. The type of case met with by Sir Maurice Craig is not that seen frequently by the average medical man.

I have met with only one patient who seemed none the worse for having taken some form of sleeping draught three or four nights a week for twenty years. She was a robustly built lady over 60, who never had to use her brain for any purpose. The cause of her sleeplessness, when I saw her, was intestinal flatulence; with treatment for this condition she reduced the drug-taking to twice a week. She could not break the habit; nor did she wish to do so. Perhaps she was right in her opinion that drugs were harmless when she had no worries and did not need to use her brain.

It would be disastrous were drugs regarded as safe for the average case of insomnia in brain workers. We require first-hand evidence from the normal person engaged in business or the practice of a profession. Attacks of sleeplessness may arise from such causes as overwork, worry, financial or emotional overstrain, or from an easily overlooked source of chronic toxaemia. The incessant noise of street traffic aggravates the condition, and the insomnia becomes habitual. What is the effect of drugs in those cases? If taken for a few nights the sleepless habit may be broken, the sufferer is refreshed and all is well. But is this the usual course of events? As a general rule the victim finds that the continuance of the drug is necessary; he is afraid to go to bed, dreading the hours of waiting for the sleep which will not come. The sleep obtained at length by drugs does not restore his fatigue; his mind is confused when prompt and accurate thought is demanded; his intellectual output is diminished and deteriorated; his relations with the external world and its values become altered; he becomes stupefied and profoundly depressed, hypersensitive, and hyperemotional. At this stage a long holiday is the sole remedy which will save the sufferer from a complete breakdown.

There is, however, a method by which sleeplessness may be effectually aided, and the habit broken if the patient is seen before drugs have been taken for long. I speak from limited experience of such patients, but also from personal experience of many occasions when work had to be done which demanded accuracy of thought during the day's routine. Weary of the stupefying effect of drugs, I remembered how Leduc had recommended for neurasthenia the passage of a galvanic current through the brain. The result of following his directions was so happy that ever since I have resorted to his method, both for myself and my patients, with a confidence never betrayed. The current must be given by those accustomed to deal with electricity, as it is important to avoid shock. The electrodes must be properly padded; the negative pole placed over the forehead; the current turned on and off very slowly. Leduc used to give 20 m.a.; I find 5 to 10 m.a. for fifteen to twenty minutes is sufficient; many people cannot stand more. The immediate effect is a lightening of the feeling of tension and stupefaction, a speeding up of thought processes. When night comes the brain is no longer too tired to sleep; sleep comes naturally and is refreshing. Often one treatment is all that is needed to break a bout of insomnia which threatens to become serious.—I am, etc.,

London, W.1, June 7th. AGNES SAVILL.

SIR,—There is no question that in certain forms of mental disease it is necessary to use drugs to procure sleep and relief from mental pain, and that in acute illness the occasional use of veronal and medinal is justified. But I must support Sir William Willcox when he condemns the use of barbituric compounds, unless the patient is under continual medical supervision.

Addiction to veronal undoubtedly exists. I know of two cases. One, a man of 40, perfectly normal until he was given medinal for eight weeks on end, during and after an attack of influenza. Since then he has tried to give it up, but is unable to do so. Without it, to use his own words, he is "incapable of mental concentration and so irritable that work becomes impossible." The other case is a woman of 35, apparently suffering from some form of auto-intoxication, of which insomnia is one of the manifestations. This is a case where physiotherapy should have been tried before hypnotics were resorted to—the kind of

case in which colon douching, diathermy, ultra-violet light, combined with tepid (Priesnitz) abdominal compresses and judicious massage, often give very good results. Unfortunately medinal only was prescribed, and the patient has taken it for five years, first in 5, then in 7, now in 10-grain doses. There is distinct evidence of mental deterioration, which her husband and family ascribe to the drug. He has begged her to give it up; but to stop it, he says, makes her unutterably miserable, and so depressed that he has given up all opposition. "Besides, what can I do when she is assured that it is harmless?"—I am, etc.,

JUSTINA WILSON, M.R.C.P.Edin.

London, W.1, June 6th.

SIR,—Many patients who have been referred to me by their doctors for nasal obstruction have suffered for long periods from sleeplessness, and I have elicited the fact that often for years they have been taking such a drug as medinal in order to obtain anything like a good night. I have never heard of any ill effects, but only of how beneficial and indispensable this drug has been.

It is not sufficiently recognized how commonly nasal obstruction is present in varying degree, and always aggravated on lying down, in those complaining of want of sleep; this is easily explained, since any interference with clear nasal breathing leads to brain congestion, which is inimical to repose. The sure cure of many a be-drugged sufferer is by way of a nasal operation, such as septal resection, or submucous turbinectomy skilfully performed.

I have notes of numerous patients who have taken dial and medinal in small and moderate doses over long periods, originally prescribed by physicians or doctors for erratic sleep, but in none has there ever been established any marked addiction or habit.—I am, etc.

London, W.1, June 7th WM. STUART-LOW, F.R.C.S.

SIR,—Sir William Willcox's warning about the dangers of the barbital group of sedatives is timely, for I find in the minds of many practitioners, besides myself, an uneasy feeling that the claims made as to their harmlessness are extravagant. The two following distressing cases have occurred recently within my own experience.

A man, aged about 50, had been taking one or other of these drugs at irregular intervals for a year or two, and probably more of late. He began with what appeared to be influenza, followed in a fortnight by pneumonia beginning in the right middle lobe. This cleared up, but for the greater part of a month he was practically unconscious, and had incontinence of both urine and faeces. His condition was at that time diagnosed by "competent authority" as encephalitis lethargica. He eventually recovered, and for the last month has shown no mental or moral deterioration, but only physical weakness, which is rapidly improving.

The second case was a man, aged about 70 years, who had had another preparation of the same group with fair frequency for four months. He has now been frightened into refusing it, because twice he has awakened in the night after it to find himself with the urinal in bed and the bedding all soaked.

Whether this is due to a half-unconsciousness (it had always acted well previously) or to poisoning of the centres I cannot say, but it has been distressing and alarming enough to cause distrust of these much vaunted preparations.—I am, etc.,

Leigh, Lancs, June 6th. JOSEPH JONES, M.D.

SIR,—The following case of addiction to drugs of the barbituric acid group is of interest.

An unmarried woman, aged 40 (British), who suffered from chronic infection of both antra, following operations on the nasal septum for the relief of asthma. She was otherwise physically strong, and was mentally normal. She was holding a position of responsibility and trust up to a few weeks of her death. The toxaemia from focal infection caused restlessness and insomnia, and for four years veronal (diethyl barbituric acid) was prescribed, in various countries, for the relief of insomnia. Twelve months before her death the following symptoms, in this order, appeared: (1) increasing restlessness and insomnia; (2) mental worry; (3) thick, indistinct, slurred speech; (4) urticarial eruption, with itching of the skin, especially of the legs; (5) headaches, and many other subjective symptoms—for example, that her "head was made of cotton-wool," and was "buzzing round inside"; (6) vertigo, with the feeling that stationary objects were moving round her; (7) nausea; (8) irritability and depression; (9) diplopia and indistinct vision, following larger doses; (10) ataxic gait, with dragging of the feet and difficulty in walking upstairs; at times reeling and staggering gait, so that the patient walked with the aid of two sticks; (11) conjunctivitis and inflammation of the eyelids, which have been frequently recorded in veronalism. The patient experienced a sense of well-being and temporary relief from restlessness after taking the drug, and found she could not give it up.

In April, 1925, she entered a nursing home in London and was prescribed 10 grains of medinal (sodium veronal) and 10 grains of aspirin at night, for the relief of headache, pain in the left eye, and insomnia. After the dose had been given the patient took a dose of somnifène (isopropyl propenylbarbiturate of diethylamine), which had been prescribed abroad, in place of veronal, several weeks previously (20 to 30 minims somnifène=5 grains of veronal).

Next morning she was found to be comatose, with the breathing stertorous and of Cheyne-Stokes type. Raised temperature, feeble pulse, and cyanosis occurred, the symptoms leading to the suspicion of a cerebral lesion. Before the onset of the acute symptoms the condition had been treated as post-influenzal functional neurosis.

Pus from both antra discharged down the nostrils shortly before death, which occurred about twenty-six hours after medinal had been given. The time at which the patient took somnifène is not known.

Post-mortem examination showed no organic lesion, but signs of pneumonia. The amount of veronal found on analysis in the various organs was: liver 2.5 grains, urine 7.8 grains, stomach and contents 0.8 grain, kidneys 1 grain—total 12.1 grains.

The estimated total dose taken was 50 to 100 grains of veronal. The verdict at the inquest was "Death from an overdose of veronal." This was clearly a case of chronic veronal poisoning following addiction, and terminating in a fatal overdose.—I am, etc.,

London, W.1, June 4th. H. YOUNG.

SIR,—Sir William Willcox takes exception to my criticizing his paper before it is published in full, but he does not say that the report which was published in the BRITISH MEDICAL JOURNAL of May 14th (p. 877) was in any way incorrect. He was reported as having made very definite statements regarding the barbitone group, and it was these statements which seemed to me to call for comment, as I felt that the great therapeutic value of these drugs was being jeopardized by the emphasis that Sir William Willcox laid upon what he regarded as the danger attached to their use.

The argument from the use of these drugs for self-destruction does not seem a very strong one, as, even if the numbers were far greater than those given by Sir William Willcox, there is nothing to show that these persons would not have destroyed themselves by some other means, as indeed they almost certainly would; while to say that, if a patient who has been taking medinal regularly on medical advice takes his life, this is the result of the medinal and not an act resulting from the condition for which the drug was given seems to me quite indefensible. Sir William Willcox states that, a patient having taken 10 grains of veronal every night on medical prescription, "*this caused*" (the italics are mine) "mental depression, leading her to take 10 ounces of pure lysol with fatal result." I presume that the patient in question was taking the veronal for sleeplessness, which is a common cause of depression, therefore why conclude that the veronal was the active factor in bringing about the depression? Again, he records another case of a patient who had been taking a daily dose of 5 grains of medinal over a long period. "*This culminated*" (again the italics are mine) "in her taking forty powders at once with fatal result." The reasoning here does not seem quite without bias. Why "culminated" when the lady *seems to have* been satisfied to take the 5 grains regularly for a long period? This case bears a strong resemblance to that reported by Dr. L. S. Woolf in his letter of the same issue, but Dr. Woolf seems less convinced of the part that the drug had played, and this would seem the more scientific attitude.

Sir William Willcox says that, as addiction is only discovered when the drug is withheld, I do not know whether my patients become addicts or not, but if he would refer to my letter he would see that I stated that I always found it quite easy to discontinue the drugs even after long periods. Except in very rare cases, and these in the types to which I referred, I have found no addiction, and this is borne out by the experience of many medical men whom I have questioned on this subject. If addiction is so likely to occur, it would be interesting to hear where these

addicts are, and what they are doing. Neither I nor, from inquiry, most of my colleagues and many general practitioners see them. Addicts to any drug are usually seen by a number of medical men, as the condition is a chronic one, and from experience I have found that the same patient is frequently on the list of many physicians.

Sir William Willcox emphasizes the deterioration he has observed in those taking the drugs in question. On the other hand, Dr. E. Goodall, writing on the luminal treatment of epilepsy in the Cardiff Mental Hospital, says: "Very gratifying results have been obtained by the administration of sodium luminal to epileptics. It arrests the attacks, especially the grand mal, and has no deleterious effect on the physical and mental conditions of the patient, as have the bromides and allied drugs."

I have read the paper in the *British Journal of Experimental Pathology* quoted by Sir William Willcox. The research work for this paper was carried out on cats and monkeys, and the drugs employed were sulphonal, trional, and the barbitone group. As to the toxicity of the two former, I am fully in agreement; I have seen all the physical signs reported, and it is for this reason that I seldom use these drugs, but this question is not at the moment under discussion. With regard to the barbitone group, it is stated in this paper that they do not induce sleep in cats, so that at the very outset it is clear that these drugs act on cats in quite a different way from the effect they have on human beings. But more remarkable still, in view of the facts, is it that this piece of research should be adduced as having any bearing on the effects of these drugs when given to human beings in therapeutic doses. In these experiments cats weighing 600 to 1,000 grams were given 5- to 10-grain doses of veronal, in a few instances beginning with 2½ grains. Taking an average man at 70 kilos—that is, 70,000 grams—to make the dosage comparable he would be taking 400 or 500 grains. The monkeys weighed 5 lb., and were given 5 to 10 grains of veronal, the comparable dose for a man being 140 grains. The writers of the paper state, "The barbitone group of drugs showed similar but less pronounced exhaustion effects (than sulphonal and trional) and it was found that veronal and dial could be given to cats for many days without appreciably impairing the general well-being of the animals." If the barbituric acid group are as dangerous as Sir William Willcox believes, the marvel is that they survived at all.

I still await any proof that these drugs, given in therapeutic doses even over a long period, are harmful or cause any ill effects other than the simple rash at times produced in those who have an idiosyncrasy to them.—I am, etc.,

London, N.W.1, June 8th. MAURICE CRAIG.

P.S.—Through the courtesy of the Editor I have been permitted to see some of the other letters appearing in this issue. I should like to emphasize again that the opinion that I expressed in my letter in the issue of May 28th is based on long experience in treating normal persons of all ages in various activities of life. The physiologists tell us that sleep defective in quality or quantity leads to deterioration in the tissue cells of all organs, including the nervous system, and this is in accordance with clinical experience. Therefore it is incumbent upon the medical profession to treat defective sleep far more seriously than has been the custom in the past. My experience is that if a patient has been prescribed and is taking a sedative in the barbituric acid group and any untoward symptoms arise in the course of the illness, these are at once ascribed to the drug, whereas in truth the symptoms belong to the disorder for which the drug is being given and occur in persons who are not taking, and have never taken, any of these drugs. (Of course, I do not here include persons who have taken an improper dose for ulterior purposes.) All I am asking for is clearer thinking and closer observation. I was brought up to view sedatives in the same light as many of your correspondents, but in the struggle over many years to prevent and repair disease certain points begin to stand out clearly. I do not ask anyone to accept my experience or my conclusions; but, knowing how crippling and at times how devastating sleeplessness may be, one is compelled to examine every avenue to try to prevent its results. For doing this I have found over many years that the barbitone group afford the best results with the minimum of ill effects.—MAURICE CRAIG.

RHEUMATIC INFECTION IN CHILDREN.

SIR,—Dr. A. Dingwall Fordyce writes (June 11th, p. 1081) with so much friendly appreciation that the thought that he is "attempting to pick holes" is far from my mind, more especially as I do not think that there is any great disagreement between us if due allowance for the difference of approach to the problems of rheumatism is made.

Dr. Fordyce is at his ease studying the lights and shades of the rheumatic picture. Those with whom I was working were in a less enviable position. We were attempting to hew out certain facts which would serve as landmarks for those whom we hoped would come along to help in the prevention and control of the disease amongst the children of this country. Thus, his statement that "juvenile rheumatism under satisfactory conditions can usually be controlled" becomes our statement that juvenile rheumatism "is a disease of the poor." Allowing for the difference of outlook there is no great antagonism between the two views. Again, when both committees fail to find that heredity is an etiological factor of moment, we tended to stress the fact that we found no great hereditary predisposition such as would be a bar to successful prevention of the disease. Dr. Fordyce puts it that the evidence proves nothing for or against its importance. Even so, this is a point.

The only view expressed by Dr. Fordyce with which I do not really agree is his suggestion that potential cases of rheumatism are common in the well-to-do classes. Although I do not think that the difference in frequency amongst the rich and the poor is as great in the potential as in the declared cases of rheumatism, yet even with these in mind I should still regard juvenile rheumatism as a disease of the poor.

Dr. Fordyce's letter is at once so kind and yet so stimulating and thoughtful that in taking this line in reply I feel conscious of appearing brusque and unsympathetic. I trust he will be assured that with him I know that it is down the little by-paths that the interests lie, yet some at least must keep to the wearisome high road. I am, etc.,

London, W.1, June 11th. REGINALD MILLER.

THE CONSTITUTIONAL FACTOR IN DISEASE.

SIR,—I can assure Dr. Hurst (June 4th, p. 1032) that I quite understood his position and had given consideration to the four additional reasons stated in his letter. My purpose in entering a caveat against the too ready acceptance of his views was based on (1) the paucity of the available data; (2) the qualifications in the terms "almost always," "probably always," and "often," in the reasons set forth by Dr. Hurst in his letter, and (3) a consideration of the results of the researches of Dr. William Hunter on medical sepsis, which largely form the basis of our present knowledge of the anaemias with and without lesions in the nervous system. These have not yet received the recognition and study which their great importance demands.

Dr. Hurst has not replied to my request for precise information as to the tests he employed, and the results obtained from them, which satisfied him that he could exclude an alimentary toxaemia as an etiological factor in migraine. He has contented himself with the general statement that he has never found any abnormality by means of test meals, microscopical, chemical, and bacteriological examination of the stools, radiological examinations of the alimentary tract, etc. It is obvious that much depends on what is looked for, and on the views entertained as to what constitutes normal urine and stools, and in regard to this I rather think our views may be fundamentally different. He invites me to give him details of the investigations which have taught me that migraine is due to an alimentary toxaemia. This is not, strictly, my position. Alimentary toxaemia is in my view, one form, and a most

important one, of general medical sepsis, which often exists for a long time before revealing its presence. I find striking confirmation of this view in Dr. Hurst's lecture, in which he points out that "the bodies of about 10 per cent. of all people dying in adult life contain gall stones," and later that "cholecystitis is the only indisputable predisposing cause of gall stones." Other sources of medical sepsis demand equal consideration.

I can best give him the information desired by reference to a case of migraine of some years' duration admitted to my ward three days ago. As a matter of routine all the recognized sources of peripheral and central irritation will be explored, but in regard to the subject under discussion, I find the urine very turbid from the presence of bacteria and cells, a growth of *B. coli* forms a carefully collected catheter specimen, and by the use of a Plombiere douche after a preliminary enema to clear out the bowel, conclusive evidence, in the general appearance and pronounced fetor of the returned fluid, of an abnormally septic state of the bowel contents. My experience of these cases leads me to attach the greatest importance to the correction of these disorders, and this can be done without ignoring the influence of heredity and other possible etiological factors.

In recent years there has been a marked tendency in medical writings to belittle the existence of an alimentary toxaemia. In regard to this, it is reasonable to suggest that the remarkable developments of abdominal surgery in the past thirty years—more especially in relation to diseases of appendix, stomach, duodenum, and gall bladder—have some bearing on the point. The common surgical abdominal disorders are, in the main, end-results of an acute, subacute, or chronic septic process, and the necessity for the surgeon arises from the failure of the physician. There is good reason for thinking that the progress of medicine in the future will largely depend on our recognition of the profound importance of medical as opposed to surgical sepsis. The problems must be faced with an open mind, and it is probable that in the process a good deal of present medical teaching will require revision. I may be allowed to close by quoting a relevant extract from a lecture by Dr. Abernethy, delivered to the Royal College of Physicians in 1815, a lecture designed to explain some of John Hunter's opinions, which were, in Dr. Abernethy's opinion, receiving too tardy recognition from the profession at that time:

"May I venture to suggest another reason why some do not understand Mr. Hunter? If we wish to learn what another thinks, we must dispose our minds to receive instruction in the very manner it may be conveyed to us. We must relinquish, for a time, all attention to our own opinions, in order to learn those which are to be communicated. The same processes of mind must be gone through or the same results cannot be obtained; we must follow in exactly the same steps or we shall never arrive precisely at the same point. It is a very ancient observation that self-conceit opposes a constant and sometimes an insurmountable barrier to instruction."

—I am, etc.,

CHALMERS WATSON, M.D.

Edinburgh, June 5th.

PULMONARY EMBOLISM FOLLOWING FRACTURE OF LEG.

SIR,—Dr. Erskine Faraker's interesting account of fatal pulmonary embolism following a simple Pott's fracture (June 11th, p. 1056) raises again the question of where the thrombosis primarily takes place. His suggestion, that early massaging may be a factor in the causation of pulmonary embolism, implies the formation of the thrombus at the site of the lesion, but in our experience this is not necessarily so; clotting in many instances in all probability occurs in the great veins of the lower abdomen, particularly the inferior vena cava.

This is borne out by the fact that we have known pulmonary embolism occur: (*a*) following an uneventful cataract operation—fatal pulmonary embolism occurred eight days afterwards—this case is recorded by T. G. W. Parry in the BRITISH MEDICAL JOURNAL, October 10th, 1925; (*b*) following rest in bed for traumatic synovitis of the knee-joint; and also by the fact that (*c*) at the present time we have under observation a case of thrombosis of the inferior vena cava following appendicectomy nearly a year ago; fortunately the main clot has apparently organized and become adherent in the inferior cava, but this patient after operation had some pulmonary symptoms which conceivably were due to minute infarctions.

Our experience so far is in accord with that of Mr. Lockhart Mummery, who has written so ably on this question.

That pulmonary embolism may result from thrombosis at the site of injury is borne out by an instance which occurred following bruising of the femoral vein by manipulation of a dislocated hip. This case was recorded by A. W. Sheen in the BRITISH MEDICAL JOURNAL for November 22nd, 1924. Cases which occur following phlebitis, and the post-puerperal ones, are further instances of clotting at the site of the primary lesion.

It appears, therefore, that the thrombosis may occur (*a*) at the site of the lesion, (*b*) in the great veins of the abdomen. In our opinion, in the majority of cases, especially the post-operative and those following simple fractures or trivial injuries, the clot formation occurs in the great veins of the abdomen and away from the site of the lesion.

This question of where the clot forms is of importance, not only in so far as it concerns the pathogenesis of this distressing condition, but also because it concerns the question of treatment. If the primary lesion is the site of the thrombosis, early massage is contraindicated; on the other hand if stasis in the inferior cava is, as we believe, the site of the clot formation in the majority of cases, especially those following operation and simple fractures, early movements are desirable.—We are, etc.,

June 13th.

UROGENITAL TUBERCULOSIS.

SIR,—I am much interested in Mr. Nitch's favourable view of the value of tuberculin in renal tuberculosis (May 14th, p. 863) and also in Dr. Stavely Dick's comment and argument thereupon (June 11th, p. 1083).

Although in 1921 it was stated in an official report that I considered renal tuberculosis to be unsuitable for tuberculin treatment, my real views based upon experience, were stated in 1912, in my Weber-Parkes prize essay, pp. 109-110, as follows:

"In suspicious cases of chronic pyelitis or of renal trouble I have several times used the tuberculin test in diagnosis, and am astonished that so many writers, in discussing the diagnosis of renal tuberculosis, overlook the tuberculin test. Not only is tuberculin of very great value in the early diagnosis of renal tuberculosis, which so often runs a latent course even for years, but renal tuberculosis in my experience seems to be particularly amenable to tuberculin treatment. Unfortunately, troubles of the bladder and kidney, especially associated with pyuria, are supposed to belong to the domain of surgery, and I have found that surgeons especially look askance at tuberculin, so that I have seldom had opportunities of showing the value or otherwise of the tuberculin test in the early stages of renal tuberculosis. This field is only waiting to be explored by the searchlight of tuberculin, and I believe a rich harvest of results will be reaped thereby."

Moreover, in this essay I give four cases of advanced genito-urinary tuberculosis treated with tuberculin, one of them (p. 315, No. 3) with phenomenal success—the other three with considerable success. Since 1912 I have treated many cases, and that related in the Appendix I of my brochure *The Tuberculin Dispensary for the Poor* is an independent and eloquent tribute to the value of tuberculin. If tuberculin can do so much in the hopeless stages, what may it do in an early stage? In no case has any patient suffering from genito-urinary tuberculosis been worse after treatment.

My experience with tuberculin in the diagnosis and treatment of urogenital tuberculosis justifies me in saying that those who have not tried tuberculin in this form of disease cannot form any opinion of its great value. If its value in diagnosis and treatment were fairly appraised and medical measures, including tuberculin

above everything else, were at least tried before surgical methods were adopted, the sufferers from this form of tuberculosis would often be saved from a severe and dangerous surgical operation.—I am, etc.,

London, N.W.1, June 11th. W. CAMAC WILKINSON, M.D.

MENTAL DEFICIENCY ADMINISTRATION.

SIR,—I shall be greatly obliged if you will allow me to comment upon the editorial article in the JOURNAL of June 4th (p. 1020) regarding mental deficiency administration.

I do not propose to refer in detail to the memorandum of the Society of Medical Officers of Health to which you allude. I would merely say that a perusal of this document seems to indicate the existence of so much misunderstanding regarding the report of the Board of Control, its attitude towards the Board is so markedly hostile and its language is so intemperate—indeed, I might not unfairly say so offensive—that one cannot but wonder how such a memorandum came to be passed by the society. This tone is all the more unfortunate since the charge may well be made that those responsible for it do not occupy an entirely disinterested position concerning the chief matter at issue.

With the view that disease of mind should be regarded as part of disease in general I entirely agree. The progress of psychological medicine in the past has suffered greatly from the failure to appreciate this relationship, and one of the most satisfactory features of recent years has been the gradual breaking down of the artificial barrier which has long existed between disease of mind and disease of body. Further, I entirely agree that the administration of the various Acts dealing with mental disease should form part of the public health service, and that there should be the closest co-ordination of all the branches of this service. But you, and the memorandum, go on to say that this co-ordination should be secured by placing the administrative control of all these services in the hands of *one individual*—namely, the medical officer of health—and it is here that I venture to demur. I note your statement that this is the declared policy of the British Medical Association; it would be very interesting to know on what occasions and under what circumstances this decision was arrived at, and particularly to what extent the matter was considered by the general body of the profession, apart from those holding official positions.

My objection to this policy of the creation of the post of Pooh-Bah is based upon the deliberate opinion that, owing to the developments in medicine which have taken place in recent years, it is no longer possible for any single individual to possess that knowledge of all its branches which is necessary for efficient administration. There are certain branches, such, for example, as those dealing with venereal disease, tuberculosis, infectious diseases, inspection and treatment of school children, an adequate knowledge of which is possessed by every well educated medical practitioner. The administration of these services may well remain in the hands of the chief medical officer, the actual work being done by special assistants. But there are other branches of work in which this is not so, and this is peculiarly the case with mental disease. I have no hesitation in saying that the successful ascertainment, diagnosis, treatment, and administrative disposal of persons suffering from disorder, disease, or defect of mind can only be made by a practitioner who has spent years in the study of these conditions; and that there are very few, if any, medical officers of health who possess either the special knowledge, the experience, or even the time to do this work. Here also the work could doubtless be delegated to an assistant possessing the necessary qualifications; but to secure efficiency of administration it would be essential that such subordinate officer should be given a considerable degree of freedom, that his initiative should be encouraged, and, most important, that he should be in personal contact with, and responsible to, the statutory committee charged with this duty. I hold no brief for the Board of Control, but so far as I understand their attitude this is all they ask for. They appear to be of the opinion that part, at all events, of the failure of local authorities to administer the Mental Deficiency Act is due to this work having been relegated to medical officers of health who have little interest in, less special knowledge of, and still less available time to do the work. The failure is unquestionable. The desire of the Board that the work should be in the hands of a specially qualified officer in direct touch with the statutory committee does not seem unreasonable.

For my part I am disposed to think that the time has come when we should go even further. Psychological medicine is not only a highly specialized subject, but it is one which in the near future must inevitably cause more and more duties to be placed upon the shoulders of local administrative authorities. It is a recognized fact that if work is to be well done it must be in the hands of those interested in, and having special knowledge of it, and I very much doubt whether real efficiency will be attained until the administration of this branch of medicine is made a separate department under its own chief. There are plenty of young well qualified members of the profession taking up this special work, but they naturally hesitate to enter the service of local authorities because, as long as they so specialize, they can never attain to more than a subordinate position. This is good neither for progress nor for efficient administration, nor is it in the interests of the profession generally.

It may be suggested that the creation of such a separate department would be to undo the work of co-ordinating the various public health services, and contrary to the aim of the Ministry of Health Act of 1919. I do not think so. The aim of that Act was to secure co-ordination by placing administrative control in the hands of one council and not in the hands of one particular official—that is, the medical officer of health—of that council, and I see no reason why co-ordination should in any way suffer by the heads of the respective departments being colleagues meeting one another on equal terms. Such an arrangement would certainly be more likely to attract practitioners specializing in psychological medicine, and would thereby make for greater efficiency and the advantage of the community.—I am, etc.,

London, W.1, June 6th. A. F. TREDGOLD.

*** Some comment on Dr. Tredgold's letter appears this week at page 1117.

THE MEDICAL MAN IN PARLIAMENT.

SIR,—I was interested to read Dr. Graham Little's assertion in your issue of June 11th (p. 1088) that "the combination of medical and parliamentary work is possible," and "that a man in practice is more able to gauge the feeling of the profession than one who has no further contact with it." The truth or otherwise of these assertions depends upon the conception of the duties of a member of Parliament, either by the member himself or his constituents.

Dr. Little himself is in a privileged position. He is an "Independent" representing London University, and was returned to Parliament to represent the graduates of that University. He lives and practises in London, and as long as his conception of his duties is to look after the interests of that University he can, and does, admirably fulfil those duties. All that is necessary for him is to be in the House when anything affecting the interests of his University is under discussion.

The same ideal can be attained by any man representing a sectional interest, be it doctor, lawyer, business, or railway, etc., and who is content to limit his activities for the use of his section. The same position may be possible for a provincial specialist, but it would not be so easy, as it would necessitate occasional absences from his practice, and I imagine in most cases his practice would suffer.

If, on the other hand, the conception of a member of Parliament's duties is that he is a legislator, legislating for the benefit—or otherwise—of the nation and empire, then I assert most strongly that the duty of a member of Parliament is a "full-time job," and that no man can give his best attention both to Parliament and his profession—one *must* suffer. The fact that probably the majority of the House consists of men in the active practice of their business or profession does not vitiate my contention. They can only come to the House when their

outside activities are over, and vote with very little knowledge of the subject under debate. It may be argued that all votes are given according to party, which is generally true, but it occasionally happens that one has the opportunity in debate of putting a point of view which receives consideration. My main objection to Dr. Little's assertion is the fact that the real work in Parliament is done in standing committee, where each line of a bill is thoroughly discussed and the "back bencher" has his opportunity of directly influencing legislation, and where a man's knowledge and experience are of great value. These committees meet, as a rule, two mornings weekly, from 11 a.m. to 1 p.m., and Dr. Little cannot attend many of these committees without sacrificing part of his professional work. The result is that sometimes there is a difficulty in maintaining a quorum, on account of the outside activities of many of the members, and members who are "free" are compelled to put in full time to make up for the absence of the others.

The statement that men in practice are better able to gauge the feeling of the profession may be true for men in general practice, but I doubt it, particularly in the case of specialists. The activities of the medical press, and letters from medical men in practice, keep the medical member of Parliament who has retired from practice in sufficiently close touch with medical opinion to discount Dr. Little's statement to a large extent.

As most members are returned by the votes of the general public and represent all interests, it follows that the more time the member devotes to his parliamentary duties the better he represents his constituents; and the ideal to be aimed for in my opinion is to regard one's parliamentary duties as a "full-time job."

I do not think it desirable that Parliament should consist of men returned to look after "sectional" interests, although there must be exceptions, as in Dr. Little's case. An increase in the number of medical members would be, I think, an advantage, both to Parliament and the country, as they have been in such intimate touch with people during their professional life that they are eminently suited to understand and voice the opinion and wishes of a very important section of the community—knowledge gained quite apart from the stress and excitement of political controversy, and therefore of more real value. —I am, etc.,

House of Commons, June 13th. A. VERNON DAVIES.

Obituary.

T. H. FIASCHI, M.D.,
Sydney, N.S.W.

THE death occurred on April 17th of Dr. T. H. Fiaschi of Sydney. He was the son of Professor L. Fiaschi of Florence, and was born there in 1853, was educated at the Universities of Pisa and Florence, and, having graduated M.D. and Ch.D., went to New South Wales at the age of 22. He practised first at Cooktown, and was on the Palmer goldfield in its stirring days. Thence he went to Windsor, where he spent some years engaged in the practice of his profession and in agriculture. In 1883 he moved to Sydney.

In 1891 he joined the New South Wales Army Medical Corps as captain, attached to the New South Wales Lancers; in 1896 he was with the Italian Army in Abyssinia, and received the Cavalier's Cross of St. Maurice and Lazarus for his services; and in 1898-1900 he commanded the New South Wales No. 1 Field Hospital with General Hutton's Brigade in South Africa. For services at Paardeberg he was mentioned in dispatches and received the D.S.O., and when he returned to Sydney he was promoted lieutenant-colonel in the A.M.C. He became colonel in 1911, and principal medical officer of the Second Military District of the Commonwealth.

When the great war commenced Dr. Fiaschi went to England as commanding officer of No. 3 Australian General Hospital, which was established eventually at Lemnos. There he worked hard until his health gave way, and he was invalided to England. After a holiday he reported fit for duty, but was not content to accept a position in a military hospital in England, and asked to be allowed to return to Australia. He went first to Italy to visit his native city, and arrived there just after the great Austrian advance in the Trentino. He heard that the Italians urgently needed surgeons, so he resigned from the A.I.F., and joined the Italian army as captain in charge of the surgical department of the hospital at Schio, near the Trentino frontier, and about twelve kilometres from the trenches. There he remained for twelve months.

In 1902 he became honorary surgeon to the Governor-General, and later consulting honorary surgeon to the Sydney Hospital, and examiner in clinical surgery to the University.

Next to his professional work came his passionate love for the soil—for agriculture. He liked nothing better than to be associated with the men of the primary industries, and they esteemed him profoundly too, for, as a viticulturist—he was proprietor of the well known Tizzana vineyards—he helped enormously to develop the wine industry in Australia.

He was one of the foundation members of the New South Wales Branch of the British Medical Association (1901), and was a foundation member of the College of Surgeons of Australasia.

DONALD MACDONALD, M.B., C.M.,
Badenoch, Inverness-shire.

ON May 27th Dr. Donald MacDonald of Craigville, Laggan, died suddenly at Elgin, where he was on holiday. He was the son of the late Mr. Hugh MacDonald of Fort William, who was well known throughout the Western Highlands in the old coaching days as a mail-coach contractor. Dr. MacDonald graduated M.B., C.M. at Edinburgh University in 1893, and after spending some time in general practice in England settled at Laggan and was appointed medical officer of health to Laggan parish council. His genial and kindly disposition made him deservedly popular with his patients and throughout the district of Upper Badenoch. Dr. MacDonald took a close interest in local affairs and acted both as a county councillor and as a member of the education authority. In his sympathies he was essentially a Highlander, being a warm supporter of the old Highland game of shinty, and he travelled long distances to be present at important matches of the game. He had an intimate knowledge of the Gaelic tongue, and conversed in it whenever possible; this rendered firmer the bonds of union between him and his Highland patients. He had for many years been a member of the British Medical Association and frequently attended the meetings of the Inverness Division, travelling about 60 miles to do so. His practice in the wild district of Badenoch was carried on with great difficulty in the winter time, and on one occasion for devotion to duty in perilous circumstances he was awarded the Carnegie Medal. Some two years ago Dr. MacDonald's friends and patients celebrated his semi-jubilee as medical officer of health by publicly presenting him with an illuminated address accompanied by a handsome cheque. His death will be keenly felt throughout the district of Badenoch, where his medical skill and kindly personality had made him greatly beloved.

Dr. WILLIAM ANDERSON FULLER died suddenly on May 27th, in a nursing home at Leeds, at the age of 54. He received his medical education at Guy's Hospital, and obtained the diplomas M.R.C.S., L.R.C.P. in 1898. After holding the post of house-surgeon at the County Hospital, Huntingdon, and the East Sussex Hospital, Hastings, he joined the late Dr. Segrave of Milnthorpe, Westmorland, and after his death carried on the practice for over twenty-one years. He was a vice-president, and later president, of the North Lancashire and South Westmorland Branch of the British Medical Association, and a former chairman of the Kendal Division. He was a magistrate and took an active interest in public life locally. He leaves a widow and three children. A colleague writes: Dr. Fuller represented the best type of country doctor, conscientious,

kindly, and capable, beloved by all his patients. By his death Westmorland loses one of its most valued and respected men.

Dr. JAMES MITCHELL WILSON, who died at his residence in Beverley, Yorkshire, on May 29th, was born in 1844 at Perth, and received his medical education at Glasgow University, where he was one of Lister's dressers; he graduated M.B., C.M. in 1867, and proceeded M.D. in 1883. After holding the post of house-surgeon in the Huntingdon County Hospital, and practising for a time at Chatteris in Cambridgeshire, he decided to devote himself to public health work, and took the D.P.H.Cambridge in 1877. He held appointments successively at Rochdale and Doncaster, and came to the East Riding as county medical officer in 1901. He retired in 1918 and was appointed consulting medical officer of health. He was the author of various books and articles on public health, and contributed a paper on river pollution at the annual meeting of the British Association for the Advancement of Science at Leeds in 1890. Dr. Wilson was a member of the Council of the East York and North Lincoln Branch of the British Medical Association from 1905 to 1909, and a former president of the Branch.

Dr. DONALD SMALLPEICE died in a nursing home on June 2nd at the age of 74. He was a student of Guy's Hospital, and took the diploma of M.R.C.S. in 1883 and that of L.R.C.P. in 1886. He was formerly in practice for some years at Queen Anne's Gate, but owing to a breakdown in health some twenty years ago he left London, and practised for a short time in Rome; he then settled in Felsted, Essex, where he remained until the autumn of last year. During the brief period of his retirement he lived near his earliest home at Guildford. In his youth Dr. Smallpeice had travelled much; he had also read widely, and possessed many interests; so that he was a most entertaining companion with a charming personality. He retained an active interest in medicine to the end of his work as a practitioner, and was greatly beloved by his patients. He leaves a widow, one son, and two daughters.

The following well known foreign medical men have recently died: Professor BARTH, formerly director of the surgical department of the municipal hospital at Danzig; Dr. WILHELM FILEHNE, formerly professor of pharmacology at Breslau, aged 83; Dr. FRANZISKA TIBURTIUS of Berlin, the first German woman doctor, and founder of a clinic for women doctors and a policlinic for indigent women; Dr. A. CAHEN of Hamburg, formerly professor at Strasbourg; and Dr. C. IPSEN, professor of medical jurisprudence at Innsbruck.

Universities and Colleges.

UNIVERSITY OF OXFORD.

IN congregation on June 7th the Vice-Chancellor (Dr. F. W. Pember, Warden of All Souls) moved the promulgation of a decree expressing the thanks of the University to Sir William Dunn's Trustees for a gift of £2 000 to endow a departmental library in the newly-opened Sir William Dunn School of Pathology. The decree was passed by acclamation. An account of the buildings and of the opening ceremony appeared in the BRITISH MEDICAL JOURNAL of March 19th, p. 525.

At a congregation held on June 11th the following medical degrees were conferred:

B.M.—C. P. Blacker, J. C. K. Chilcott.

UNIVERSITY OF CAMBRIDGE.

SIR HUMPHRY ROLLESTON, Bt., Regius Professor of Physic, has been appointed to represent the University at the third Imperial Social Hygiene Congress at Westminster from October 3rd to 7th.

Professor A. V. Hill, Sc.D., F.R.S., Foulerton Research Fellow of the Royal Society, has been elected to an honorary Fellowship at King's College, of which he was a Fellow from 1916 to 1925.

At a congregation held on June 10th the following medical degrees were conferred:

M.B., B.CHIR.—C. H. Hilliard.
B.CHIR.—J. W. E. Cory.

UNIVERSITY OF BRISTOL.

THE following candidates have been approved at the examinations indicated:

FINAL M.B., CH.B. PART I (*including Forensic Medicine and Toxicology*): Phœbe C. Vine; G. D. J. Ball, O. J. P. Bollon, T. L. Cleave, R. D. Jenkins, Helen B. Murgoci, Ethel M. Redman.

PART II (*Completing Examination*): J. C. Batt, H. E. C. Bentley, E. C. Bernard, E. May, E. S. Rogers, J. R. E. Sansom, M. Srisvasti. *Group I* (*Completing Examination*): G. L. Feveley. *Group II* (*Completing Examination*): Helen M. Aldwinckle.

UNIVERSITY OF SHEFFIELD.

THE following appointments were made on June 10th: *Lecturer in Diseases of the Nose and Throat*, W. S. Kerr, M.B., F.R.C.S.; *Research Assistants on Cancer*, A. F. Watson, M.Sc., Ph.D., and Mrs. S. T. Harrison, M.A., Ph.D.

UNIVERSITY OF GLASGOW.

MACEWEN MEMORIAL LECTURE.

IT will be remembered that after the death of Sir William Macewen, Professor of Surgery in the University of Glasgow from 1892 to 1924, a committee was formed to promote a fund for the purpose of commemorating his life and work. The first purpose of the fund was to procure a bust for presentation to the University and a replica to Lady Macewen. The second purpose was the establishment of a Macewen Memorial Lecture, and the third the foundation of a Macewen Medal in the Class of Surgery.

The busts have been presented to the University and to Lady Macewen and the medal has been founded and the first award made. The first Memorial Lecture is to be delivered by Professor Harvey Cushing, C.B., M.D., LL.D., Harvard University, U.S.A., in the Zoological Lecture Theatre of the University on Tuesday next, June 21st, at 3 p.m. The lecture is open to past and present students of medicine and to others interested. Subscribers to the Foundation Fund are specially invited.

UNIVERSITY OF DUBLIN.

TRINITY COLLEGE.

Bicentenary Memorial Fund, School of Physic.

THE fund subscribed by the medical graduates of Dublin University to commemorate the bicentenary of the foundation of the School of Physic has now been handed to the Board of Trinity College, for the purpose of establishing a Bicentenary Memorial Prize to be awarded each year to the winner of the Medical or Surgical Travelling Prize. In accepting the fund the Board expresses thanks to the subscribers for "a very generous benefaction to the College." The amount of the fund is about £730.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

AN ordinary Council meeting was held on June 9th, when the President, Sir Berkeley Moynihan, Bt., was in the chair.

Fellowship.

It was reported that 108 candidates had presented themselves for the Fellowship examination, of whom 25 were successful, including H. I. Deitch, who had not yet attained the requisite age. The diploma of Fellowship was conferred upon the following candidates:

H. B. Bul'en, E. Wolff, W. A. Richards, E. L. Robert, C. M. Gwillim, R. V. Hudson, J. D. R. Murray, J. Roberts, A. L. Walker, W. A. Mill, W. H. Gervis, G. H. Pitt, F. W. Roques, M. A. Paul, W. H. A. Dodd, E. W. Riches, H. G. Armstrong, Alfreda H. Baker, W. K. Connell, R. L. Dodds, I. J. Fraser, W. J. Henry, D. McKelvey, S. V. Unsworth.

Membership.

The diploma of M.R.C.S. was conferred upon the following candidates who have passed the requisite examinations and complied with the by-laws:

V. F. Anderson, F. A. J. Bouloux, Ethel E. M. Ogilvie, Dulcie J. Peake, Winifred M. Turner, Joan B. Walker.

Appointment of Representatives.

Sir John Bland-Sutton was appointed to represent the College at the commemoration in October next of the centenary of the granting of the Charter of King's College, Toronto, now the University of Toronto.

Sir Berkeley Moynihan was re-elected to represent the College on the Court of Governors of the University of Sheffield for three years.

Votes of Thanks.

The thanks of the Council were expressed to Sir John Bland-Sutton, on his retirement from the Council, for his services during his term of office on the Council, extending over seventeen years, including three years as President.

A vote of thanks was given to Miss Hunter of Blackheath for presenting to the College a combined bookcase and writing table, formerly the property of John Hunter.

Examiners.

The following examiners were appointed for the ensuing year:

Dental Surgery (Surgical Section): L. B. Rawling, H. S. Clogg, T. P. Legg, G. S. Simpson, R. J. Howard, G. E. O. Williams, C. H. S. Frankau, and J. Murray. *Anatomy for the Fellowship*: W. Wright, F. G. Parsons, W. E. Le Gros Clark, and C. P. Wakeley (re-elected). *Physiology for the Fellowship*: J. B. Leathes and H. E. Roaf (re-elected), C. A. Lovatt Evans and R. J. S. Macdowall.

Under the Conjoint Examining Board for the ensuing year:

Elementary Biology: T. W. Shore and J. P. Hill. *Anatomy:* H. A. Harris, O. S. Hühnan, and J. B. Hume (re-elected). *Physiology:* G. A. Buckmaster (re-elected) and D. H. de Souza. *Midwifery:* D. W. Roy, H. B. Whitehouse, and C. White (re-elected). T. B. Davies. *Diploma in Public Health:* Part I, R. T. Hewlett (re-elected); Part II, C. W. Hutt. *Diploma in Tropical Medicine and Hygiene:* Pathology and Tropical Hygiene, W. P. MacArthur (re-elected); Tropical Medicine and Surgery, P. H. Manson-Bahr (re-elected). *Diploma in Ophthalmic Medicine and Surgery:* Part I, C. B. Goulden and H. W. Lyle (re-elected); Part II, R. A. Greeves. *Diploma in Psychological Medicine:* F. L. Golla (re-elected). *Laryngology and Otology:* Part I, A. H. Cheatle (re-elected) and W. M. Mollison; Part II, S. R. Scott (re-elected).

ROYAL COLLEGE OF PHYSICIANS OF IRELAND.

AT the monthly business meeting of the Fellows, held on June 10th, the President duly admitted as members of the College the following successful candidates: Samuel Barron, L.R.C.P. and S.I., Timothy Maurice Healy, M.B., N.U.I. Mr. Healy is a son of H.E. the Governor-General of the Irish Free State, and served for some years as Assistant Master of the Combe Lying-in Hospital, Dublin.

ROYAL COLLEGE OF SURGEONS IN IRELAND.

THE following officers have been re-elected for the ensuing year: *President:* Andrew Fullerton, F.R.C.S.I.; *Vice-President,* Thomas E. Gordon, F.R.C.S.I.; *Secretary,* Sir F. Conway Dwyer, F.R.C.S.I.

ROCKEFELLER MEDICAL FELLOWSHIPS.

THE Medical Research Council announces that on behalf of the Rockefeller Foundation it has made the following awards of Medical Fellowships provided by the Foundation and tenable in the United States of America during the academic year 1927-28. These Fellowships are awarded to graduates who have had some training in research work either in the primary sciences of medicine or in clinical medicine or surgery, and who are likely to profit by a period of work at a university or other chosen centre in America before taking up positions for higher teaching or research in the British Isles:

ROBERT WILLIAM FITZGERALD COLLIS, M.B.Cantab., M.R.C.P.; Resident Medical Officer, King's College Hospital, London.
DAVID KRESTIN, M.D.Lond., M.R.C.P.; Medical Registrar, London Hospital.
GEOFFREY LEWIS PESKETT, M.A.Oxon.; Demonstrator in Biochemistry, University of Oxford.
Miss ISABELLA MCDOUGALL ROBERTSON, M.D.Lond.; Research Worker in the Pathology Laboratory, Maudsley Hospital, London.
THOMAS TENNENT, M.B.Glas.; Assistant Medical Officer, Maudsley Hospital, London.
EDGAR WILLIAM TODD, M.D Cantab.; Research Worker in the Inoculation Department, St. Mary's Hospital, London.

Dr. Tennent has been appointed on modified conditions while holding a scholarship from another source.

Medical Notes in Parliament.

[FROM OUR PARLIAMENTARY CORRESPONDENT.]

THE House of Commons, which reassembled on June 13th, has completed the Committee stage of the Trade Disputes and Trade Unions Bill. Other business for the week included the second reading of the Local Authorities (Audit) Bill, which proposes that members of local authorities against whom surcharges of more than £500 are made shall be disqualified for five years.

The Government Whips have decided to oppose the passage of the Dogs' (Protection) Bill in the House of Commons. Several medical members have given notices of opposition to it.

Removal of Prisoners for Treatment.

Mental Deficiency.—In the ten years from 1916-17 to 1925-26, prisoners in England and Wales were removed to mental institutions as follows. Under Section 9 of the Mental Deficiency Act, 1913: In 1916-17, 29; 1917-18, 38; 1918-19, 63; 1919-20, 102; 1920-21, 91; 1921-22, 57; 1922-23, 66; 1923-24, 57; 1924-25, 24; and 1925-26, 43. Under Section 2 of the Criminal Lunatics Act, 1884, the transferences were as follows: 1916-17, 125; 1917-18, 101; 1918-19, 97; 1919-20, 89; 1920-21, 112; 1921-22, 102; 1922-23, 134; 1923-24, 104; 1924-25, 114; and 1925-26, 106. Persons dealt with under Section 8 of the Mental Deficiency Act, 1913, criminal lunatics ordered by a court to be detained during His Majesty's pleasure, and persons received into mental institutions on discharge from prison on expiry of sentence are not included in these statistics.

Surgical or Medical Treatment.—The number of prisoners removed, under Section 17 (6) of the Criminal Justice Administration Act, 1914, for surgical or medical treatment which could not be given in prison in each of the ten years from 1916-17 to 1925-26, were 20, 26, 22, 72, 54, 86, 66, 57, 82, and 95.

Grants to Voluntary Hospitals.—On June 13th Sir Kingsley Wood, replying to Mr. Lunn, said that, excluding contributions towards specific grant-aided services, the total Exchequer grants in aid of the general expenses of voluntary hospitals since 1918 had amounted to £500,000, voted by Parliament on the recommendation of Lord Cave's Committee. The Voluntary Hospitals Commission was still in existence, but it had no funds at its disposal.

Medical News.

DR. FRANK WACHER, who for fifty years has been medical officer of health for Canterbury, was on May 31st made an honorary freeman of that city. He was chairman of the Canterbury Division of the British Medical Association in 1912, and has served as vice-president of the South-Eastern Branch.

THE annual dinner of the Harveian Society of London was held at the Connaught Rooms on Thursday, June 9th, when the president, Dr. E. Le Févre Payne, was in the chair. The Lord Mayor of London was among the guests, and on leaving to keep another engagement made a graceful speech deputing Sir Berkeley Moynihan to reply for him on behalf of the visitors. The toast "The Harveian Society" was proposed by Sir John Rose Bradford. The president, in replying, pointed out that this year the connexion of the Society with Harvey was closer than usual, inasmuch as he believed that he was the first president who had been educated at Harvey's old school, King's School, Canterbury. The health of the many distinguished guests, proposed by Dr. Graham Little, M.P., was acknowledged by Mr. A. Latter, head master of King's School, Canterbury, Sir Berkeley Moynihan, and Mr. F. Freke Palmer. About 110 members and guests were present at the dinner.

A COURSE in advanced bacteriology will commence at the London School of Hygiene and Tropical Medicine on October 4th. It will be under the direction of Professor Topley and is intended for a limited number of post-graduate students who desire to fit themselves for bacteriological appointments at home or abroad. The fee for the course, which will be continued throughout the academic year, is 42 guineas. Further particulars can be obtained on application to the Secretary of the School, Malet Street, London, W.C.1.

THE Fellowship of Medicine and Post-Graduate Medical Association announces that Dr. A. J. Whiting will give a medical clinical demonstration at the Prince of Wales's Hospital on June 20th at 2.30 p.m.; Mr. C. A. Joll, a demonstration on surgical treatment of goitre, at the Royal Free Hospital on June 22nd at 4; Mr. Griffith, a clinical ophthalmic demonstration at the Royal Eye Hospital on June 24th at 3. All these demonstrations are free to members of the medical profession. On June 27th a special fortnight's course in chest diseases will begin at the City of London Hospital for Diseases of the Heart and Lungs (fee £2 2s.). In July five special courses will be given in various subjects. The first will be an all-day two-weeks' course in cardiology, from July 4th to 16th, at the National Hospital for Diseases of the Heart; numbers strictly limited to twenty. On July 11th the Prince of Wales's Hospital Group will start a fortnight's course in general medicine, surgery, and the specialties. On the same date there will begin a week's course at the St. Mark's Hospital for Diseases of the Rectum. The other two courses taking place in July are part-time courses only; one in neurology at the West End Hospital for Nervous Diseases, starting on the 4th and lasting for a month; the other in infectious fevers at the Park Hospital, on Wednesdays and Saturdays, from July 13th to 30th. Copies of all syllabuses are obtainable from the Fellowship of Medicine at 1, Wimpole Street. A general course of work is also provided at the associated hospitals; for this a comprehensive ticket and a separate programme are issued.

THE centenary of the birth of Lord Lister and his connexion with King's College will be celebrated by the King's College Medical Society on Thursday next, June 23rd. A wreath will be placed on the memorial tablet outside the chapel by the president of the Medical Society at 4.50 p.m., and at 5 p.m. Sir Arthur Keith will take the chair for a lecture by Sir StClair Thomson, Emeritus Professor of Laryngology in the college, who will speak of Lister's personality and his achievements. Medical students and others interested in medicine are invited to be present.

A NATIONAL Conference on Maternity and Infant Welfare, under the auspices of the Central Council for Infant and Child Welfare, will be held in the Great Hall of the British Medical Association House, Tavistock Square, W.C.1, under the presidency of the Minister of Health, from July 5th to 8th inclusive. At the opening session Mr. Neville Chamberlain will deliver an address, which will be followed by a discussion on wet nursing. Other subjects selected for debate include the problem of the expectant unmarried mother; the practical teaching of mothercraft; the provision of efficient sick nursing in the homes of children under school age; day nursery problems; the incidence of venereal diseases in ante-natal and post-natal clinics; the results of artificial light treatment for children under school age; and respiratory disease in relation to infantile mortality. A lecture on the pasteurization of milk in relation to surgical tuberculosis, by

Dr. A. Stanley Griffiths, will be delivered on July 5th at 7.30 p.m. A dinner for members of the medical profession attending the conference has been arranged at the Florence Restaurant on July 5th, after which an informal discussion on immunization against diphtheria will be opened by Dr. W. Ashley Lethem and Dr. J. Graham Forbes. Friday, July 8th, will be devoted to visits to centres and institutions in and around London.

THE annual general meeting of the Research Defence Society will be held at the house of the Medical Society of London, 11, Chandos Street, W.1, on Tuesday, June 21st; Lord Lamington will take the chair at 3 p.m. The first Stephen Paget Memorial Lecture will be delivered by Professor Julian S. Huxley, M.A., who has chosen as his subject "Research and the community."

THE annual summer dinner of the Glasgow University Club, London, will be held at the Trocadero Restaurant, Piccadilly, W.1, on Friday, July 1st, at 7.15 for 7.30 p.m. precisely. Dr. C. O. Hawthorne will preside. Any Glasgow University men who, though not members of the club, desire to be present are requested to communicate with the honorary secretaries, 62, Harley House, N.W.1.

A MEETING of the Society for the Study of Inebriety will be held in the rooms of the Medical Society of London, 11, Chandos Street, Cavendish Square, on July 12th, at 4 p.m., when Sir Arthur Newsholme will deliver a presidential address on the aims and work of the society, and Dr. Godfrey Carter, lecturer on forensic medicine in Sheffield University, will open a discussion on the detection of drunkenness, with especial reference to the concentration of alcohol in the blood and urine.

THE annual meeting of the Incorporated Lancashire and Cheshire Society for the Permanent Care of the Feeble-Minded will be held in the Recreation Room of the Sandlebridge Institution, Alderley Edge, on Tuesday, June 21st, at 3.30 p.m. Sir Frederick J. Willis, chairman of the Board of Control, will preside and open the Noah's Ark Home. The school and the homes will be open for inspection from 3 p.m. and tea will be served at Warford Hall at 4.30 p.m.

COMMEMORATION day at Livingstone College was celebrated on June 10th, when the President of the Royal College of Physicians, Sir John Rose Bradford, was in the chair. He commended the work of the college, and expressed the opinion that in this case "a little knowledge" was not "a dangerous thing," but capable of being of great service to humanity, especially to missionaries scattered all over the world, where it was impossible for the inhabitants to receive adequate medical treatment. He had been much impressed by reports he had read from students in all parts of the world, who were doing valuable work for the prevention as well as the treatment of disease. The Rev. C. Redman, a missionary of the Society for the Propagation of the Gospel, and an old student of the college, said that he had found what he had learnt there of great use when working in a district in Madagascar, where often the services of a doctor could not be obtained. Later on, when put in charge of a theological college, he had made the teaching of the prevention and treatment of disease part of the curriculum, so that students went out into the villages possessing knowledge very useful in dealing with the great ignorance of the people. Other speeches were made, including one by the Dowager Lady Buxton, who, during a recent visit to Abyssinia, had admired the work of an old student of the college.

THE Association of Physicians held its annual meeting in Belfast on June 3rd and 4th. Professor J. A. Lindsay was president, and Professor W. W. D. Thomson acted as local honorary secretary; with the aid of the physicians attached to the hospitals the local members formed themselves into a committee to provide clinical demonstrations suitable for the occasion, and to give a hearty welcome to the visitors. According to the usual routine sittings were held morning and afternoon for discussion, the morning in the University, and the afternoon in the King Edward Memorial Hall of the Royal Victoria Hospital, where on both days, in the interval, a large amount of clinical material had been collected in the out-patient department, and demonstrations were given of neurological and pathological interest. In addition a collection of items of local interest, old local books, and portraits had been formed. An excellent pamphlet of all these demonstrations, due to the labours of one or two members of the local committee, much facilitated their study.

THE second international post-graduate course in diseases of the heart and gynaecology, which was held at Franzensbad from May 22nd to 26th, was attended by six hundred medical practitioners from Czecho-Slovakia, Germany, Austria, Hungary, Poland, Rumania, Jugo-Slavia, Russia, Denmark, and Holland. The communications included addresses on cholelithiasis and pregnancy by Professor Frigyesi of Budapest, and on the various forms of circulatory obstruction by Professor Wenkebach, Vienna.

LORD EUSTACE PERCY, M.P., President of the Board of Education, will distribute the prizes at the London Hospital Medical College and Dental School on Wednesday, June 29th, at 3 p.m., in the College Library. Academic dress will be worn.

THE new ward and enlarged accommodation for out-patients at the Southend Victoria Hospital was opened on May 25th. The number of beds at this hospital, which is now eighty-six, has been doubled during the past five years, and £20,000 has been spent on extension and equipment.

A STAINED glass window has been erected in St. Michael's Parish Church, Highgate, in memory of the late Dr. Frederick William Crowdy, who for thirty-two years was a warden of the church. The dedication service was conducted by the Bishop of Willesden.

THE late Mr. F. A. Southam, emeritus professor of surgery in the University of Manchester, who died on March 9th, has left estate of the gross value of £44,900.

THE seventh congress entitled Les Journées Médicales de Bruxelles will be held from June 25th to 29th at Brussels. Excursions to Tournai and other interesting places will be arranged in connexion with it, and there will be an international exhibition of art and science applied to medicine and surgery. Further information may be obtained from the secretary, Dr. R. Beckers, 62, rue Froissart, Brussels.

THE thirty-first congress of French neurologists will be held at Blois from July 25th to 30th. Detailed information may be obtained from the secretary, Dr. M. Olivier, Blois.

ACCORDING to the *Journal of the American Medical Association* the total deaths from diphtheria in the seventy-eight cities of the United States with more than 100,000 inhabitants were approximately 3,000 in a population of 31,000,000, or more than three times the typhoid mortality in the same cities. The total average typhoid death rate for fifty-nine large cities in the United States last year was 2.77 per 100,000, the lowest ever reported in that country.

DR. PAUL CARNOT, director of *Paris Médical*, has been nominated professor of clinical medicine in the Paris faculty of medicine in succession to the late Professor Gilbert.

PROFESSOR FÜLLEBORN of the Hamburg Institute for Tropical Diseases has been invited by the Argentine Government to visit South America to study hookworm disease.

Letters, Notes, and Answers.

All communications in regard to editorial business should be addressed to ***The EDITOR, British Medical Journal, British Medical Association House, Tavistock Square, W.C.1.***

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the BRITISH MEDICAL JOURNAL alone unless the contrary be stated. Correspondents who wish notice to be taken of their communications should authenticate them with their *names, not necessarily for publication.*

Authors desiring REPRINTS of their articles published in the BRITISH MEDICAL JOURNAL must communicate with the Financial Secretary and Business Manager, British Medical Association House, Tavistock Square, W.C.1, on receipt of proofs.

All communications with reference to ADVERTISEMENTS, as well as orders for copies of the JOURNAL, should be addressed to the Financial Secretary and Business Manager.

The ***TELEPHONE NUMBERS*** of the British Medical Association and the BRITISH MEDICAL JOURNAL are *MUSEUM 9861, 9862, 9863,* and *9864* (internal exchange, four lines).

The ***TELEGRAPHIC ADDRESSES*** are:

EDITOR of the BRITISH MEDICAL JOURNAL, *Aitiology Westcent, London.*

FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements, etc.), *Articulate Westcent, London.*

MEDICAL SECRETARY, *Medisecra Westcent, London.*

The address of the Irish Office of the British Medical Association is 16, South Frederick Street, Dublin (telegrams: *Bacillus, Dublin*; telephone: 4737 Dublin), and of the Scottish Office, 6, Drumsheugh Gardens, Edinburgh (telegrams: *Associate, Edinburgh*; telephone: 4361 Central).

QUERIES AND ANSWERS.

MULTIPLE BIRTHS.

DR. L. WALLACE (127, Gloucester Terrace, Hyde Park, W.2) asks for references to statistics, or opinions, concerning the occurrence of multiple births in the different "social strata" of the community.

POISONING BY EUCALYPTUS OIL.

DR. VERNON NEWTON (Pontycymmer, Glam.) writes: Dr. P. Gibbin, in describing a case of eucalyptus poisoning in the JOURNAL of June 4th (p. 1005), states that he has failed "to find

any record in any textbook" of toxic symptoms produced by the drug. May I, therefore, draw attention to Professor Glaister's *Medical Jurisprudence and Toxicology* (fourth edition, p. 821)? There two cases (one fatal) of poisoning by eucalyptus oil are described in full. The early signs and symptoms in these cases appear to have been similar to those in Dr. Gibbin's—except that in each case the pulse is fast. Glaister also mentions two cases of this poisoning seen by Kirkness.

INCOME TAX.

Expense Attached to Appointment.

A FULL-TIME lecturer in anatomy states that one of the terms of his appointment was that he was "expected to engage in higher study and research." He has claimed to deduct the expense of visiting meetings of the Anatomical Society to exhibit his results; those expenses have been disregarded, as also the expense entailed in applying for better appointments.

*** We agree that the terms used imply as a binding legal condition that the research work shall be done, and that the expense of attending the meetings is allowable if that is similarly enjoined, either expressly or by implication. The cost of applying for another appointment is not legally deductible.

Foreign Residence.

'W. F." is about to leave for Egypt with his wife on a five years' agreement; he proposes to retain his own house in Scotland, leaving his furniture therein, and to return to Scotland annually for a six weeks' vacation. He has been advised that he will be liable only in respect of remittances to him in this country.

*** We think "W. F." runs a risk of being held to be liable on his whole income. This is due to the fact that he will be retaining a residence in the United Kingdom to which he can, and possibly will, return at yearly intervals. In such circumstances he might be held to be "resident" and "ordinarily resident" in Scotland, and, if so, would be liable on the whole of his earnings, War Loan interest, etc. We are strongly of opinion that, from the point of view of taxation, he would be well advised to let his house for three or five years, and get rid of such furniture as he might not wish to store for so long. In such circumstances he might not be held to be resident here, even when he returns on vacation, and so escape income tax altogether. A ruling might be obtainable from the Secretary, Inland Revenue, Somerset House, W.C.2, if a full statement of the facts is sent with a request for an opinion.

Motor Car Depreciation.

"W. A. W." replaced his car in 1924 and was allowed the net cost. What will be the position with regard to income tax if he replaces his present car this year?

*** The 1924 replacement would reduce the 1924 earnings, and, owing to the operation of the three years' average, would affect (in the normal course) the assessments for 1925–26, 1926–27, and 1927–28. In fact, it has no doubt affected the two former years, but owing to the statutory change in the basis of assessment the 1927–28 assessment will be made at the amount of the 1926 earnings, and consequently will be unaffected by the 1924 replacement. If a further replacement occurs now it will have its full effect on the 1928–29 assessment, because it will be fixed by the amount of the net earnings of 1927.

"W. M." purchased his present car in 1922 for £550 and has received an offer of £80 for it; the present cost of a similar car is £470.

*** If he puts the transactions through this year he can treat as an expense £470–£80=£390, the amount of the out-of-pocket cost of renewal. This will reduce the amount of his net professional earnings for 1927, and that amount will form the basis of his liability to tax for 1928–29.

"E. M. A." refers to an answer in an earlier issue, and states that he has always claimed to deduct the running cost of his car, but has never claimed for depreciation.

*** In such circumstances the amount of the net expenditure incurred on renewing the car—exclusive of any cost of improvement—can be claimed as a professional expense of the year when the present car is replaced.

LETTERS, NOTES, ETC.

NEURITIS AND ULTRA-VIOLET RAYS.

DR. PERCY HALL (London, W.1) writes in reply to Dr. C. Burgoyne Pasley, whose inquiry appeared on June 11th (p. 1087): Experience has shown me that the great majority of cases of neuritis can be distinctly benefited, and often cured, by a course of ultra-violet rays. Certain types of case, however, where there is distinct evidence of toxaemia or chronic septic infections, leave the patient in a condition which "sensitizes" him in a peculiar manner to the action of the rays. Such would appear to have been the case in the patient in question. Symptoms occasionally arise resembling the mild forms of anaphylaxis. Having had several instances of this, I have found that continuing the use of ultra-violet rays in small doses has led to desensitization and cure. Dr. Pasley does not state the type of lamp he used, its age and output, the exposure times, distance and intervals between doses, or total number of doses. What would be regarded as moderate doses in average individuals would—in such a case as he describes—be excessive.

MIGRAINE AND HYPNOTICS.

DR. F. G. BUSHNELL (Plymouth) writes: I have had under close observation within the last six months a case of headache of migraine type in a man, aged 59, leading a professional life; the attacks during the last six months were of a disabling nature, though he had suffered from them off and on for twenty or thirty years. There was a history of insomnia in childhood and some proneness to mental worry, and lately of anxiety and excitement, consequent on public duties. There was a family history of sick headaches and of a seemingly mild attack of poliomyelitis in childhood, confined to the muscles of the right leg and foot. A sister died suddenly at 57 years of age from arterio-sclerosis. Affections of the eyes, ears and antrum, and nasal sinuses, of disordered metabolism, of intestinal toxaemia, of arterio-sclerosis or high blood pressure, of renal disease, and of cerebral tumour were eliminated from the diagnosis. Clinical features were the occurrence of ache in the forehead and back of the eyes, commencing on waking in the morning after disordered sleep, gradually getting worse during the day, and accompanied by a flushing of the face and free passage of pale watery urine. They ended suddenly during sleep, sometimes of a few minutes during the day or during the night. Eventually they were of daily occurrence and he was ordered rest abroad. This and bromide mixtures failed materially to relieve the attacks, and a [illegible] by Dr. C. Bolton. Since [illegible] able to carry on his work [illegible], then, that the ultimate cause of migraine lies in its association with the disordered function of sleep; its treatment by hypnotics and removal of the exciting causes are necessary as accessories to recovery. . . . The physiology and pathology of sleep are unknown (see *Recent* [illegible] According to Pavlov, sleep and inhibi- [illegible] process, and he associates inhibition [illegible] auses of migraine are unsolved, but research workers might help us to determine the relationship of migraine to disorder of sleep and to cortical inhibition.

HERPES AND VARICELLA.

DR. R. LYNN HEARD (Bexley, Kent) writes: I am not surprised that Dr. Gallaugher (BRITISH MEDICAL JOURNAL, June 11th, p. 1088) should not be able to trace a connexion between a specific case of herpes and an antecedent case of varicella. These cases do occur, but much more rarely than varicella contracted from herpes. This has been vouched for now by a number of different observers, and its possibility should be beyond dispute; but most instances of herpes, I am inclined to think, are derived by infection, not from varicella (which may happen), but much more usually from another herpetic patient. The fact that while herpes is infectious, so many people have had varicella in early life, becoming thereby immune, explains why a number of cases of herpes crop up more or less simultaneously and yet that we do not find two in the one house at the same time.

MOTOR REPAIRS.

MESSRS. MANN, EGERTON AND CO., consulting engineers to the Medical Insurance Agency, have recently removed their service works from Kilburn to Church Street, Edgware Road, N.W.8. The new premises are much larger than the old, and more accessible, being only five minutes from the Marble Arch. They provide accommodation for 200 cars, and are being fitted with all the necessary machinery for mechanical and coachwork repairs, equipment for cellulose painting, and arrangements for washing and garaging cars, inflating tyres, and testing and repairing batteries, and electrical mechanism. It is intended that the stores department shall include spare parts for all the best known makes of car. The company maintains a fleet of loan cars, which are let out to medical men at 10s. a day, with an extra charge for mileage exceeding thirty miles a day, during the time their own cars are under repair at the company's works. The extent and equipment of Messrs. Mann, Egerton's new premises are a guarantee of ever-increasing efficiency in their service to medical motorists.

ERRATUM.

WE regret that, owing to a printer's error, the word "exophthalmos" was substituted for "enophthalmos" in the interesting note by Dr. M. C. Torrance on paralysis of the cervical sympathetic complicating mumps, published in last week's issue of the JOURNAL at page 1088.

VACANCIES.

NOTIFICATIONS of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals, will be found at pages 47, 48, 49, 52, and 53 of our advertisement columns, and advertisements as to partnerships, assistantships, and locumtenencies at pages 50 and 51.

A short summary of vacant posts notified in the advertisement columns appears in the *Supplement* at page 247.

Some Experiences IN BRONCHOSCOPY AND OESOPHAGOSCOPY.

BY

HERBERT TILLEY, F.R.C.S.,

SURGEON, EAR AND THROAT DEPARTMENT, UNIVERSITY COLLEGE HOSPITAL.

(*With Special Plate.*)

THERE can be few accidents productive of more acute mental anxiety and physical distress than those caused when the entry of a foreign body into the lower air passages brings about an immediate difficulty in breathing. On rare occasions, but with less suddenness, a pathological lesion will effect the same results, and I will later describe a case in point. Similarly, lesser degrees of alarm and discomfort may follow the impaction of a foreign body in the oesophagus if it should happen to prevent or render difficult the natural and unhindered passage of food into the stomach.

It was as a method for the safe and successful treatment of such accidents that direct endoscopy first established itself and still remains without a rival, but its range of usefulness has been extended to the diagnosis and treatment of such pathological conditions in the lower air passages and the oesophagus as can be directly inspected by the surgeon. For such advances we are mainly indebted to the brilliant work of Chevalier Jackson (Philadelphia), and those interested in the subject will do well to read the report of his address given at the meeting of the British Medical Association at Bath in 1925.[1]

It will be my purpose in this communication to mention some of the more serious symptoms consequent upon the entry of a foreign body into the lower air passages or the oesophagus, and to emphasize how they may be avoided or minimized by the general practitioner who is usually the first to whom the patient applies. It may be more convenient to give the histories of six illustrative cases first of all and then to see what lessons may be learnt from them.

CASE I.—*A portion of rabbit bone lodged in a lower lobe of the right bronchus for sixteen months; Removal by peroral bronchoscopy: Recovery.*

I am indebted to Dr. Eric Gardner (Weybridge) for the following history of his patient's symptoms. "A married woman, aged 56, consulted me in the evening of October 11th, 1925. She thought she had asthma, although she had never had it before. For certain reasons the consultation was a hurried one, but I had time to notice that any slight exertion caused a definite inspiratory stridor, and that the movement of the right side of the chest was defective. I made no diagnosis, and arranged for a further and more detailed examination, because I suspected the possibility of a foreign body. At her second visit the following history was obtained. About three weeks previously she choked during dinner time, and a medical man living next door was sent for. He passed his finger down her throat and the spasm stopped. The next day any quick movement caused cough, and this became worse and was particularly noticeable when motoring against the wind. Meantime, difficulty in breathing increased and was accompanied by stridor. My examination revealed deficient air entry into the base of the right lung, and a small area below the angle of the right scapula where occasionally a few râles could be heard.

"A radiograph of the chest was taken by Mr. Charles Roberts (Woking), and showed a very indefinite linear shadow low down in the base of the right lung. On October 25th bronchoscopy was performed with a negative result.

"A few days later the patient was operated on for anal fistula and haemorrhoids and did not get out till the second week in December. In the meanwhile her cough had gone.

"She caught a severe cold, and, on December 31st, had one of the most terrible coughs I have ever heard. It failed to respond to any treatment, was incessant day and night, and was accompanied by expectoration. The evening temperature for four days was 104°. Physical signs were very indefinite; there were a few scattered râles in both bases, but more marked in the right.

"Improvement was slow except that the cough remained, and the patient went to the South of France in February, 1926. There the symptoms were very troublesome, but improved slightly during March and April, although talking, moving quickly, and cold air always brought it on, and it persisted during the summer. In September the patient went to Scotland, caught cold, the cough became very severe, and she expectorated a quantity of pus, which gave a certain amount of relief to the symptoms. She now noticed that the cough was always aggravated if she lay on her right side.

"On November 13th a second radiograph was taken and gave a clearer definition of the linear shadow seen in the first screening. An attack of influenza precluded another bronchoscopic examination while it aggravated the cough, which was very incessant day and night. The physical signs in the right base became very definite, and over a small area the breath sounds were loud and harsh. These conditions improved very slowly, and on January 18th she saw you."

Bronchoscopy.

On January 24th the patient was anaesthetized by Mr. Raymond Apperley, and on passing a small bronchoscope into the right lower lobe bronchus it was seen to be very congested when compared with the upper and middle lobe bronchi (Fig. 4). Some minutes were spent in removing the secretion and checking its formation by the application of a mixture of adrenaline and cocaine. Then a small bead of pus appeared in the mouth of a small bronchus, and on inserting the closed ends of Jackson's "mosquito," side-grasping, bronchoscopy forceps a grating sensation was felt. The foreign body was then grasped and removed, and proved to be a thin T-shaped piece of flattened bone 2 cm. in its long and 1 cm. in its shorter limb, and one end of the latter terminated in a sharp point.

A week after the operation the patient said, "I can talk and run upstairs. I can go out into cold air, and I can lie on my right side, and nothing makes me cough at all."

(It has been found impossible to reproduce for illustration the ill defined shadow of the foreign body as seen in the negative and *radiograph.*)

CASE II.—*A paper-fastener lodged for twenty-one months in the left lower lobe bronchus of a boy aged 7 years: Removal by peroral bronchoscopy: Recovery.* (Fig. 1.)

This case was reported in the BRITISH MEDICAL JOURNAL of November 18th, 1922 (p. 973), and readers interested in the subject are referred for details to that source. It will suffice to say that the chief symptoms were a chronic cough, the child "was always bronchial and short of breath, and the noise he made at night was like air passing through a small hole." In addition, there were frequent attacks of pyrexia after exertion, and examination of the chest by Dr. Batty Shaw showed definite physical signs of deficient air entry into the left lower lobe. Dr. Salmond's radiograph clearly showed the paper-fastener in the left bronchus, with the extended wings directed upwards.

On June 29th, 1922, I removed it by peroral bronchoscopy. The patient left the nursing home two days later and has remained well since. The operation was very difficult owing to the bleeding caused by oedematous granulations which surrounded and obscured the foreign body.

CASE III.—*Spicule of chicken bone removed from the oesophagus of a man four days after it had been swallowed: Cellulitis in the neck: Oesophagoscopy: Recovery.*

A man, aged 50, felt a sharp pain in his throat when eating some chicken. Shortly after dinner he experienced discomfort in the left side of his neck about the level of the collar bone, and at each succeeding meal difficulty and pain in swallowing increased. On the third day he could not swallow liquids. When I saw the patient he looked ill and distressed; temperature 100.6°. There was a diffuse and tender swelling over and in the neighbourhood of the lower half of the left sterno-mastoid.

He went at once into a nursing home, and four hours later and by direct oesophagoscopy I detected the bone about three to four inches below the entrance of the gullet. One end of the bone transfixed the mucous membrane, and on dislodging it about 3 drachms of intensely fetid pus escaped. A rubber feeding tube was passed through the gullet and a feed of egg, milk, and brandy was administered. The patient left the home in three days, and quickly recovered his normal health.

CASE IV.—*A splinter of rabbit bone impacted in the oesophagus for five days: Cervical cellulitis: Oesophagoscopy: Recovery.*

A man, aged 35, consulted me in 1924 because of increasing difficulty and severe pain on swallowing. The symptoms were ascribed to scratching the throat when he "was eating some of the stump of a broccoli."

I had known the patient as a typical English athlete, a playing member of one of the leading county cricket clubs and of a prominent Association football club. I mention these facts because of the dramatic change in his usual appearance since the above accident occurred. He was very weak, the complexion pale and sallow, and the eyes sunken; temperature 101.2°, pulse 110. The left side of the neck was diffusely swollen and very tender on pressure. I sent him to Dr. Salmond, who reported to me within an hour that the *x*-ray screen revealed a foreign body in the gullet about the level of the manubrium sterni.

The patient immediately went in a nursing home, and a few hours later I removed a spicule of bone 3 cm. long and 1 cm. broad. The sharp end was deeply embedded in the left wall of the oesophagus, and on gently dislodging it with Paterson's forceps

about an ounce of intensely foul pus escaped. When the flow had ceased liquid nourishment was administered through a stomach tube passed through the oesophagoscope. The following day sips of sterilized water were allowed and nutrient enemata administered. The patient recovered slowly but completely from his septic intoxication and left the home a week later.

CASE V.—*A denture which lodged in the oesophagus but passed into the stomach and remained there for nine weeks—the result of a delayed oesophagoscopy.*

History.—Shortly after midnight on January 13th, 1927, I received a telephone message from the hospital to say that a woman, aged 51, had swallowed her denture and that it could be seen on the screen in the cervical region of the oesophagus. From a considerable experience of this type of accident, and having been assured that the denture had no hooks, I felt confident it would involve no risk if it were allowed to remain *in situ* for a few hours longer. At 9 o'clock the same morning I passed an oesophagoscope, but found nothing in the whole length of the gullet. Later the same day the patient was again *x*-rayed, and the foreign body could be seen in the stomach, and here it remained until it was passed with the stools on March 22nd. In the meantime it had caused no trouble to the patient but an uneasiness in my mind which increased as week by week passed by, and this was not relieved by a surgical colleague who suggested that artificial teeth in the stomach might possibly be regarded as an "accessory organ of digestion." I presume he had in mind the gizzard of a bird.

The method which finally proved successful in getting rid of the denture was, in my experience, novel. The patient was given pieces of gauze to swallow, each being 6 in. by 3 in. and two layers thick, with each meal, and after five to six days the foreign body was evacuated and found to be entangled in some of the gauze.

CASE VI.—*Removal of a papillary granuloma from the proximal end of the right bronchus by peroral bronchoscopy: Recovery.* (Figs. 2 and 3.)

In March, 1918, Captain R. was "gassed" and kept in bed for a fortnight, and then invalided home for twelve weeks. During this time he noticed difficulty in breathing when he hurried, and in the following October there was occasional blood-spitting in the morning. He was demobilized in January, 1919, as C1, with 20 per cent. disability, though still dyspnoeic on exertion. In May, 1913, there was stridor on walking and much yellow expectoration. On June 16th he had marked stridor with impeded inspiration and expiration and distressing cough when lying down; there was recession of the supraclavicular fossae on inspiration, with feeble breath sounds around the root of the right lung. Bacteriological examination of sputum showed no tubercle bacilli, but numerous *M. catarrhalis*, streptococci, and coliform bacilli. The radiographer reported "some evidence of infiltration of the mediastinal contents at the level of the manubrium sterni."

On this same date (June 16) I saw him with Dr. MacWhirter of Clapham Common, and the mere exertion of walking into my house caused the patient extreme dyspnoea with both inspiratory and expiratory stridor. The laryngoscope revealed a reddish tumour at the lower end of the trachea, which moved downwards and upwards with inspiration and expiration, suggesting that the growth was pedunculated. Therefore we were confronted with what may be termed an "autogenous foreign body." We sent him straight into a nursing home, and the next day I removed the tumour by direct peroral bronchoscopy. In spite of the preliminary and free application to the growth of cocaine and adrenaline solutions, the first grasp of it in Paterson's forceps caused very free and a somewhat alarming degree of bleeding. This caused many delays, but ultimately all traces of the tumour were removed, and the patient made a rapid recovery and left the nursing home four days later. On September 28th, more than three months later, he expressed himself as being "as fit as I have ever been in my life."

The late Professor Shattock examined a portion of the tumour and described it as a "papillary granuloma." He agreed with the suggestion that it probably arose from proliferating granulations growing from a small ulceration caused by the inhalation of mustard gas.

I cannot recall any operation which gave me more anxiety during its performance or gratification on its successful issue. The physical distress of the patient was obvious and only equalled by a bravery and self-control which had not been undermined by months of suffering. The bleeding of the tumour from the moment it was seized was so free that it not only blotted out the restricted field in which one had to work but threatened an additional and possibly immediate danger if the left bronchus had become blocked by a clot. The pedicle of the tumour was attached to the posterior wall of the right bronchus close to its tracheal margin.

To these sources of mental anxiety were added the extremely tiring effect on the left arm of maintaining the bronchoscope in position in a man with a short, thick neck and a perfect set of teeth. (Endoscopists know full well how much easier it is to manipulate the direct tube in an edentulous patient.) Finally, the operation was performed during a heat wave, so that those who were actively engaged during the operation were eventually reduced to a condition of complete exhaustion.

(For fuller details of this unique case see the *Journal of Laryngology and Otology*, January, 1920.)

REFLECTIONS AND DEDUCTIONS.

The outstanding lesson which the history of these cases teaches is the *danger of delay*, with its obvious corollary that intervention should be immediate when the presence of a foreign body in the lower air passages or in the oesophagus has been diagnosed or even suspected from the history, the nature of the symptoms, or the results of radiographic examination.

What are the chief dangers and difficulties which may be engendered by delay?

1. *Shifting of the Position of the Foreign Body.*

If it has been proved by any or all of the methods of examination to have recently lodged in a bronchus, a violent fit of coughing may expel the foreign body upwards into the glottis or its immediate vicinity and cause a glottic spasm which may prove fatal in a few minutes.

Should the foreign body be like a nail or large-headed pin, which most frequently descend head first, severe coughing will with deep inspiration and forcible expiratory efforts often tend to make the object pass deeper and deeper by a kind of ratchet movement. It is needless to point out that a foreign body primarily lodged in a main bronchus would be infinitely easier to remove than when delay has allowed it to pass downwards into a smaller secondary bronchus (see Case 1).

Again, an object at first detected in the lower airways may be coughed up and then swallowed, so that an unnecessary and fruitless search with the bronchoscope may result from a policy of waiting. Furthermore, it may be expelled from one bronchus and find its way into the other.

In the case of the oesophagus the passage of the foreign body into the gastro-intestinal tract frequently causes no trouble, especially if there are no sharp projections to impede its progress (Case v). Indeed, it is surprising what large objects have been swallowed and recovered later from the stools. It was probably with such experiences in his mind that an American general practitioner said, after looking over a large array of endoscopic instruments, "Waal, the best foreign body catcher I know of is the old-fashioned English bed-pan."

If it were established that a needle had passed into the stomach the question would arise, "Which is the greater risk, a laparotomy or the danger of perforation during the passage downwards of the foreign body?" Fatalities have followed perforation of the bowel by a needle, and knowing this the surgeon may be tempted to explore, but even with the help of an expert radiographer it may be very difficult to locate the exact portion of the small bowel in which the foreign body lies. Possibly it might be well to have the patient radiographed at least every day and for the surgeon to wait at any rate so long as the object continues to move downwards.

2. *The Swelling and Maceration of a Soft Foreign Body.*

Amongst the most difficult and dangerous objects which may enter the lower airways are those which quickly swell and become soft, such as a pea, bean, or nut kernel. Such an accident demands immediate intervention. Delay means maceration, and even with the highest skill particles may escape the most cunningly devised instrument and set up a diffuse and fatal form of bronchitis or broncho-pneumonia. From this point of view the peanut has a particularly evil reputation amongst our American colleagues.

3. *Septic Foreign Bodies.*

One of the most dangerous of these when it gains access to the lower air passages is a septic tooth or "filling" which has slipped from the forceps during extraction. In no circumstances should hesitation in searching for it be countenanced, because serious pulmonary symptoms of a septic nature are liable to set in very quickly, and the

rapid development of local inflammatory reaction around such a foreign body may render its detection and removal very difficult.

Cases III and IV prove how rapidly a sharp foreign body lodged in the oesophagus may endanger the life of the patient. In each case another day's delay might have meant the commencement of a quickly fatal mediastinitis. Valuable time should not be lost in trying the effect of quantities of new bread or other stodgy forms of food. The word "criminal" is scarcely too strong a term to use for the employment of bougies to push blindly the foreign body downwards or of probangs to draw it upwards. I am quite aware that many cases could be quoted in which these methods have been successful, but they involve a grave danger which it is not fair to risk if the safer and more certain procedure of direct endoscopy be available. Is this too great an assumption? I do not think so, because in these days of telephonic facilities and rapid transport, with skilled endoscopists in almost every city and large town, help would be available without dangerous delay. It may be asked, What should be done in a case of laryngeal spasm or severe stridor when delay seems out of the question and no skilled endoscopist could be obtained for hours or even a day? The obvious answer is, "Do a low tracheotomy." By this the risk of suffocation would be removed, and if the tracheal wound be held well open during any coughing fit the foreign body may be expelled through it or driven against it so that it can be removed. Should these desirable ends not occur, the later bronchoscopy will be very much easier because the tube can be passed through the tracheotomy wound instead of through the mouth, and a novice could scarcely fail in such circumstances to see and remove the *corpus delicti*.

As a pregnant instance of the danger of blind bougieing in the oesophagus the following case may be quoted. The patient was a middle-aged man, who was brought into University College Hospital in a moribund condition and with the history that he had swallowed his denture (Fig. 5, No. 15) during sleep two nights before admission. The morning after the accident two prolonged but ineffectual attempts had been made with bougies to force it into the stomach. On admission to hospital we were able to remove the denture by oesophagoscopy within five minutes. Pulmonary symptoms of a septic character developed, and the patient died on the third day. *Post-mortem* examination revealed two large sloughing perforations in the cervical portion of the gullet, and it was obvious that through one of these the bougie had passed four inches downwards into the left mediastinum. There was a large effusion of purulent fluid in the corresponding pleural cavity. Comment is needless. (For fuller details see *Lancet*, February 23rd, 1918.)

4. *The Significance of Certain Symptoms.*

The sudden onset of a cough in an otherwise normal patient should always arouse suspicion, and particularly in the case of children who, from fear of punishment or from ignorance, may afford no history of the accident. This difficulty will obviously arise if, unbeknown to the nurse, a foreign body be inhaled or swallowed before the child has begun to talk. I once removed the teat of a "comforter" from the oesophagus of an infant 4 days old; it had completely prevented nursing at the breast and, but for the fortunate confession of the nurse, more serious results might have followed.

Reference has been made already to the need for care in diagnosis when with cough and other symptoms suggestive of tuberculosis no tubercle bacilli have been found after repeated examinations of the sputum. Suspicion should be all the stronger if the physical signs in the chest be limited to one of the lower lobes of the lungs. In all such doubtful cases the services of a skilled radiographer should be insisted upon, and if his report be negative a careful examination should be made with the bronchoscope.

5. *The Silent Period.*

It not uncommonly happens that the first symptoms of irritation, such as cough, wheezing, and shortness of breath, pass off when the mucous membranes have become tolerant of the presence of a foreign body, and a latent or silent period follows. Too frequently this lulls both patient and surgeon into a sense of false security, with consequent dangerous optimism and delay. Such latent periods may last for hours, days, weeks, or years, but the day of reckoning is almost inevitable, and the technical difficulties of direct endoscopy, when this is ultimately carried out, may be increased to such a degree as to involve risks which would not arise in an early intervention.

6. *Increased Difficulties of Treatment.*

Cases I and II show that when a foreign body lodges in one of the bronchi prolonged delay in its removal will afford time for the formation around it of vascular and oedematous granulations which not only obscure the object but hinder its removal because of the profuse bleeding and secretion which must be controlled before the foreign body can be seized and withdrawn. If impaction has lasted long enough for cicatrization of the granulations to occur, the surgeon may be faced with the great difficulty of dilating a stricture before the release of the foreign body is possible.

Radiography.

There can be few exceptions to the rule that in every case where a foreign body is known or suspected to have been inhaled or swallowed the services of an *expert* radiographer should be enlisted. I emphasize the qualification because a poor skiagram is misleading and often worse than useless. In Case II the boy's chest was *x*-rayed shortly after the accident, but the heart and the neighbouring bronchial regions only revealed a homogeneous deep black shadow. It was assumed that no foreign body was present, and this resulted in twenty-one months' delay during which the patient suffered from serious pulmonary symptoms. Dr. Salmond's radiograph showed the paper-fastener very clearly through the heart substance, and a few days later it was removed. (See BRITISH MEDICAL JOURNAL, November 18th, 1922.)

Should there be an interval between the primary radiographic detection of the foreign body and the operation for its removal a second exposure should be carried out immediately before bronchoscopy or oesophagoscopy, because the foreign body may have moved from its original position. Had this been done in Case V oesophagoscopy would have been unnecessary.

It may be asked, Of what value would radiography be in the case of bodies not opaque to the *x* ray, such as *fish-bones, bone buttons, glass beads, vegetable substances*, macerated meat, etc.? The answer is, In such cases, though the object itself may not be rendered visible by radiography, its *position* can often be indicated.

(*a*) *Lung.*

If a foreign body so completely blocks a main bronchus that no air can enter or leave it, the lung tissue will soon give the physical signs and symptoms of atelectasis, and the radiogram will reveal a characteristic shadow. A more restricted effect will naturally result if a secondary bronchus be obstructed.

Should the object be of such a shape that air can be inspired through but not expired from a primary or secondary bronchus an obstructive emphysema beyond the location of the foreign body will result, and will be manifested if good radiograms be taken; these must be made with the shortest exposure, at the moment of full inspiration and deep expiration.

In the case of smaller non-opaque bodies which permit of unimpeded ingress and egress of air, the insufflation of bismuth subcarbonate or the injection of lipiodol may render its location determinable.

For fuller information on these problems and their treatment readers should refer to the masterly exposition of the subject by Chevalier Jackson in the BRITISH MEDICAL JOURNAL of October 17th, 1925.

(*b*) *Oesophagus.*

When such objects as spicules of bone or other non-opaque bodies are lodged in the gullet, a swallowed capsule of bismuth may be seen by the *x* rays to be held up at a definite spot. Small pledgets of wool soaked in bismuth

solution and swallowed may be caught up in the same way (H. K. Wilson). Bone buttons can frequently be detected after the swallowing of a bismuth solution.

Whether the foreign body be located in the larynx, the trachea, the bronchi, or the œsophagus, an antero-posterior and a lateral or lateral oblique *x*-ray examination should always be made. A comparison of the results thus obtained may be of the utmost value to the endoscopist.

Radiography is indeed the handmaiden of endoscopy, and her aid has often been and will continue to be of indispensable assistance in this branch of surgery.

In conclusion I make no apology for omitting any description or illustrations of the many types of endoscopes and instruments used with them; they can be seen in the surgical instrument catalogues, their number is legion, and they increase more rapidly than the foreign bodies which they are devised to deal with. Still less would it be worth while to dwell on the details of manipulative technique, because these can only be acquired by patient and painstaking practice.

My object will be attained if those who have glanced through the histories of the cases which I have reported will learn from them some of the lessons which it has seemed worth while to emphasize.

NORMAL CHOLECYSTOGRAPHY.*

BY
FRANCIS DAVIES, M.D.LOND.
(From the Anatomy Department, University College, London.)

(*With Special Plate.*)

ON examining a number of cholecystograms it at *once* becomes evident that the shadow of the gall bladder varies in different individuals, both in size, shape, position, and density. Dr. Evarts Graham,[1] the pioneer of cholecystography, predicted in an earlier paper that the shadows of gall bladders would probably be found to vary in position with the different types of bodily habitus. This preliminary report is concerned with the cholecystographic investigation of 100 medical students at University College, London, after administration by the mouth of sodium tetra-iodo-phenol-phthalein, in the endeavour to determine primarily whether the characters of the shadows of gall bladders in normal individuals vary with the different types of bodily habitus. Comment is also made on the oral administration of the dye, and on the details of the radiological technique employed.

1. *Relation of Gall-Bladder Shadows to Bodily Habitus.*

The students, whose ages varied from 18 to 30 years, comprised 80 males and 20 females, and they were classified after the manner of Mills into the following types of bodily habitus. Mills[2] gives the chief characteristics of each of these types as follows (Fig. 1):

1. *Hypersthenic.*—Massive physique, great body weight, heavy bony framework, short wide deep thorax, relatively long abdomen of greatest capacity in upper zones, subcostal angle very obtuse, lungs wide at bases and contract sharply to apices which project but little above clavicles, long axis of heart nearly transverse, alimentary tract high in position, gastric motility fastest and tonus most marked of any type (stomach emptying time about 4 hours 22 minutes), colon high and short, caecum well out of iliac basin (even standing), transverse colon truly transverse, marked colonic tonus, and motility rapid. This group comprises about 5 per cent. of individuals.

2. *Sthenic.*—Resemble hypersthenic but characters less marked; considerable body weight, rather heavy bony framework, thorax somewhat short and deep, lungs widest at bases, heart moderately transverse, subcostal angle about 80 degrees, digestive tract high with good tonus, and motility fairly rapid (stomach emptying time about 4 hours 46 minutes). This group comprises about 48 per cent. of individuals.

3. *Hyposthenic.*—Frailty of build approaches that of asthenic type, visceral characteristics approach those of asthenics, but lack the extremely low position and peculiar form of such; tonus rather poor and alimentary motility somewhat slow (stomach emptying time about 5 hours 26 minutes); lungs intermediate in proportions, heart pendent. This group comprises about 35 per cent. of individuals.

4. *Asthenic.*—Frail slender physique, light body weight, delicate bony structure, long narrow thorax, short abdomen of least capacity in upper zones, marked disproportion between great pelvic capacity and capacity of upper abdomen (pelvis may be as wide and capacious as that of a hypersthenic of twice the body weight); subcostal angle narrow, lungs widest in upper zones and apices extend well above clavicles, heart pendent ("drop-heart"); gastro-intestinal tract low, stomach often largely pelvic when standing, colon long, caecum capacious and low in pelvis, poor tonus and motility slowest (stomach emptying time about 5 hours 43 minutes, and often not empty after 6 hours). This group comprises about 12 per cent. of individuals.

In the investigation here described radiograms of the gall bladder were taken, after administration by the mouth of sodium tetra-iodo-phenol-phthalein, with the radiological technique described below. The data obtained from the cholecystograms are given in the table. From these data the following deductions may be made.

1. The length of the gall-bladder shadow is not definitely related to the type of bodily habitus.

2. The breadth of the gall-bladder shadow is greater in the "better" types of bodily habitus (that is, in the hypersthenic and sthenic types).

3. The neck of the gall-bladder shadow lies at a higher level and at a greater distance from the mid-line of the vertebral column in the "better" types of bodily habitus.

4. The fundus of the gall-bladder shadow lies at a higher level and at a greater distance from the mid-line in the "better" types of bodily habitus.

5. The rate of emptying of the gall bladder (as indicated by the extent of reduction in the size of the shadow at 16½ hours—that is, two hours after taking a fatty meal) is quicker in the "better" types of bodily habitus.

6. The respiratory excursion of the gall-bladder shadow is greater in the "better" types of bodily habitus.

It must be noted that, though this table indicates that the length of the gall-bladder shadow is not definitely related to the type of bodily habitus, the *actual* length of the viscus may vary with the type of bodily habitus, because in the radiograms we have a more foreshortened view of the gall bladder in the "better" types of bodily habitus.

* This work was made possible by a grant from the Medical Research Council.

Table of Results in Various Types and at the Intervals Specified after Administration by the Mouth.

Type of Bodily Habitus.	No. of Cases.	Length of Gall-Bladder Shadow (Inspiration).	Maximum Breadth of Gall-Bladder Shadow (Inspiration).	Position of Neck of Gall Bladder at 1⅔ Hours (Inspiration).	Position of Fundus of Gall Bladder at 1 ½ Hours (Inspiration).	Respiratory Excursion.
Hypersthenic	6	1½ hrs.: 4.9–9.8 cm. 16½ hrs.: 2.6–5.3 cm.	1⅔ hrs.: 2.8–3.7 cm. 16½ hrs.: 1.2–1.9 cm.	Upper part D12—lower border L1 3.1–5.8 cm.	Lower part L1—lower border L3 4.2–8.5 cm.	2.5–4.9 cm.
Sthenic ...	44	1½ hrs.: 4.9–8.5 cm. 16½ hrs.: 2.8–6.1 cm.	1½ hrs.: 2.6–3.7 cm. 16½ hrs.: 1.2–2.8 cm.	Lower border D12—middle L2 2.2–5.6 cm.	Upper part L2—upper border L4 3.8–6.9 cm.	2.5–4.2 cm.
Hyposthenic ..	17	1½ hrs.: 5.1–8.0 cm. 16½ hrs.: 3.5–5.9 cm.	1½ hrs.: 2.5–3.5 cm. 16½ hrs.: 1.4–2.7 cm.	Middle L1—lower part L2 2.7–4.8 cm.	Lower part L2—middle L4 3.5–5.0 cm.	1.9–2.7 cm.
Asthenic ...	5	1½ hrs.: 6.0–9.8 cm. 16½ hrs.: 4.9–7.8 cm.	1½ hrs.: 2.0–2.6 cm. 16½ hrs.: 1.1–1.9 cm.	Upper border L2—lower border L2 2.7–4.0 cm.	Middle L1—lower border L4 3.4–4.5 cm.	1.5 cm.

NORMAL CHOLECYSTOGRAPHY.

Fig. 2 shows the areas including the varying positions of the neck and fundus of gall-bladder shadows in each type of bodily habitus—for example, the neck and fundus of the gall-bladder shadow of a hyposthenic individual will normally be found to lie within the area 1. Fig. 3 shows an average gall-bladder shadow for each type of bodily habitus, the measurements being obtained from the averages of those in the table.

Mills showed that gastric motility and tonus varied with bodily habitus, the motility being fastest in the "better" types. The rate of emptying of the gall bladder is shown above to be quicker in the "better" types of bodily habitus. A definite correlation is thus indicated between gastric motility and rate of emptying of the gall bladder.

FIG. 1.

2. *Method of Administration.*

A dose of 5 grams of sodium tetra-iodo-phenol-phthalein was given to each student. It was made up in five gelatin capsules, each of which was coated a few hours before administration with stearic acid, the coating being thin and uniform. The capsules were swallowed at intervals during the course of the 7 o'clock evening meal, a fair quantity of water being drunk with the meal. To minimize evil effects, the student was advised to remain comparatively quiet during the evening. The following morning, without breakfast, the student presented himself for x-ray investigation at 9.30 o'clock (that is, 14½ hours after taking the dye). Then he took a fatty meal consisting of eggs, bacon, milk, cream, butter, etc., and at 11.30 presented himself for the second x-ray investigation (that is, 16½ hours after taking the dye, or 2 hours after the fatty meal). He then resumed his normal life. A dose of 5 grams is quite sufficient, as it was noted in a number of cases which showed a good gall-bladder shadow that some of the dye was still residing unabsorbed in the large intestine. Moreover, the more serious of the toxic symptoms that have been reported have generally been observed after larger doses. In this series of cases, with the above dosage and method of administration, toxic symptoms resulted in very few instances, and in these they were very mild, not sufficient to interfere with the work of the student or to cause any student to refuse to take the dye a second time if required. The symptoms comprised slight nausea shortly after swallowing the capsules (in 8 per cent.), slight vomiting soon after taking the dye (in one case), slight epigastric discomfort during the night (in 7 per cent.), slight headache in the morning relieved by breakfast (in 10 per cent.), or a nasty taste in the mouth in the morning variously described as "iodoform" and as "metallic" (in 10 per cent.). The dye is a natural purgative, and slight laxity of the bowels (not actually amounting to clinical diarrhœa) was exhibited in 20 per cent. of the cases. Recently I have been using a form of sodium tetra-iodo-phenol-phthalein which is almost free from toxic effect when administered as above described. Slight headache may occur, but is quickly dispelled by 10 grains of aspirin.

3. *Radiological Technique.*

The following points are emphasized in the standardized technique which we have gradually come to employ. For this credit is due to Mr. Frederick Melville, radiographer at University College, London.

1. The tube should be centred over a point about a hand's breadth to the right of the spine of the second lumbar vertebra.
2. The radiogram is taken postero-anteriorly (P.A.)—that is, abdomen towards film.
3. The radiogram is taken at the end of inspiration.
4. The use of the immobilizing band is no definite advantage.
5. The Potter-Bucky diaphragm is always used.
6. Four types of tubes were used with no material difference in the results.
7. Tube condition: 30 milliamperes, 5-inch spark gap, tube distance 36 inches, exposure 4 to 6 seconds (depending on the size of the individual).

It will be noted that the tube distance is great (36 inches), the result of which is to reduce distortion. It was observed that the best cholecystograms were obtained in those films which did not show first-class bone definition—that is, those in which a smaller tube penetration was used as a result of the small spark gap (5 inches).

Comment.

In this investigation a positive "good" shadow of the gall bladder was obtained in 72 per cent. of the cases. This figure includes only those shadows from which definite measurements could be taken. Ill defined or doubtful shadows are not included. The number of positive results in the earlier cases was affected by the fact that the technique was somewhat experimental. It was necessary to determine by experience the best method of administering the dye and the most suitable radiological technique. The later cases showed a larger number of positive results. When the improved (and now constant) technique was employed it was found that of fifteen students who failed to give a positive result on the first investigation, nine gave

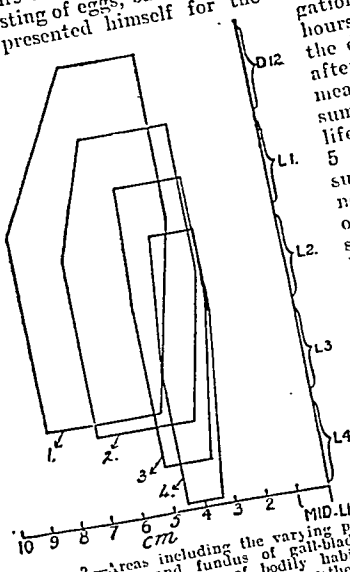

FIG. 2.—Areas including the varying positions of neck and fundus of gall-bladder shadows for each type of bodily habitus. 1, Hypersthenic; 2, sthenic; 3, hyposthenic; 4, asthenic.

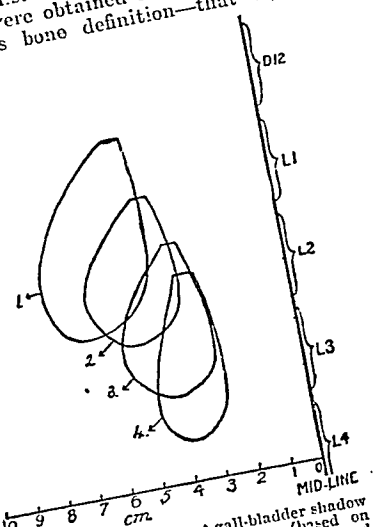

FIG. 3.—Average type of gall-bladder shadow for each type of bodily habitus (based on average position of neck and fundus and average breadth). 1, Hypersthenic; 2, sthenic; 3, hyposthenic; 4, asthenic.

a good gall-bladder shadow when the investigation was repeated six to twelve weeks later, using precisely the same technique. This is a matter of some importance, since many investigators have declared that the absence of a positive result with a reliable technique is the most certain evidence of disease of the biliary tract. The above evidence shows that a certain number of normal individuals may fail to give a positive cholecystogram on the first investigation, but give a good gall-bladder shadow on repeating the investigation some time later. Also in this series it was noted that two students who had previously given positive cholecystograms failed to give a shadow when the investigation was repeated a few weeks later, using the same technique. Evidently, therefore, the factors concerned in the production of a gall-bladder shadow must be liable to physiological variation. The following physiological factors are essential for the production of a positive cholecystogram after the oral administration of sodium tetra-iodo-phenol-phthalein:

1. A definite rate of absorption of the dye from the intestine.
2. A definite rate of specific excretion of the dye by the liver.
3. Entrance of the dye into the gall bladder in sufficient amount.
4. A definite degree of concentration of the dye-containing bile by the gall bladder.

It is possible that any of these factors may be subject to physiological variation which may affect the production of a positive cholecystogram. Have we any means of determining the adequacy of each of these factors and thus of observing any possible variations that may occur in the normal individual? It might be possible to obtain an index of the rate of absorption of the dye from the intestine by observing the rate of elimination in the urine (a small fraction of the dye being eliminated by this channel). The dye has a slight laxative action on the bowel and the greater part of the dye is eliminated in the faeces. No definite correlation between the degree of laxative action of the dye and the density of the shadow of the gall bladder was noted in this series. The rate of excretion of the dye by the liver can be checked by Rowntree's method of estimating the "global capacity" of the liver to eliminate similar dyes—for example, phenoltetrachlorphthalein. This is done by injecting intravenously a known quantity of a solution of this dye and estimating its rate of disappearance from the blood stream, or its rate of appearance in the contents of the duodenum aspirated through an Einhorn's duodenal tube. The filling of the gall bladder with dye-laden bile from the liver is brought about by a mechanism at the termination of the common bile duct which resists the passage of bile direct to the duodenum. It is possible that this resistance mechanism may be liable to physiological variation. As Mann[3] states, it is not known what percentage of bile normally enters the duodenum without previously entering the gall bladder. The dye in the bile leaving the liver is not sufficiently concentrated to produce a shadow. The concentration takes place in the gall bladder by the absorption of water by the wall of the viscus. For a sufficient degree of concentration to take place the wall of the gall bladder must be healthy, but the process may be liable to physiological variation. The degree of absorption of water by the gall bladder may be affected by the water content of the tissues at the time. There may be other factors, besides those mentioned, which are necessary for the production of a gall-bladder shadow, and physiological variations in these may likewise modify the results of an *x*-ray investigation of the biliary tract.

The complexity of the physiological processes underlying the production of a gall-bladder shadow is such that even on prima facie grounds the statement that absence of a shadow (*per se*) always indicates a pathological state seems unwarranted. Moreover, the above observation that a normal individual may fail to give a shadow on the first investigation but give a positive result on repeating the investigation is in direct conflict with such a statement. It thus appears that a negative cholecystogram *per se* (that is, in the absence of clinical evidence of disease of the biliary tract) is of less diagnostic value and significance than positive cholecystographic evidence of disease. Likewise, if a shadow be produced, the above factors will undoubtedly have an influence upon the density of the shadow, so that too much weight must not be attached to diminished density of the shadow as an indication of a pathological state.

Summary and Conclusions.

1. The position of the gall-bladder shadow in cholecystograms varies with the type of bodily habitus. (See Fig. 2.)
2. The rate of emptying of the gall bladder varies with the type of bodily habitus. A correlation is established between bodily habitus, gastric motility, and the rate of emptying of the gall bladder.
3. The oral method of administration of sodium tetra-iodo-phenol-phthalein, using the technique described, is reliable, safe, and comparatively free from toxic effects.
4. The radiological technique described is reliable.
5. A certain number of normal individuals may fail to give a shadow on the first investigation, but on repeating the investigation with precisely the same technique many of these may give a positive result.
6. A negative cholecystogram, in the absence of clinical evidence, is less reliable than positive cholecystographic evidence of disease.

I desire to express my thanks to my chief, Professor G. Elliot Smith, at whose suggestion this work has been carried out, and to Mr. H. A. Harris for valuable advice and help in the investigation. I also wish to express my appreciation of the medical students of University College who offered themselves as subjects for this investigation.

TWO CASES OF THROMBO-ANGIITIS OBLITERANS IN WOMEN.

BY

E. D. TELFORD, M.A., F.R.C.S.,

PROFESSOR OF SYSTEMATIC SURGERY, UNIVERSITY OF MANCHESTER;

AND

J. S. B. STOPFORD, M.D., F.R.S.,

PROFESSOR OF ANATOMY, UNIVERSITY OF MANCHESTER.

(With Special Plate.)

THE symptoms of thrombo-angiitis obliterans are already becoming widely known, thanks to the reporting of cases by several observers, and it is not likely that much more is to be gained by the bare recording of further instances. The rarity of the lesion in women is, however, one of the extraordinary features of the disease. Buerger,[1] to whom much of our knowledge of the subject is due, states: "So rare is the disease in females that doubt has been cast on the possibility of its occurrence outside of the male sex." He further states that he has observed only three cases.

In the course of further investigation of thrombo-angiitis obliterans we have encountered two instances of the disease in women. These we think worthy of being recorded, not only by reason of their rarity in that sex, but because each presents certain very unusual features.

Dr. Williams of Salford drew our attention to the case of a woman patient who had continued for no less than twelve months with the left hand, wrist, and part of forearm in a condition of total mummification. By the kindness of Dr. Williams we were able to make an examination of the case and to obtain a photograph. Short details of the case are as follows:

A married woman, aged 52, British born, stated that her trouble began, some fifteen months ago, with severe aching pain in the index and middle fingers of the left hand; she noticed that they were "slightly blue." Within three weeks the whole hand was aching very severely; it was "cold and dark red." She continued in this way for three months, and at the end of this time the hand, wrist, and lower part of the left forearm were in a condition of black-dry gangrene. The pains then ceased, and when we saw her the condition of the limb had shown no change

whatever for twelve months. The state of the hand is well shown in the photograph (see Special Plate).

Her previous medical history was good and without incident; she had had eight healthy children, all now grown up. For the greater part of her life she had worked in a dye works, with her hands continually in cold running water.

The condition of the heart is normal, and the state of the pulse in the main arteries is as follows: In the affected arm the pulse fails entirely just below the clavicle, and no pulse is to be felt in any vessel of the limb. The pulse in the head, neck, and right arm is normal. In both lower extremities a slight pulse can be felt in the popliteal artery, but at no other point below this. In all that part of the left arm which is alive sensation is normal, as tested by touch, heat and cold, pain, and joint sense. No active treatment was urged as the gangrenous hand was giving no trouble and the patient's general condition was poor; she died shortly afterwards from "malignant ovarian cyst." Unfortunately it was not possible to obtain specimens of the blood vessels for examination.

We owe the opportunity of studying the second case to Dr. Wilson of Cheadle, who informed us that he had under his care a woman in whom he was unable to feel a pulse in either arm. A short summary of the case is as follows:

A married woman, aged 48, British born, first noticed weakness of the left hand six years ago; this weakness progressed, and there was tingling and aching of the forefinger. Within a year the right arm followed the same course as its fellow, but the trouble on this side has never been so severe.

Examination of the arms shows that both are weak and much wasted. There is no alteration of sensation and no sign of any nervous lesion. No discoloration or other gross evidence of circulatory trouble is apparent. The extraordinary fact is that at no point in either limb can any subclavian, axillary, brachial, radial, or other pulse be found. The pulse in the head and neck is normal. The patient stated that her legs were very easily tired, and "often went to sleep." In the right lower extremity a very diminished and feeble pulse can be felt in all the large vessels, whilst on the left side no pulse is felt in or below the popliteal artery. The superficial and common femoral pulses on this side are very faint.

It may reasonably be objected that in the absence of histological proof these two cases may not be true instances of thrombo-angiitis obliterans. We think, however, that they must be regarded as such, and from what is now a fairly extensive experience of the disease the clinical features of these cases leave no doubt in our own minds.

Their interest lies, not only in the rarity of the disease in women, but in the fact that the two patients illustrate very opposite types. Cases of thrombo-angiitis obliterans have been noted to vary in intensity and rapidity of development within very wide limits, and we have in these two patients almost the extremes of acute and chronic types. In the first case the period between the onset of symptoms and the occurrence of total gangrene was but three months. In this patient the thrombosis had spread throughout the arm with such rapidity as to preclude entirely any successful attempt at collateral circulation. In the second case the course is extremely chronic. The patient dates her symptoms from six years ago, and it is evident that the change for the worse has been very slow. Whilst there is no pulse to be felt in either arm, it is plain that plenty of time has been given for the setting up of a good collateral circulation. There is, in fact, evidence that the history of this case is in reality very much longer than six years. The patient states that at her last confinement both doctor and nurse were surprised to find that no pulse could be found in either arm; this confinement was no less than sixteen years ago.

We are as yet no nearer to the cause of this strange disease. It is by no means peculiar to the Jewish race; all our cases have been of pure British blood. Meleney and Miller[2] describe twenty-four cases from Peking, and Whyte[3] in two papers has reported many cases in Chinese patients. He says that the disease occurs in nearly all the provinces of China. All observers are agreed that it appears to have no relation to syphilis.

Where so much difficulty exists it is worth while to take note of any suggestions made by the patients themselves, and in this respect four of our patients have attributed their condition to prolonged exposure to cold and wet. An electrical linesman stated that he had worked out of doors in wet clothes for years, and another patient, who was a slater, stated that his affected leg was the one which was always uppermost in his habitual position when slating a roof, and had been often soaking wet for hours together. Another of our patients was a lifelong enthusiast as a fly fisherman, and stoutly attributed his condition to wading, whilst in one of the cases we report above the woman had worked most of her life with her hands in cold running water. We have also seen several cases of thrombo-angiitis obliterans in the lower extremities of pensioners who were exposed to long and frequent spells of cold and wet in trench warfare.

Whilst it is not likely that this exposure is a direct cause, yet it seems possible that it may act as a predisposing factor in susceptible patients. These instances are, however, too few to be worthy of any stress, and we wish to do no more than merely to place them on record as facts which in the history of our cases have emerged with some frequency.

THE ELECTRICAL AND HISTOLOGICAL MANIFESTATIONS OF THYROTOXIC MYOCARDITIS.*

BY

J. STRICKLAND GOODALL, M.B., M.R.C.P.LOND., F.R.S., F.R.C.S.ED.,

PHYSICIAN TO THE NATIONAL HOSPITAL FOR DISEASES OF THE HEART, LONDON, W.,

AND

LAMBERT ROGERS, F.R.C.S.ED.,

ASSISTANT IN THE SURGICAL UNIT, THE WELSH NATIONAL SCHOOL OF MEDICINE, THE ROYAL INFIRMARY, CARDIFF.

(*With Special Plate.*)

THE myocardium resembles other muscles of the body in its properties of irritability, conductivity, contractility, and tone. These are definitely specialized in different regions and fulfil specific purposes in the mechanism of the circulation. For example, irritability is specialized in the region of the sino-auricular node and dominates the beat, the most irritable part of the myocardium always determining the contraction. Tonicity is specialized in the region of the rings, its function being to maintain the competence of the valves. Contractility is specialized in the walls of the ventricles and provides the energy for the circulation, while conductivity—the most differentiated of all the functions of the myocardium—is localized in the special conducting system.

Should the myocardium become poisoned (toxic myocarditis), or degenerated (degenerative myocarditis), the signs and symptoms produced are determined chiefly by this specialization of function. If, for example, the auricle is the part chiefly picked out, auricular phenomena, extrasystoles, auricular paroxysmal tachycardia, flutter, or fibrillation (paroxysmal or established) may result, with the consequent irregularity and rapidity of the pulse. If the bundle of His, or some other part of the conducting system, is affected, one of the specific defects of conductivity—for example, heart-block, main branch or arborization block—may result, with its consequent slow pulse and syncopal attacks; whereas, if the ventricular wall itself is chiefly picked out, ventricular extra-systoles, paroxysmal ventricular tachycardia, or even ventricular fibrillation may ensue.

A general poison, either endogenous or introduced from without, nearly always acts first on some special part of the myocardium, which is determined, not necessarily by any special affinity of the poison, but by a pre-existing damage, strain, or fatigue of the particular part. For example, it is well known that in rheumatic affections of the myocardium digitalis in toxic doses will sometimes couple the beat and sometimes produce heart-block. A coupled beat is, in most cases, due to a dominant beat rising in the sino-auricular node and an ectopic beat rising from

* Abstract of a demonstration at the Annual Meeting, Nottingham, 1926.

the right ventricle; the reason the right ventricle first succumbs to the action of the digitalis is, I think, due to the fact that it is the right heart which is usually strained, fatigued, or damaged in those cases (such as mitral stenosis) to which digitalis is most often administered. On the other hand, the cases which develop heart-block on digitalis poisoning are those in which the bundle of His is relatively most damaged.

Although the above statements are generally true, most slowly acting poisons which affect the myocardium decrease its tone and usually raise its irritability as well. In thyrotoxicosis the first symptom is usually tachycardia, at first intermittent, then continuous, followed in the later stages by cardiac irregularity, myocardial exhaustion, and even sudden death.

Electro-cardiographic Manifestations.

Of the different waves in the normal electro-cardiogram we may say briefly that P equals the auricular complex; Q, R, S, T the ventricular complexes.

In the minor degrees of thyroid poisoning the electrocardiogram shows a tachycardia of physiological type, P, Q, R, S, and T being present, but there are certain definite peculiarities in the form of the curve. Whereas in an effort tachycardia the T wave is always larger than the P, in thyroid tachycardia the T and P are approximately equal, while in mitral stenosis a tachycardia of similar grade is characterized by the P_2 wave being bigger than the T_2. If the tachycardia is of a higher grade the T and P waves are superimposed; it is thus possible to distinguish easily at a glance these three types of physiological tachycardia. The prolonged tachycardia becomes associated with a definite left-sided preponderance, while the continued action of the toxin produces distinct evidence of myocardial damage, the conducting system being specially picked out, so that there is impaired conduction in the bundle of His, the P-R interval being increased in some cases to as much as 0.3 of a second; in other cases the right main branch is picked out, so that there is a definite right bundle block with consequent impaired efficiency in the pulmonary circuit. This is particularly liable to occur in the pneumo-mechanical heart of the toxic adenoma; at a still later date the arborization branches of the bundle of His may be involved.

In the later stages of mild cases of thyrotoxicosis, or in the early stages of very acute ones, the heart may become irregular owing to auricular fibrillation and then the normal co-ordinate contraction of the auricular muscle fibres does not occur; the different bands of auricular muscle contract irregularly and more or less independently. The degree to which this dissociation and inco-ordination has occurred determines whether the resulting fibrillation is of the so-called coarse or fine variety. In my own series of cases 15 per cent. showed auricular fibrillation, 10 per cent. exhibiting the condition before, and 5 per cent. developing it after operation. Generally speaking, the condition develops after the disease has been in progress for some years, and must be regarded as indicating that the myocardium is profoundly poisoned or that degeneration has definitely commenced. Occasionally Graves's disease starts with auricular fibrillation, and in these cases the condition usually persists. Not infrequently (about 5 per cent.) auricular fibrillation develops during or soon after operation on the thyroid, and may occur after any operation, from simple ligation to extirpations of varying extent. Usually the condition is only temporary. Its onset is often synchronous with a rise in blood pressure.

On the other hand, cases of Graves's disease which show auricular fibrillation, which may in some cases have persisted for years, are frequently cured of the fibrillation after removal of the greater part of the thyroid, especially if they are treated by quinidine, which appears to influence materially many of these cases after partial thyroidectomy. The cure of fibrillation by removal of the thyroid is now a recognized treatment. Appended is a summary of the electro-cardiographic findings in 787 thyrotoxic hearts.

Analysis of Electro-cardiographic Findings in 787 Cases of Thyroid Hearts.

	Series.				Total.
	I.	II.	III.	IV.	
Number of Cases	264	225	150	148	787
Preponderance:					
Left	57	41	68	18	184
Right	29	36	24	19	108
P-R+	152	47	9	34	242
Auricular fibrillation	39	25	6	21	91
Branch block, right	—	1	3	1	5
Extra-systole:					
Auricle	—	2	2	1	5
Ventricle	—	7	4	8	19
T waves modified:					
T1	—	14	9	—	23
T2	—	11	35	—	46
T3	—	11	102	—	113
R-S complex abnormal	20	1	12	—	33

The electro-cardiographic findings in these 787 cases may be summarized as follows:

242 cases showed impaired conduction in bundle of His.
184 cases showed a left-sided preponderance.
113 cases modification of the T wave in the third lead.
108 cases showed a right-sided preponderance.
91 cases auricular fibrillation.
46 cases modification in T wave in lead ii.
33 cases showed modification in R-S complex.
23 cases modification in T in lead i.
19 cases ventricular extra-systoles.
5 cases right branch block.
5 cases auricular extra-systoles.

Histological Appearance of Myocardium in Fatal Graves's Disease.

The illustration shows a section of the heart muscle of a woman, aged 21, who died from acute Graves's disease, from which she had been suffering for a year.

She had been in good health until the onset of the disease, and then presented the cardinal signs of goitre, exophthalmos, tachycardia, and tremors. The pulse was fast and regular, and there was no heart-block nor auricular fibrillation. Rest in bed and six months' medical treatment proved ineffective, but at the end of this time she was temporarily improved by polar ligation of the right superior thyroid artery, under local anaesthesia. Six weeks later the left superior artery was tied, but, following this, the thyroidism became more acute. She died forty-eight hours afterwards from failure of the right side of the heart, which at the necropsy was found to be very dilated. The pericardium, endocardium, and valves appeared healthy, and, on cutting the muscle, no gross change was noticed.

The sections, however, show the presence of an active and advanced myocarditis (see special plate), evidenced by the number of polymorphonuclear leucocytes surrounding the vessels and spreading between the muscle fibres, and also by the presence of a patchy necrosis of bundles of muscle fibres. The necrosed bundles have taken the stain badly, are swollen and lack definition, while the nuclei are swollen also.

The part of the heart least affected is the base in the region of the bundle of His; the most marked degenerative change is in the ventricles, particularly the right, where necrosis is most apparent.

Although somewhat similar changes have been described by Continental and American workers, as yet in this country little attention has been drawn to the subject of myocarditis in Graves's disease. The writers have since collected records of eight other cases in which the histological findings were similar to those here described.

CLOSURE OF ABDOMINAL INCISIONS.

BY

F. STRONG HEANEY, M.A., M.D., F.R.C.S.I.,

HONORARY SURGEON, LIVERPOOL STANLEY HOSPITAL.

THE high incidence of faulty wound union in abdominal incisions leaves ample scope for improvement in the technique of closing the abdomen.

A recent American writer[1] found that faulty union *occurred in 12 per cent. of clean abdominal wounds closed* with absorbable sutures. In contaminated wounds, closed in the same manner, the percentage rose to 80 per cent. These figures, he found, could be considerably reduced by using for the fascial layer a continuous suture of twisted silk. The suture was passed through the skin beyond the extremities of the wound, and could thus be removed at a later date. Continuous silk, even though removable, is prima facie not the suture of choice in contaminated wounds.

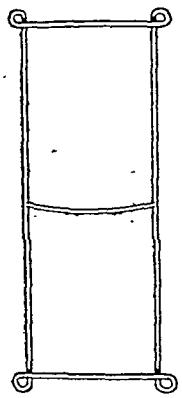

FIG. 1.—Wire frame showing curved cross-bar used when necessary to strengthen sides.

Many surgeons have advocated and used the "figure of 8" silkworm-gut suture for the same purpose. The small deeper loop of the "8" takes in its bight the essential layer—that is, the fascia of the linea alba or other fascial layer concerned—while the larger superficial loop is joined over the skin and encloses all the tissues superficial to the fascia.

This suture has many disadvantages; three may be mentioned: (1) The smaller deeper loop can only be made effective by tying the suture so tightly as to strangle the bulky tissues in the bight of the superficial loop. For this reason the suture could not be employed for, let us say, a vertical incision in the posterior sheath of the rectus. (2) The hold of the deeper loop on the fascia, wherever situated, rapidly becomes slack owing to the yielding of the tissues enclosed in the large superficial loop. (3) In case of suppuration of the abdominal wall—if the superficial loop is released for drainage purposes the fascial support is sacrificed as well.

These disadvantages can be obviated by tying the ends of the "figure of 8" suture over an oblong wire frame resting on the abdominal wall (Fig. 1). The tension of the

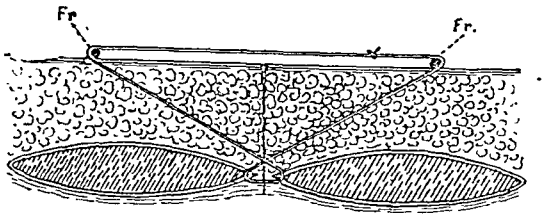

FIG. 2.—Fr.=Cross section of frame.

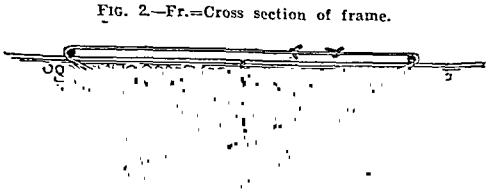

FIG. 3.—The frame is shown in cross section. For convenience the suture in the anterior and that in the posterior sheath are shown in the same horizontal plane.

suture so tied is approximately constant during the two or three weeks it remains *in situ* (Fig. 2). It can be employed for the posterior sheath of the rectus without damage to the muscle fibres (Fig. 3). In case of suppuration free drainage can usually be achieved by removal of superficial sutures without disturbing the fascial supports which are attached to the frame. The frame, far from being a discomfort, acts as a splint supporting the abdominal wall in coughing, vomiting, or distension.

For the larger wounds I have found a frame 7 in. by 3 in. made of No. 10 iron wire suitable in size and strength. For smaller wounds 6 in. by 2½ in. in slightly finer wire suffices. (The frames are obtainable from White and Wright, Liverpool.)

For transverse wounds the frame can be moulded by the hand to suit the curve of the abdominal wall. If likely to cause discomfort by pressure on the pubis or rib margin a corner, or the whole end, can be bent away from the bone. The loops at the corners of the frame prevent the terminal sutures slipping off. It may be an advantage in some cases to tie each suture end to its corresponding side of the frame without crossing over the surface.

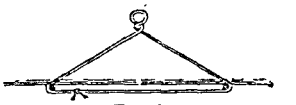

FIG. 4.

I have sometimes used a modified "figure of 8" suture (Fig. 4) which gives a more secure apposition of the fascia. If this modification is used the silkworm-gut should be severed one or two days before it is actually removed.

I do not know whether the method here described is new; it is certainly helpful, whether ancillary to buried catgut in clean cases or without catgut when the wound has been exposed to contamination.

MEDICAL, SURGICAL, OBSTETRICAL.

NEPHRITIS FOLLOWING INFLUENZA.

NOTES ON 100 CONSECUTIVE CASES OF INFLUENZA.

IN December, 1926,[1] I reported four cases of acute haemorrhagic nephritis following attacks of influenza, and when the epidemic was at its height, in January, 1927, I examined the urine in 100 consecutive cases as they occurred in practice. They included 10 children up to 14 years of age (Class I in the table); 76 insured patients, mostly tobacco workers (Class II); and 14 patients over 60 years of age (Class III), some working, some at home.

Influenza does not differ from any other acute infection—for example, pneumonia—in its effect on the glomeruli of the kidney; and when the fever is at its height the urine, as a rule, shows a slight haze of albumin, which, however, disappears with the fall of temperature. Four cases in the series, however, were very different.

CASE I.

A man, aged 22, had a severe influenzal cold with sore throat on January 16th (temperature 103.4° F.). On January 17th epistaxis occurred, and on January 18th severe haematuria. He was obviously very ill, restless, temperature 104° F., pallid, and swollen round the ankles and eyes. Albumin was present in the urine in excess, and the deposit showed red blood corpuscles, leucocytes, cell and blood casts, but no pus. He recovered rapidly from the kidney condition, but on January 27th he began to cough up thick jelly-like haemorrhagic sputum and complained of pain in the right chest. This sputum continued until January 30th. Since then he has made uninterrupted recovery and resumed work on March 28th. His previous health had been excellent, there had been no suggestion of a cardiac lesion, and I have no doubt the trouble in the chest was embolic.

CASE II.

A girl, aged 12, developed a severe influenzal attack with tonsillitis on January 6th; this was followed by tenderness over the liver region. Severe vomiting with marked jaundice occurred on January 7th, the urine showing much bile and some albumin. *The attack subsided on January 10th, and I was astonished*, on examining the urine that day, to find a condition resembling that of Case i—that is, as regards the deposit. This child had a history of rheumatism, and there was well marked mitral disease. She made an excellent recovery.

CASE III.

The mother, aged 48, of Case ii contracted influenza a week after (January 13th). She did not complain of tonsillitis, but almost at once developed haematuria. The deposit was similar to, but not so abundant as in Case ii, but the albuminuria was more persistent and only cleared up finally on March 22nd.

[1] BRITISH MEDICAL JOURNAL, December 11th, 1926, p. 1118.

CASE IV.

A man, aged 26, a tobacco worker, whose previous health had been good, on January 15th developed influenza with severe tonsillitis. His urine showed much albumin, and, microscopically, a few red blood corpuscles. This case has been most persistent. He still complains of weakness, breathlessness on exertion, and is unfit for work. The albuminuria has not cleared up.

One Hundred Cases of Influenza, showing Proportion affected with Nephritis.

	Cases.	Nephritis present.
Class I	10	1
Class II	76	3
Class III	14	0

The bacteriological examination of the urine of the four cases of nephritis mentioned showed streptococci and *Bacillus coli* to be present.

As to the pathology of the nephritis following influenza, I do not think that any doubt can exist that in Case i renal embolism occurred, followed later by pulmonary infarction in the right lung. The other cases described can be explained in a similar way, as Dr. Ambrose W. Owen[2] mentions. Wyllie and Moncrieff[3] think that this haemorrhagic nephritis follows acute tonsillitis in children, but adults are as often affected, in my experience, and sore throat is not necessarily present (Case iii). They, however, agree that the condition is probably caused by renal embolism.

Conclusions.

Influenza causes, like most acute infections, a febrile albuminuria, due to glomerular changes in the kidney. There are cases, however, in which the nephritis is well marked (4 per cent. in my series), either (*a*) haemorrhagic, as in Cases i, ii, and iii, or (*b*) exudative, as in Case iv. Embolism in the renal vessels is the probable cause of this nephritis.

The prognosis is excellent as a rule. I have seen seven cases—*four in children, three in adults*—of haemorrhagic nephritis following influenza since December, 1926, and all have now recovered fully; but persistent albuminuria may occur (as in Case iv) and cause prolonged incapacity.

Southville, Bristol. ARCHIBALD S. COOK, M.B.

GRAMOPHONE NEEDLES IN RESISTANT SINUSES.

THE following case seems noteworthy as showing how far a patient may go in her efforts to prevent recovery and to prolong treatment in hospital.

A woman, aged 32, with a history of tuberculous disease of the left knee and ankle since 1924, had been in a sanatorium for sixteen months with swelling and pain around the joints, and later, discharging sinuses. The knee improved, but early in 1926 she was admitted to hospital on account of the ankle; *x*-ray examination did not show evidence of bone disease and good progress was made under treatment. In a few months she was transferred to a sanatorium where discharging sores again formed over the knee, causing her to be readmitted to hospital. The lesions were small ulcers rather than sinuses, and the bone was not involved; some suspicions were aroused at first and the leg was encased in plaster for a while, to prevent possible interference. The plaster had to be removed within a fortnight owing to the patient persistently complaining of severe pain; but there was not much alteration in the condition of the knee. As time went on the lesions increased in number and were absolutely resistant to treatment. It was thought that they might be lupoid in character. Another focus appeared in the right breast, where a lump formed and broke down; this healed slowly, but the condition of the knee got gradually worse, small abscesses forming periodically. During the whole time the temperature in the evening was slightly raised, with exacerbations, and the pulse rate was slowly increasing.

Subsequent *x*-ray examination showed seven short pieces of needle, resembling short gramophone needles, implanted in the superficial tissues round the patella, all but one perpendicular to the surface. Four of them were close together distal to the patella on the inner aspect, and three level with the patella on the outer aspect. A fragment of needle was also observed in the right breast. The patient denied all knowledge of the needles.

I am indebted to Mr. Wilfred Gostling and Dr. Newbery Fergusson of the honorary staff for permission to publish the case.

CLINICAL AND SCIENTIFIC PROCEEDINGS.

HAMPSTEAD DIVISION.

A MEETING of the Hampstead Division was held at the Central Library, Finchley Road, on May 12th. In the absence of the chairman of the Division, Dr. J. S. Mackintosh, the chair was taken by the vice-chairman Dr. ARTHUR REES.

Immunity to Diphtheria and Scarlet Fever.

Dr. R. A. O'BRIEN opened a discussion on immunity to diphtheria and scarlet fever by means of toxin-antitoxin treatment. In the course of his address, Dr. O'Brien gave a short description of the Schick test and experiences therewith. His conviction of the scientific truth and practical utility of the test and active immunization when properly used and controlled grew more firm each year. He and his colleagues had had under observation since they began this work several institutions in which the use of these measures had enabled the authorities either to abolish diphtheria altogether or, if prophylactic measures had not been previously used, to deal with epidemics with a degree of ease and confidence that was deeply appreciated by those responsible for administrative measures. In institutions where cases were continually occurring, it was important to swab the Schick-negative reactors, for among them would be found the dangerous "profuse" carrier of virulent diphtheria bacilli, if a "carrier" were really the cause of the epidemics. Attempts were constantly being made to simplify the procedures; prophylactic injections were now given to all children available before school age without a preliminary Schick test. The aim of their work was to increase the efficiency of immunization, and to reduce the number of injections. Toxoid, which was of higher efficiency in all laboratory tests, had not been sufficiently tried clinically in England. Mr. A. T. Glenny had now in the press a paper describing the use of the floccules produced by the mixing of *toxoid* and antitoxin following the Ramon toxin-antitoxin technique. It was hoped that this preparation would not produce reactions in adults, and that it might possibly reduce the number of injections necessary to promote immunity. Mr. Glenny had also succeeded in recovering a much purified toxoid, probably entirely free of antitoxin, and this substance had proved to be a potent prophylactic in animal tests.

Dr. O'Brien then gave a short description of the Dick test, and pointed out that in the typical case of scarlet fever the Dick test was almost always positive in the first twenty-four hours of the disease; the Schultz-Charlton blanching of the rash was also positive, and numerous streptococci were present in the culture made from throat smear. The patients during convalescence became negative to the Dick test. Already some hospitals had, by testing nurses and immunizing the Dick-positive reactors, apparently reduced scarlet fever to the vanishing point in hospital personnel. These data were of great importance to the clinician and the administrator. Scarlet fever antitoxin was effective in "toxic" but probably useless in late septic cases. Patients treated with antitoxin *did not* develop their own immunity, and so were more apt to remain Dick-positive and presumably non-immune to the disease than those not treated with antitoxin.

Diphtheria Prevalence and Prevention.

Dr. GRAHAM FORBES, who followed, read a paper on diphtheria prevalence and its prevention in Hampstead. After describing the high incidence of diphtheria of recent years in London, particularly among those under the age of 15, who contributed 76,200 (82.5 per cent. of *the total* cases), and 5,340 deaths (97 per cent. of the total diphtheria mortality), during the seven years 1920-26, he compared its prevalence in Hampstead with that in other metropolitan boroughs. Although the average annual diphtheria attack rate for the past ten years in Hampstead stood at

1.8 per 1,000, or twenty-third in order of attack rate among the twenty-nine metropolitan boroughs, as against 2.65, the mean for all London, the incidence had been by no means uniform. In 1921, a year of greater severity than any since the disease was made notifiable, no fewer than 408 cases were notified in the borough, representing an attack rate of 5.1 per 1,000, and in that year Hampstead stood fourth in order of attack rate among the twenty-nine boroughs. That high prevalence was mainly located in the Kilburn, West End, and Belsize wards, in streets whose population density and overcrowding rate were higher than in any other part of the borough—notably, Netherwood Street and Palmerston Road (enclosing Netherwood Street School), in Kilburn ward; Ravenshaw and Broomsleigh Streets, close to Broomsleigh Street School, in West End ward; and, in Belsize ward, Fleet Road and School provided the majority of the cases. It was noteworthy that the street distribution of diphtheria radiated from the vicinity of the schools, as from separate centres, infection becoming less heavy the further removed from a school. As regards incidence among the child population, whether taken for the 0-15 year period, or actual school population rate, Hampstead presented a much higher figure than the average for all London for the two groups in that particular year (1921). Whereas the ten years' mean rate for Hampstead among those under the age of 15 was 7.4 per 1,000, as compared with 8.2, the all-London mean, in 1921 the figure reached 20.8 (0-15 years) and 28.8 (school age rate) per 1,000, whilst the mean for all London was only 11.3 and 9.3 per 1,000 of the two populations.

Special reference was made to the relationship between population density, overcrowding, and diphtheria incidence, illustrated by maps, charts, and tables thrown on the screen, comparing these factors in the individual wards, in Hampstead as a whole, and in the other metropolitan boroughs. The London boroughs could be divided into five groups, A, B, C, D, and E, showing an ascending scale of density, overcrowding, and diphtheria incidence. The very unequal distribution of diphtheria in the several wards rendered it possible to place each ward in one or other group. The less affected wards—Town, Central, Adelaide, and Priory—with an average population density of 46.6 persons per acre and a ten-year diphtheria attack rate of 1.06 per 1,000, fell into Group B; Belsize and West End wards, with average density of 80 per acre and attack rate per 1,000 of 2.5, into Group C; and Kilburn ward stood alone out of the seven wards in Group E with an average population density of 162.5 persons per acre and an attack rate of 2.75 per 1,000. In that ward was an area of 10 acres formed by four densely populated streets, enclosing Netherwood Street School, and showing a population density as high as 238 persons per acre. Dr. F. E. Screse, the medical officer of health, had stated, in his annual report for 1921, that the severe diphtheria outbreak in that year, when 128 cases were notified in the Kilburn ward alone, was of unusual virulence, and attended by an unusually high case mortality. At one time 50 per cent. of the cases died—evidence presumably of association between population density, overcrowding, and diphtheria incidence influencing the spread of massive doses of infection, whereas in West End ward, although the actual number of cases notified (137) was higher, they were of less severe type, and the mortality was much lower. In the thirteen elementary schools in Hampstead the number of cases of diphtheria in the last ten years, among a yearly average of 6,460 children on the school rolls, totalled 556, of which 186 had occurred in 1921. The schools most affected were "Broomsleigh Street" in West End, with 144 cases in the ten years (average attack rate 16.5 per 1,000), 59 cases in 1921 (attack rate 58); "Netherwood Street" in Kilburn ward, 119 cases in ten years (attack rate 9.7 per 1,000), in 1921 64 cases (attack rate 74 per 1,000); in Belsize ward, Fleet Road School, 108 cases in ten years (average annual attack rate 10 per 1,000), in 1921 16 cases (that is, attack rate of 15 per 1,000).

Dr. Forbes drew attention to the risk of a recurrence of the high wave of infection of 1921, and pointed out that the past two years had shown a rising incidence in the borough. It was significant that the average number of cases per ward for 1926 was 23, the same as in 1920, immediately preceding the outbreak of 1921. The necessity for guarding against that risk was obvious. The time was opportune for the introduction of preventive measures afforded by the use of the Schick test and diphtheria immunization, which had been fully explained by Dr. O'Brien. In ten years diphtheria had, Dr. Forbes estimated, cost Hampstead about £50,000—that is, about £5,000 per annum. The cost of testing and immunizing all the school children in the borough would amount to about £1,000. For the expense incurred by a single case of diphtheria (about £30), 200 children could be tested and immunized. The position of diphtheria immunization in the United States (especially New York City) and in Great Britain was compared and reviewed, and details were given of the success of preventive measures which had already been carried out among the staffs of fever hospitals, in residential institutions, and among school populations in New York, Edinburgh, Aberdeen, and Birmingham.

Dr. Forbes concluded by suggesting the formation of a borough committee, including appointed representatives of the local medical practitioners, public health and education authorities, child-welfare workers, and health visitors, under the chairmanship of the medical officer of health, to decide on the best means of setting on foot the adoption of diphtheria immunization, and he appealed to the meeting to initiate such a movement.

In the subsequent discussion, Dr. S. Monckton Copeman, F.R.S., referred to the successful use which had been made of diphtheria immunization in dealing with the outbreak at the Soldiers' Daughters' Home in Hampstead in 1922. Dr. F. E. Screse, medical officer of health to the borough of Hampstead, stated as his firm conviction that diphtheria immunization as a preventive measure was bound to come, and that the medical profession as a whole should be prepared to advise it to their patients and to help in its adoption.

OXFORD DIVISION.

The fourth meeting of the year of the Oxford Division was held in the Radcliffe Infirmary on May 25th. Dr. William Collier, sen., was in the chair, and forty members were present.

Treatment of Laryngeal Conditions.

Mr. V. E. Negus gave an address on some common affections of the larynx and their treatment, illustrating his remarks with diagrams. He said that metallic foreign bodies in the larynx should always be removed by direct vision. Vegetable foreign bodies set up acute tracheitis and bronchitis, and tracheotomy had first to be performed before their removal. Inflammation of the larynx of an acute type was part of a general acute catarrh of the upper air passages, with a symmetrical distribution, eliminating any difficulty in diagnosis. Doubt might arise in cases of chronic laryngitis associated with infection of the upper air passages, in mouth breathers, and in patients with septic tonsils, teeth, or sinuses. In these cases it was necessary to exclude tuberculosis and syphilis; a cure resulted from removal of the cause. In regard to specific infections, the treatment of the laryngitis resolved itself mainly into treatment of the general disease. Syphilis of the larynx, in the experience of the lecturer, was a rare disease. Tuberculosis of the larynx, while it might take the form of a secondary lupoid invasion from a focus elsewhere, or be part of an acute miliary process, was generally secondary to pulmonary disease. The onset was painless, and it was only when the condition was advanced that pain became a prominent symptom. The presence of pain had a great bearing on the prognosis. In the early stage the prognosis was good as long as the general condition was satisfactory. Complete silence was essential to successful treatment, and in men it was also necessary to advise against strong muscular effect, such as the forcible use of the arms, when it was known that the cords came together sharply. In the more advanced stage, when the

disease had spread outwards, the prognosis was much worse. For the pain on swallowing orthoform was the best remedy. Among new growths Mr. Negus mentioned papillomata, which, beginning in children aged about 10, tended to disappear. Following a low tracheotomy the warty growths should be picked off from time to time. Malignant growths were usually squamous-celled epitheliomata occurring nearly always in men over 60, involving as a rule the anterior extremity of one vocal cord, and causing a certain amount of hoarseness, without pain or loss of weight. If diagnosed early the condition could nearly always be treated successfully by operation. The different operations for various stages in new growth formation were shortly reviewed. Mr. Negus also briefly discussed various functional affections of the larynx and their causation.

Clinical Cases.

Dr. W. WOOD showed three cases of disorder of the central nervous system.

1. A man, aged 40, suffering from tabes dorsalis. The affection had spread to the anterior horn cells, with resulting wasting of the small muscles of the hands, as in progressive muscular atrophy.

2. A man, aged 32, with the Parkinsonian syndrome following encephalitis lethargica. In this case there had been an interval of over two years of apparent good health.

3. A man, aged 40, with well marked signs of disseminated sclerosis. This patient had been in the hospital twenty years previously with paraplegia and incontinence of urine, from which he recovered, and it was not till sixteen years later that difficulty in walking recurred.

Mr. HUGH WHITELOCKE showed a case of osteo-arthritis of the right hip in a man aged 56. He had a history of hemiplegia and an enlarged right testis of four years' duration. The reflexes were all brisk and the Wassermann reaction was negative. He had been sent to hospital with a diagnosis of femoral aneurysm. Two recent cases with similar hard swellings in Scarpa's triangle, and a similar provisional diagnosis, had proved to be (1) Charcot's disease of the hip; (2) diaphyseal aclasia affecting the femur.

Mr. W. W. WAGSTAFFE showed two cases.

The first was a case of diverticulitis in a man, aged 38, who was admitted with five days' history of abdominal pain and vomiting. The temperature was 100°, and the abdomen was resistant all over; there was no dullness and the bowels were regular. The condition appeared to be very obscure, and the patient was watched for more than three weeks, during which time he did not alter appreciably, except that tenderness became more marked and it was thought that a mass could be felt under the right rectus. Laparotomy showed that the mass was an inflammatory condition on the mesial border of the ascending colon. There were also diffuse adhesions in the neighbourhood of the liver and round the gall bladder. The appendix was normal. In view of the absence of any obstructive symptoms and of the man's weakened condition it was not considered advisable to try any short-circuiting operation or to attempt the excision of the tumour. Accordingly a rubber glove drain was put down to the mass and the abdomen was closed. The condition gradually subsided and one month later the man was practically convalescent.

The second patient was a man, aged 53, who was shown at a meeting of the Association on May 27th, 1925, as a case of typhlitis (JOURNAL, June 20th, 1925, p. 1127). At that time a laparotomy was performed for a twenty-four hours' history of acute pain in the right iliac fossa and vomiting. The appendix was found to be not affected, but the caecum was acutely inflamed. Subsequent to the operation, which merely consisted in making a rubber glove drain down to the inflamed caecum and removing a practically norma appendix, there was a considerable amount of distension and constipation, but this rapidly settled down and the patient went home after about a fortnight. He remained well and at work, with the exception of intercurrent illnesses not connected with this illness, until two days before admission on May 17th, 1927. He was then found to be suffering from acute abdominal symptoms suggesting obstruction, with marked visible peristalsis. Under treatment the symptoms subsided and the patient was due to leave the hospital. The condition, no doubt, was a flare-up of the old typhlitis accompanied by tenderness and pain over the mass in the caecum, in exactly the same way as previously. The patient was reported to have cavities in both lungs, a tuberculous ulcer of the tongue, and a positive Sigma reaction. In view of these conditions it was not proposed to perform any further operation for the relief of the typhlitis unless it became absolutely necessary.

Reports of Societies.

CAUSES OF THE ONSET OF LABOUR.

AT a meeting of the Royal Society of Medicine, Section of Obstetrics and Gynaecology, held on June 17th, with Dr. A. DONALD of Manchester in the chair, Dr. R. A. GIBBONS read a paper on "The causes of the onset of labour."

Dr. Gibbons stated that this subject had interested those who had devoted themselves to the study of obstetrics from the very earliest times. Hippocrates, more than two thousand years ago, considered that when the foetus was mature, hunger drove it to press its feet against the fundus uteri, thus gradually distending the os. This theory has held even down to Freidrich (1831), although Galen did know of the contractions of the uterus and their effect on the os uteri. The theories as to the cause of the onset of labour were so numerous that only the following would be considered.

Brown-Séquard (1858), supported later by Leopold, first advocated the theory that the loading of the blood with carbon dioxide gas would lead to uterine contractions. Although this has been supported to a greater or less extent by other workers, it was not until 1925 that Blumereich apparently definitely disproved this supposition. Naegeli believed that at the end of pregnancy there was degeneration of the amniotic membrane, which, becoming detached, acted as a foreign body in the uterine cavity. Others, such as Leopold, found that detachment of the amniotic membrane began as early as the fifth month of pregnancy. Similarly the placenta, when the seat of multiple infarcts, might act in a like manner in the production of uterine contractions. By some workers the biochemical relations of the mother and child have been considered as factors in the cause of the onset of labour, but the evidence was too conflicting to be of any value. The influence of the nervous system on the contraction of the uterine musculature was next to be considered. Although it had been believed at one time and another that nerve centres for the uterus might exist either in the medulla or the lumbar portion of the spinal cord, the experiments of Kruieger and Offergeld demonstrated that when the uterus was cut off from all connexion with the central nervous system labour set in at the usual time and progressed normally. Furthermore, Routh, among others, had shown that after destructive injuries to the lower part of the spinal cord labour might progress normally, although unaided by voluntary efforts. There was, however, ample evidence to show that the uterine muscle was abundantly supplied with nerves, being in intimate connexion with the sympathetic nervous system. An immense amount of work had been done as regards the composition of the maternal blood in pregnancy, and it was considered that there were no known changes in this blood which might account for the onset of labour.

Changes in the endocrine glands had been studied in animals during pregnancy, and it might be assumed that similar changes took place in the glands of the pregnant woman. The ovary had two endocrine secretions, one produced by the ovarian tissue and one which was the product of the corpus luteum. It was probable that in pregnancy the corpus luteum so dominated the ovarian metabolism as to inhibit the normal ovarian secretion. But towards the close of pregnancy, with the involution of the corpus luteum, there was again action by the true ovarian secretion. Recent work by Dixon and Marshall suggested that the ovarian secretion activated the pituitary gland, which in its turn produced uterine contractions, therefore having an important bearing on the onset of labour. The pituitary gland was believed by some to be an important factor in the termination of pregnancy, but up to the present time definite proof of this fact was lacking. Cybulsky had demonstrated that the suprarenal gland, through the action of its secretion on the sympathetic nervous system, maintained in a state of tonus the muscular tissues of the body. It would not, therefore, be unreasonable to associate hyperactivity of this gland with the onset of labour. Various workers had allocated internal secretions to the

uterus and placenta, but their work was not generally accepted. It was well known that labour frequently followed a very slight emotional disturbance. This was of interest when it was remembered that the emotional state could produce activity in the suprarenal glands, the possible relation of adrenaline to the termination of pregnancy having been already mentioned above. It was very difficult to produce conclusive evidence that the foetus might be the source of the material circulating in the maternal blood concerned with the onset of labour. The fact that inefficient attempts at labour took place at the fortieth week in an extrauterine pregnancy, when the foetus reached full term, must be regarded as an argument in favour of this. Moreover, experiments by Stirling and Lane-Claypon had demonstrated hypertrophy in the mammary glands of non-pregnant rabbits following the injection of foetal extracts. Finally it was quite evident, whatever might be the cause of the onset of labour, this cause must be due to some material circulating in the maternal blood, which either accumulated throughout the pregnancy or was suddenly poured into the blood stream. In concluding, Dr. Gibbons wished to remark that he had brought his paper before the society to demonstrate how profound was our ignorance of the causation of a process taking place somewhere or other every minute.

Reviews.

DIAGNOSIS IN HEART DISEASE.

SINCE the issue of the first edition of Dr. PRICE'S *Diseases of the Heart*[1] eight years ago, a considerable number of new observations relating to cardio-vascular disease have been published; of these the author has incorporated a judicious selection in his second volume. Amongst others, the new matter includes articles on anaesthesia and cardio-vascular affections, *x*-ray examination of the heart and aorta, quinidine therapy in auricular fibrillation, and on the surgical treatment of mitral stenosis and angina pectoris. The book is intended for the general practitioner, and the clinical point of view is kept steadily in mind throughout. Thus, though the electro-cardiograph is the most precise means available for the analysis of cardiac irregularities, Dr. Price describes these chiefly in terms of palpation, auscultation, and of venous and arterial tracings, electro-cardiography being dealt with apart in a well illustrated chapter. While it is true that the type of irregularity can in most instances be determined without reference to the electro-cardiogram, yet, for a proper understanding of the subject, it is questionable if the separation is entirely to the reader's advantage. Again, greater emphasis might have been laid on the use of the hands, eyes, and ears in the differential diagnosis of the irregularities; for example, little is said of the exercise test in this connexion. In dealing with the myocardium and the effects of valvular disease on the heart, the author's views are perhaps more orthodox than modern; thus the sequential dilatation and hypertrophy of the various chambers is described in the usual manner, and fatty infiltration and degeneration still hold their place. As a whole, however, the book is good, and Dr. Price has accomplished his avowed object of presenting concisely information of service in the diagnosis, prognosis, and treatment of diseases of the heart by modern methods.

THE BLOOD PLATELETS.

THE book on the physiology and pathology of the blood platelets,[2] by Dr. J. ROSKAM, is a modest but comprehensive review of a field which has long called for the attention of the critic. Its literature is scattered widely through physiology, biology, pathology, and immunology, and it can have been no easy task to assemble and discipline this material. The author wields a somewhat destructive pen, but contrives to save from the wreck enough to form a solid foundation upon which to build a reasoned experimental attack upon the problem.

The scope of the discussion is best indicated by a summary of the conclusions to which Dr. Roskam comes. Having decided that the proof of the "vitality" of the platelets is good, he finds that there is, at present, no strong evidence that they play any fundamental or essential part in the symptoms of anaphylactic shock or haemorrhagic purpura, in blood-clotting or the contraction of the clot, or in immunity phenomena. On the other hand, important morphological changes accompany clotting, and the platelets do undoubtedly accelerate clotting and the contraction of the clot, and do disappear from the blood stream during shock. This is held to be due to agglutination and entrainment in certain capillary areas. They will agglutinate bacteria as a result of surface phenomena analogous to the early stages of phagocytosis. Finally, extracts of platelets exhibit confusing effects upon blood pressure, which suggest that simultaneous vaso-dilatation of the arteries and constriction of the capillaries are involved.

All those who have become interested in these much disputed elements of the blood will welcome this review of the work and conclusions of the French school.

RADIOLOGY.

IN *X-Rays Past and Present*[3] Mr. V. E. PULLIN and Mr. W. J. WILTSHIRE of the research department, Woolwich, give a clear and well written account of the history, theory, nature, and practical uses of *x* rays. It is well balanced, and forms a useful introduction to the study of radiology. In the historical account of the application of *x* rays to medicine it makes clear the rapidity with which results of practical value were obtained. No attempt is made to deal exhaustively with diagnosis, and, very properly, little is said about treatment. In fact, the scientific aspects of radiology are the object of the work, and the medical details mentioned rather illustrate this than appear for their own sake. The importance of adequate protection is rightly insisted upon, as the commercial applications of *x* rays are extremely wide, and their use in industry will demand installations of special design, which will be handled by those who are neither experts nor medical men. The many and varied uses of *x* rays in industry—"from golf balls to aeroplanes, from chocolates to big guns, from the fitting of shoes to the detection of 'faked' oil paintings"—are well illustrated by skiagrams of flaws in casting, the presence of bullets in cartridges supposed to be blank, and the internal structure of German shells and ammunition. The concluding chapter brings out with light touches the responsibility of the solid British business man, whose inherent conservatism renders it a difficult task to get *x* rays used to the full advantage of industry.

Roentgen Interpretation: A Manual for Students and Practitioners,[4] by GEORGE W. HOLMES, assistant professor of roentgenology in the Harvard Medical School, and HOWARD E. RUGGLES, professor of roentgenology in the Medical School of the University of California, which is now in its third edition, is a guide to *x*-ray diagnosis and, being liberally illustrated by skiagrams, admirably fulfils its object. The authors wisely insist on a knowledge of pathology and on the importance of taking every available opportunity of correlating the skiagraphic appearances with the anatomical conditions, and, in the first chapter, deal with appearances which may erroneously be regarded to indicate disease. The consideration of bony and skeletal conditions, including the skull, occupies about half the work; of the gastro-intestinal tract and the chest each about one-sixth; and of the genito-urinary organs about a twelfth. Some of the skiagrams, such as that of a haemophilic elbow-joint with organizing blood-clot in the capsule, and of a patent ductus arteriosus, as indicated by the prominence of the curve of the pulmonary artery, are specially interesting. There are also skiagrams [illegible]

[4] *Roentgen Interpretation: A Manual for Students and Practitioners.* By George W. Holmes, M.D., and Howard E. Ruggles, M.D. Third edition, revised. London: Henry Kimpton. 1926. (Med. 8vo, pp. vii + 326; 226 figures. 21s. net.)

the use of lipiodol in bronchiectasis, but there are not any in connexion with the diagnosis of tumours of the spinal cord. Pyelography, and Evarts Graham's method of visualizing the gall bladder with tetraiodophenolphthalein, are clearly but briefly described, and it is pointed out that these procedures are not entirely devoid of danger to the patient. The last chapter deals with fluoroscopic technique, and its final paragraph points out that the possession of a fluoroscope does not make a roentgenologist, and that the subject cannot be mastered in a few weeks.

PUBLIC HEALTH IN CANADA.

THE progress of public health in Canada, and especially in the province of Ontario, is reflected in the second edition of Professor FITZGERALD'S *Introduction to Preventive Medicine*,[5] which at an interval of some five years follows the first, published in 1922 and reviewed in the JOURNAL of August 4th, 1923. The section on scarlet fever now contains an account of the test introduced by G. F. and G. H. Dick, and of the immunization and antitoxic therapy identified with their names. The section on tuberculosis has been amplified by a fuller discussion of incidence and modes of transmission. In his advice to the physician on the management of diphtheria the author recommends examination of the throat, repeated at least every twelve hours, pending the verdict of the bacteriologist. He adds, however, that "if there is reason to think that the case may be one of diphtheria, antitoxin should be given at once." Reference is made to the dramatic reduction in the prevalence of typhoid fever which, both in the United States and in Canada, has attended the purification of water supplies. The statement survives from the first edition that Defoe described the Black Death of 1348-49. It emerges that opposition to vaccination against smallpox is not unknown in Ontario. The author says that during the Toronto outbreak of 2,867 cases "a few misinformed and misguided individuals increased the difficulties of the situation by carrying on the usual vituperative and untruthful campaign against vaccination." One method of vaccination only is recommended, that of the linear incision, but the drill and the acupuncture methods are mentioned. The official English plan of scarification, with its prescribed areas of vesiculation, is passed over in silence.

The total bacterial count for certified milk is, in Ontario, required to be lower than in this country, but no standard for *B. coli* is laid down. A simplified arrangement of house pipes for drainage is current in North America. The schemes depicted in the book do not exhibit separate soil pipes and waste pipes. All sanitary fixtures, after trapping close up, join one common vertical stack, which passes direct to the drain. With regard to rural education in hygiene Lumsden is quoted as saying that "there was no optimism about teaching old farmers new hygienic tricks, but it was thought that the school children with instruction in hygiene might, upon becoming grown up, apply their hygienic knowledge."

The evolution of public health in England, the United States, and Canada is reviewed, the difficulties of smaller local authorities are recognized, and the relative values of the various activities of a public health department are appraised on a numerical basis. Professor Fitzgerald's book may be cordially recommended to the English reader. While necessarily dealing to some extent with the problems of a rapidly developing country, it treats the subject on broad lines, and never loses touch with the general principles by which sound public health policy must everywhere be guided.

APHORISMS.

THE Dean of St. Paul's, as our readers know, is a friend of medicine and science. *Wit and Wisdom of Dean Inge*[6] is a volume of selections made and arranged by Sir JAMES MARCHANT and prefaced by the Dean, who, in modestly criticizing his own writings, adds one more to the aphorisms to follow: "Originality, I fear, is too often only undetected and frequently unconscious plagiarism."

It is evidence of the broadmindedness of this fine classic and authority on Plotinus and on neo-Platonism that he considers science as an instrument of liberal education to have a far higher value than is usually conceded by humanists, and "the air which blows about scientific studies is like the air of a mountain top—thin, but pure and bracing." Wisdom he defines as "a just estimate of the relative value of things," the wisdom of the wise as "an uncommon degree of common sense," and the Utopian as "a poet who has gone astray." The letter of a schoolboy warned by a father, who fancied himself busy, not to be diffuse, is worth quoting for its terseness: "S.O.S., L.S.D., R.S.V.P."

As is well known to his readers, Dean INGE believes that any improvement in human nature is to be looked for in the infant science of eugenics.

NOTES ON BOOKS.

DR. J. FORD ANDERSON has published a little pamphlet of *Reminiscences of Lister*.[7] Dr. Ford Anderson first saw Lister in 1861, at an operation by Syme of Edinburgh on an aneurysm of the gluteal artery, but only got to know him well when he came to London in 1877. Dr. Anderson attributes to his Quaker upbringing Lister's seriousness in study and his spirit of love and desire to render good service to mankind. He found him a highly sensitive man, who exaggerated the opposition he met with from London surgeons. He had almost an obsession that his contemporaries were banded against him, though, in Dr. Anderson's opinion, almost every surgeon had accepted the principles by the time Lister came to London. Lister was a firm believer in the truth of his principles, and consequently fearless in operation. He was no self-seeker; and, in proof of his kindness, Dr. Anderson relates that, having a son at Winchester with an attack of diphtheria, and knowing that in those early days he could only get antitoxin at the Jenner Institute, which was closed, he hurried to Lister, the president of the institute, and told him of his difficulties. Lister came out on an inclement night in an open carriage, and obtained the antitoxin. It was only later that Dr. Anderson discovered that Lister had been confined to the house for three weeks with a bad catarrh.

Dr. L. BARD, in his book on the clinical forms of pulmonary tuberculosis,[8] recapitulates and discusses the system of classification that he first put forward in 1898. His main contention is that no classification of pulmonary tuberculosis is of any value unless it is dynamic. It is not enough to describe the localization of the lesion; it is essential to indicate its mode of development. Every type of tuberculosis, according to the author, evolves in its own way; hence if the type be correctly diagnosed the prognosis can be settled. In the classification he suggests pulmonary tuberculosis is divided into five groups—parenchymatous, interstitial, bronchial, post-pleuritic, and indeterminate—each of which is again subdivided. The parenchymatous group, for example, is divided into abortive and progressive forms; the progressive forms are again divided into caseous, fibro-caseous, and fibrous forms; and each of these is again subdivided into from three to eight classes. The classification rests partly on a clinical, partly on an anatomical, and partly on a pathological basis. It is not surprising that the author, when considering the objections that have been raised to it on account of its complexity, admits that it presents difficulties not easy to master. The great merit of Turban's classification is that it can be used with tolerable accuracy; it is generally possible by clinical and radiographical methods to determine the extent of the lesion. But by no means, other than making a microscopical examination of the lungs, is it possible to say whether a patient should have been placed in the (*d*) caseo-fibrous or the (*e*) fibro-caseous division of the (2) fibro-caseous types of the (B) progressive forms of the (I) parenchymatous class of pulmonary tuberculosis.

There is really very little to say about Dr. PIERRE PRUVOST'S book on tuberculosis of the lungs and of the serous membranes.[9] It is unconventional, direct, discriminative, and quite sound. The author chats in turn about diagnosis, treatment, and

prognosis, expressing his opinions with perfect confidence. He deals at length with artificial pneumothorax, and adds a few pages on the use of oleothorax. The section on tuberculosis of the serous membranes is limited chiefly to the pleura and peritoneum. We can truthfully recommend it to all who have charge of tuberculous patients.

Volume 51 of the *Transactions of the American Gynecological Society*[10] is edited by Dr. A. H. Curtis, and contains the address of the president, Dr. F. S. Newell, and numerous well illustrated papers dealing with gynaecological subjects. A general index of volumes 1 to 50, covering the years 1876 to 1925, has also been issued; it includes lists both of subjects and authors.

The empirical medicine of the palmist, if you are credulous, must be most satisfying: it is so simple. Mr. NOEL JAQUIN declares in his book *The Hand and Disease*[11] that when you have learnt the position of the mounts of Saturn and Apollo, observed the girdle of Venus, and wandered along the via lasciva, a little study of lines of fate, life, and mentality will enable you, not merely to state the disease from which the patient suffers, but to predict what awaits him in the future. Mr. Jaquin anxiously assures us that the names of ancient gods applied to knobs and lines must be regarded as mere labels, with no astrological significance. There seems, however, to be a significant appropriateness; since the girdle of Venus is usually present in those with marked sexual impulses, while the via lasciva is darkly indicated as suggestive of "some form of artificial stimulation of the nervous system being indulged in which can only lead to nervous exhaustion." According to this ingenuous author, the most interesting and important type of hand is the "cancerous"; unfortunately, it may easily be confused with the neurasthenic type! The lines are deep and thick, the finger-nails show a predisposition to rheumatism, and the lines on the outer edge of the hand indicate sluggishness of the bowel. Discretion in diagnosis is, however, so necessary that "unless you are *sure* remain silent." Emotional depression is sometimes caused by the "impingement" of a main nerve. A nerve that becomes impinged would seem to be like a water-pipe that is pinched—it cannot carry the normal supply of current. This, it is said, is usually due to displacement of a vertebra, and can be cured by eminent "spinologists." It appears, therefore, that palmistry and osteopathy dovetail into one another, and make a common appeal to the half-baked and the neurotic.

THE UNITED STATES ARMY MEDICAL REPORT.*

THE report of the Surgeon-General of the United States Army for 1926 refers to the fiscal year ending in June, 1926, but the main part of the report, dealing with the health statistics, is concerned with the twelve months of the year 1925. The mean strength of the United States Army for that year was 11,429 officers, and 111,467 white and 2,219 coloured troops; in addition to these there were 839 nurses, including reserve nurses on active duty and student nurses. The strength of the troops in stations of the United States was 98,343, in the Philippines 11,539, in Hawaii 14,164, in Panama 8,428, in China 934, and in Porto Rico 1,180, with a proportionate distribution of nurses. But in addition to these a large number of civilians, approximately 75,319, dependants of officers and men on the active and retired lists or employed in connexion with army services, came under the professional care and treatment of the army medical service.

The establishment of medical officers was 922, of dental officers 154, and of veterinary and medical administrative officers 125 and 71 respectively, all of whom are under the administration of the Army Medical Department. During the year under review, however, the medical corps had 61 officers below establishment, and only 73 per cent. were available for general duties, the remainder being employed in administrative work or as instructors and students in the various schools. In these circumstances the Surgeon-General emphasizes, as in the previous year when there was a similar deficiency in medical officers, the inadequacy of the medical personnel. The number of dental officers, although only four below establishment, was also considered inadequate for the extensive duties of dental prophylaxis and treatment which they are now called upon to perform. For the past twenty-five years the proportion of dentists has been 1 to every 1,000 troops. The Surgeon-General considers that the proportion should be doubled.

Medical Personnel.

The enlisted ranks of the medical services numbered 6,472 of an authorized establishment of 6,522. Other interesting statistics of medical personnel refer to the numbers enrolled in the reserve of officers of the medical, dental, veterinary, sanitary, and medical administrative corps. Reserve medical officers alone number 10,327; and the medical units, organized for mobilization in a national emergency, include 90 evacuation hospitals, 72 surgical hospitals, 24 hospital centres, 146 general hospitals, and 72 hospital trains. Many of these units will be obtained by taking over *en bloc* well established civil hospitals with their complete staffs. In addition to these there has been a great increase in the commissioned and enlisted medical personnel of the National Guard, the number of officers being 1,246 and of other ranks 9,853, as compared with 128 and 841 respectively in the previous year. They provide 16 service companies, 35 ambulance companies, 12 collecting companies, and 29 hospital companies. Another feature in this extensive reserve organization of medical services is what is called "procurement planning," or plans for industrial foresight in supplying materials for the medical department in an emergency. Valuable assistance in this respect has been rendered by several trade organizations and leading members of the industries concerned.

Incidence of Diseases.

The health of the army is stated never to have been better than in 1925, although the admissions for injuries had increased. Bronchitis and the respiratory group of diseases, as in the previous year, head the list of admissions with a rate of 177.77 per 1,000, the next highest rate being 52.55, for venereal diseases. Bronchitis alone accounted for 6,729 admissions, or more than double the number in the British Army. The admission rate for venereal diseases is the lowest on record, and a significant decline from rates, amounting to 100 and 200 per 1,000, in the years previous to the great war. Prophylactic measures are compulsory, and an officer or soldier who fails to use them is subject to trial by court martial. Prophylactic outfits are issued, and prophylactic treatment centres, with orderlies in attendance, are established in garrison stations. Further, there is a physical inspection monthly, and pay is stopped during days of inefficiency on account of venereal disease. As these diseases show by far the highest rates of constantly sick, the loss of pay must be considerable.

In view of the Federal Prohibition Law the extent to which alcoholism and drug addiction prevail is of interest. With the exception of the years 1918-19, when the admissions were insignificant, an admission rate for alcoholism in the neighbourhood of 8 per 1,000 shows little variation since 1916. Drug addiction, however, shows signs of declining. It is interesting to compare the admissions for alcoholism with those in the British Army. In 1925 the number for the United States Army was 1,084, practically the same as in 1924. In the British Army, of considerably greater strength, in the year 1925 it was *nil*. Malarial fevers have been the chief causes of admission in the British Army. In the United States Army they have been reduced to the low rate of 8.67 per 1,000 in 1925. Between 1902 and 1917 the admission rate for these diseases among white troops in the United States alone averaged 24.45 per 1,000, and in the years between the civil war and the Spanish-American war 271.50 per 1,000.

Mortality Figures.

The annual death rate from all causes, 3.77 per 1,000, was also the lowest recorded in the history of the United States Army. The death rate from diseases was only 1.94, the first time this rate has fallen below 2 per 1,000. The rate from injuries, on the other hand, has increased, and exceeded the deaths from disease. It was 1.99 per 1,000, as compared with 1.89 in 1924 and 1.90 in 1923. This rate has never previously been exceeded, except during years of battle casualties. Suicide heads the list of deaths from all causes, not only in 1925, but for several years past. Drowning comes next, then aeroplane accidents, followed by tuberculosis and automobile accidents. The prominent position of suicides in these statistics is noteworthy, as is also the fact that nervous disorders, although not occupying a high place in the admission rates, are the chief causes of invaliding.

These are only a few of many points of interest and valuable study in this voluminous and exhaustive report. It is amply provided with statistical charts, and concludes with tables of detailed statistics of admissions, deaths, invaliding, and inefficiency from individual diseases and injuries in the United States, in the several oversea commands, and among civilians and members of the nurse corps.

British Medical Journal.

SATURDAY, JUNE 25TH, 1927.

RADIUM IN UTERINE CANCER.

It is now five years since treatment by radium was introduced at University College Hospital, and in preparing his report for the year 1926 the registrar, Dr. A. E. B. Paul, has taken the opportunity of prefacing the account of the year's work with an analysis of the results of the previous five years' treatment. The report has special reference to carcinoma of the cervix uteri and menorrhagia.

Sixty-two cases of inoperable carcinoma of the cervix were treated, and 58 have been followed; of these only 6 are known to be alive, and 3 of them have recurrences. Those alive and well had treatment twenty-five, twenty-four, and twenty months before the date of the report; the duration since the first treatment of the three cases with recurrence is forty, seventeen, and sixteen months respectively. Fifty-two patients are dead, their average duration of life after treatment being fifteen months. In many of these cases the radium treatment rendered the patient more comfortable, especially as regards the lessening of the haemorrhage and the alleviation of pain. A cure in any sense was not to be expected with any degree of confidence, but the patients' lives were certainly made easier. In the last report it was stated that a new method had been employed in treating cases with infiltration of the broad ligaments—namely, implantation of radium needles after laparotomy. Three cases in which this procedure was adopted are recorded; two of the patients are alive and have no recurrence after twenty-one and sixteen months respectively; the third case is alive after fourteen months, but has extensive recurrence. Of the operable cases of carcinoma of the cervix, 7 out of 13 patients treated with radium are alive and have no recurrence after forty-three, forty, twenty-nine, twenty-four, twenty-two, twenty, and twelve months respectively; one patient is alive after forty-seven months, but has a recurrence. It would therefore appear that in operable cases, when for any reason operation is contraindicated, a fair number of cures for at least two years may be expected. Twenty-two cases of carcinoma of the cervix were treated with radium and also operated upon, a complete Wertheim's operation being performed in most; of these, 5 are alive and without recurrence after sixty-two, fifty-four, thirty, twenty-four, and twenty-one months respectively; 3 are alive after fifty-four, thirty-three, and eighteen months, but have recurrences. One of the above, it will be observed, is still free after five years. Of 18 cases of carcinoma of the body of the uterus treated with radium only or by radium and operation, 12 are dead, 3 are alive without recurrence, 1 is alive but has recurrence, 1 cannot be traced, and the other case was a four years' cure when last heard of.

With regard to non-malignant cases, the results of treatment by radium in menopausal haemorrhage are extremely good, only a few cases requiring a second dose. The usual dose given is 3,000 to 3,600 milligram hours of the salt, and the technique of plugging the cervical canal as well as the vagina is now the standard practice. The results of radium when used in cases of essential menorrhagia are stated to be also very encouraging, the dose used being about 1,000 milligram hours of the salt. Cases of fibromyoma of the uterus varied much as regards results, but out of 20 cases first treated over a year ago, 12 have shown good results as regards the cessation of haemorrhage, and 3 required further doses before this was attained.

With regard to the main part of the report, which deals with the work for the year 1926, the cases are conveniently classified, and each one is carefully and completely described. The report, sixty pages in length, shows evidences of great care in its preparation, and the registrar is to be congratulated on the completion of an excellent piece of work.

SEWAGE DISPOSAL.

No more profound change has occurred in the sanitary circumstances of this country than that from a conservancy to a water-borne system of excrement disposal. Its share in improving the health of the community may be difficult to disentangle from the many other factors which have also contributed, but no one can question the magnitude or the importance of this change upon the health, more especially of urbanized communities. Like all other improvements, however, it has brought its own tale of troubles, and the problems peculiar to the disposal of sewage have exercised the resources of the chemist, the engineer, the biologist, and the sanitarian for well over half a century. Progress in the solution of these problems has been slow, costly, and difficult; it has advanced in the teeth of ignorant prejudice and popular indifference, and the civic neglect in which they were reflected. But there has been progress in knowledge and in its application. Research has disclosed the manner of operation of the natural processes by which the desired ends were attained, and the enterprise of exemplary public authorities has furnished in a variety of forms the "plant" in which on a practical scale the natural purification of sewage has been developed.

The activated sludge process may be said to be the latest development of the prolonged attempts at sewage treatment which were the inevitable outcome of the widespread adoption of the water-borne, sewage-producing system. How far it has been successful and to what extent, by whom and with what results it has been adopted, may be read in Mr. Arthur Martin's recent book on this subject.[1] The process itself is essentially what may be described as a natural process. It is in the direct line of descent from the earliest, pre-human stages by which nature disposed of dead organic matter. When this has passed into solution or otherwise become physically incorporated with water, the changes such a liquid undergoes in its progress towards a pristine purity are identical throughout a wide variety of methods of disposal. The soil was always known as the great purifier. What the soil failed to accomplish the rivers completed, given time and opportunity. But with the advent of the industrial age these were lacking. Intensification of purifying processes became necessary as the soil sickened and the rivers became offensively polluted. The development of the biological sewage "filter" was merely an application, on an intensive scale, of the processes natural to soil purification of sewage. The humus, the essential agent in the oxidative changes known to be necessary in the process of purification, was cultivated on the coarser particles of the

[1] *The Activated Sludge Process.* By Arthur J. Martin, M.Inst.C.E., etc. London: Macdonald and Evans. 1927. (Roy. 8vo, pp. xiv + 415; 76 figures. 30s. net.)

biological "filter" under conditions in which the supply of atmospheric oxygen was greatly amplified. This has been the great advance in sewage purification in a multitude of applications during the last thirty years. But a growing recognition that the humus was the essential agent failed to suggest its utilization in the manner in which it operated in the rivers. Laborious attempts at oxidizing sewage directly by blowing air in a continuous stream of bubbles through the liquid led to the rediscovery, but not the recognition, of humus. Dr. Fowler, the originator of the method of treatment by "activated sludge," thus describes his earlier experiments: "In a series of preliminary experiments, samples of Manchester raw sewage, contained in bottles of 80 oz. capacity, were aerated until complete nitrification ensued, the aeration being effected by drawing air through the sewage by means of an ordinary filter pump. In the case of the first experiment, about five weeks' continuous aeration was required in order to obtain complete nitrification, as had been previously observed. At the end of this period the clear oxidized liquid was removed by decantation, and a further sample of raw sewage aerated in contact with the original deposited matter, until the sewage was again completely nitrified. This method of treatment was repeated a number of times with the retention in each case of the deposited solids. It was found that as the amount of the deposited matter increased, the time required for each succeeding oxidation gradually diminished until eventually it was possible completely to oxidize a fresh sample of crude sewage within twenty-four hours. For reference purposes, and failing a better term, the deposited solids resulting from the complete oxidation of sewage have been designated 'activated sludge.'"

Gradually the idea has dawned that this "activated sludge" is not sludge as ordinarily understood, but is a biological complex, a rich flora and fauna of micro-organisms mixed with organic matter in an advanced phase of dissolution. It rapidly sediments from the sewage with which it is mixed as a brown, earthy-smelling mixture containing about 99 per cent. of water. Mixed with sewage or sewage liquors, and in the presence of an ample oxygen supply, it rapidly separates the colloids and is associated in the oxidation of the organic matter present in the liquid. It is, in fact, humus in a free state. No longer anchored to the particles of soil or filtering medium, this free humus operates in the same manner as it does in rivers polluted to a degree insufficient to destroy its activity. Where pollution is so great as practically to de-aerate the water the aerobic life of the humus is destroyed, and the humus ceases to function as the beneficent agent it may be. Rediscovered in the process of blowing air through sewage, it is found to function satisfactorily, whatever the method of aeration of its habitat may be. Ardern and Lockett continued the work of Fowler in the extended air-blowing plants at Manchester. Haworth at Sheffield omitted the air-blowing, and propelled the mixture of sewage and free humus along shallow channels by means of paddles; relying thus on the continuous change of liquid at the air-sewage interface, he achieved like results. The conditions of natural purification to be observed in rivers were substituted for the similar conditions found to be associated with sewage purification on land or biological filters, and, while the results were equally satisfactory, their attainment was more economical in time, in area required, and in cost.

The treatment of sewage by free humus is now the subject of a variety of methods of application. Mr. Martin's book is an excellent guide to these various applications of the process. The data such as the chemist, the engineer, or sewage-works manager desires are well selected, clearly set out, and cover very completely the field of operations in which "activated sludge" has been chosen as the purifying agent.

THE F.R.C.S. ENGLAND AND CANADIAN CANDIDATES.

THE Council of the Royal College of Surgeons of England has had under consideration a proposal made a couple of years ago by the Canadian Medical Association expressing a desire that facilities should be arranged for Canadians, by post-graduate study and examination, to obtain the Fellowship of the Royal College of Surgeons. In the annual report of the Council of the Royal College of Surgeons for 1925 it was stated that the matter had been referred to a subcommittee to report on the desirability of substituting an examination in applied anatomy and physiology and in pathology for the present primary examination in anatomy and physiology. The subcommittee reported against this course, and the Council has recently resolved that no alteration should be made in the subjects of the primary examination for the Fellowship. The Council then decided that it was desirable to send examiners to the Dominions to conduct a primary examination for the Fellowship of the same standard as the examination in this country, and the secretary of the College, Mr. S. Forrest Cowell, and the Director of Examinations of the Conjoint Board, Mr. F. G. Hallett, were instructed, in consultation with the President, to enter into negotiations with the proper authorities in Canada regarding the conditions under which the arrangements for the examination could be made. It is hoped to send to Canada within a few days some suggestions, and it is thought that it may be possible to arrange for an examination to be held in Canada some time in the summer of 1928. The final examination for the Fellowship will continue to be held in this country. The subcommittee, before presenting its report to the Council, had a conference with the examiners in anatomy and physiology. The first question discussed was as to the most suitable time in the career of a candidate at which he should be required to pass the examination, and it was agreed that for various reasons it was essential that the examination should be open to third-year students as well as to men already qualified, and that therefore the examination should be framed in such a manner as to enable both classes of candidates to be treated on equal terms. The objection that it was difficult for a qualified man to go back to pass the same standard in anatomy and physiology as a third-year student was met by the expression of the opinion by the examiners that a general all-round knowledge of anatomy and physiology, such as the primary Fellowship requires, was essential if the candidate was to obtain the broad outlook necessary to enable him to reach a standard of attainment such as the Fellowship of the College should demand. On the subject of the high percentage of rejections, which was also discussed, several of the examiners who, as teachers, had a knowledge of the candidates, said that a good student who had passed well at the intermediate M.B. examination, and had worked for another six months, almost invariably succeeded in passing the primary Fellowship examination. The high percentage of rejections was largely due to the moderate and weak students, who, having successfully negotiated the M.B. examination with a bare pass, entered for the primary Fellowship examination on the offchance of passing. That high percentage was not evidence of an unsatisfactory form of examination, or of its uncertainty as a test of knowledge, but was due to three principal causes: first,

a failure to realize the high standard of all-round knowledge required; secondly, a system of cramming, instead of regular work in the dissecting room and physiological laboratory; and thirdly, a tendency to neglect the ordinary basic facts in favour of the latest theories and experiments. In recent years the questions both in anatomy and physiology showed a more decided bent towards medicine and surgery, but the examiners did not agree that the questions should be made still more medical and surgical, because that would involve a loss of a general all-round knowledge of human anatomy and physiology.

THE NEW DEATH CERTIFICATE.

In last week's JOURNAL (p. 1118) we gave a full account of the provisions of the Births and Deaths Registration Act, 1926, as far as they affect the duties and responsibilities of medical practitioners in relation to stillbirths, death certification, the viewing of the body of a deceased person, and the disposal of such bodies. The Act comes into force on July 1st, and we make no apology for once more directing the attention of practitioners (especially of general practitioners and of the medical officers of hospitals and institutions, on whom the duty of certifying the cause of death usually falls) to the requirements of the Act and of the Registrar-General in accordance therewith. Books of the new forms of certificate can now be obtained from the registrars of births and deaths, together with supplies of the official franked envelopes in which the certificates may be posted to the registrar. Attached to each actual certificate form is (1) a counterfoil, which should in all cases be filled up; and (2) a tear-off portion, constituting the notice that the certificate has been signed, which the practitioner is now legally required to give to the person liable to act as informant of the death for registration purposes. There is an important change as to the manner in which the particulars of the cause of death are henceforth to be stated. The nature and purpose of this change are described in the notes contained in each book of certificate forms, and in the article in last week's JOURNAL, to which we would again refer readers. It is essential that certifying practitioners should be as careful and accurate as possible in giving the information required, and an appeal is made for their co-operation in what is really an important piece of research work for the public advantage. Arrangements have been made for the publication of annual statistics regarding the extent to which the bodies of deceased persons are viewed by practitioners. It is desirable to encourage this practice in the case of a large proportion of deaths, and practitioners may be reminded that the registrar is directed to bring to the notice of the coroner cases in which the death certificate discloses the facts that the body has not been so viewed, and that the deceased person has not been seen by the certifying practitioner within a period of a fortnight before death.

THE ROMANCE OF ECONOMIC BOTANY.

THE romantic aspect of experiment and discovery in science was illustrated in a paper on the quest for economic plants read before the Royal Institution by Dr. A. W. Hill, director of the Royal Botanic Gardens, Kew, on April 16th. From prehistoric times economic plants were transported about the world, accidentally or otherwise; so that the staple crop of Gambia, the West African ground-nut, was probably introduced from South America by early travellers, and the West Indian sugar cane probably came from the East Indies. The attempt made in 1787, under the auspices of Sir Joseph Banks, first director of Kew, to introduce the bread-fruit from the Pacific Islands to the West Indies, was one of the earliest historical attempts at plant introduction, and was ultimately successful in 1793. The invention of Wardian cases, a kind of miniature greenhouse, by an examiner to the Society of Apothecaries in the nineteenth century, made possible the introduction of tea from China to India in 1848, of cinchona from the Andes through Kew to India, and of Para rubber from Brazil through Kew to the East. A relic of the German occupation of the Cameroons is still to be seen in a small experimental plot of tea at Busa, 3,000 feet above sea level. Dr. Hill described problems which arose in the cultivation of economic plants. Thus, the edible banana rarely sets seed; it is also highly susceptible to Panama disease. The problem is to cross a seed-bearing variety which is immune to the disease with an edible form such as the Gros Michel, and produce a seedless and resistant banana. But this banana must also have a thick skin in order to travel well; it must be of suitable size to invite purchasers; and it must be properly curved inwards on the bunch so as to be easily packed. The flavour, it appears, is a secondary consideration, as banana consumers are not usually connoisseurs. Dr. Hill described many of the pests against which the plant introducer has to fight, with the help of Kew and of the Imperial College of Agriculture in Trinidad; and showed that the romance of economic botany provides serious occupation for the plant physiologist, the pathologist, the agricultural chemist, and the geneticist.

THE REFORMED GOLD MINES.

ON July 1st next the Metal Grinding Industries (Silicosis) Scheme comes into force in Great Britain. It applies only to total disability due to silicosis or to silicosis accompanied by tuberculosis, or to the death of a workman from the same cause as certified by a medical referee. No doubt plenty of difficulties will crop up in the administration of this scheme, but we only allude to it now in contrast to the immensely greater scheme—mainly preventive—which has been so successfully carried through by the Medical Bureau of the Miners' Phthisis Board of South Africa under Dr. Watkins-Pitchford, its late chairman. A fascinating story of what has been done, how it has been done, and what still remains to be done is told by Dr. A. Mavrogordato, Research Fellow in Industrial Hygiene to the South African Institute for Medical Research.[1] In the gold mines the full-time services of nine medical examiners, a medical radiographer, a pathologist, and five photographers have set the engineers to work, with the result that the original type of the disease has changed from "a pure fibroid non-tuberculous type, the commonest and most characteristic form," as expressed in 1903 by the Transvaal Medical Society, to that which silicosis has apparently always assumed in this country. Thus Haldane, in his report on the health of Cornish miners in 1904, attributed great importance to tuberculous (or possibly other bacterial) infection. The change in type is from bulky lungs of the consistency of rubber, and characterized by right-sided heart failure, oedema, and dropsy, to lungs of ordinary size, without massive fibrous tissue, without failure of the heart, but still destroyed by superimposed infection. This change reflects the preventive measures adopted. At the commencement of the industry the prevalence of the disease was 30 per cent., owing to a dust content of the mine air which, at the beginning of the period, was 150 milligrams per cubic metre; by 1911 it was 20. By still further reduction in the dust content to 5 milligrams the prevalence was reduced to 3.3 per cent.; since 1920 the dust has gone down to about 2 milligrams per cubic metre. Even this great diminution is not

[1] *Contributions to the Study of Miners' Phthisis.* By A. Mavrogordato, M.A.Oxon., M.R.C.S., L.R.C.P. Publications of the South African Institute for Medical Research, Johannesburg. No. xix, vol. iii. (Cr. 4to, pp. 84; illustrated. 5s.)

considered wholly satisfactory, because a dust that can hardly disable *per se* may yet pave the way for a disabling infection. And even watering, which has done so much in allaying the dust, is not absolved from all responsibility, as such particles and bacilli as are still present in the air form the nuclei of droplets of spray constituting a more dangerous dust from the point of view of infection. In the early days men engaged in drilling who contracted the disease dropped out in two or three years, whereas now the average time in which simple silicosis is contracted has been lengthened to about ten years and a quarter. Moreover, it is only 3 per cent. of the total working miners, and only about 7 per cent. of those who have worked for ten years or longer, who annually become silicotic in any form. The conclusion reached in this section is that the engineer has about reached the limit of his capacity to improve conditions, and Mavrogordato raises the question whether medical intervention cannot carry the matter further by detecting and removing open tuberculous cases, among native labourers especially, and by raising resistance to tuberculosis by a suitable vaccine. The nodular structure of the silicotic lung is pictured by Mavrogordato as due to the incursion of hordes of the "large mononuclear phagocyte" (synonymous with the "macrophage" of Metchnikoff and the "dust-cell"), which are retained as specific cell traps; they aggregate together, with their content of dust and bacilli, into tubercles and pseudo-tubercles, eventually either themselves becoming fibrous tissue or stimulating its formation. The lung acts as a "specific filter," and becomes thus sown with the specific "cell traps." A difference between South African experience and that at home is that fibrosis of the lungs, at any rate in the pottery industry, has been diagnosed by medical examination at a period of employment earlier than that at which silicosis has been found by radiological examination in the same occupational groups. Among the microphotographs with which Mavrogordato illustrates his thesis are some showing the fibrosis taking place in the glomeruli and round the collecting tubules of the kidney. These have importance because the view that silica in a colloidal form has a specific poisonous action is now gaining ground.

ANTIVIVISECTION MEETINGS.

On the same day last week—Thursday, June 16th—three meetings were held by antivivisectionists. One was the annual meeting of the National Canine Defence League, presided over by Sir Robert Gower, M.P., who moved the second reading in the House of Commons of the Dogs' Protection Bill; he said that he had received a letter from Lord Dawson of Penn inquiring whether it would be congenial to the meeting if he were to attend and speak. The chairman said that he had assured Lord Dawson that he would receive a fair hearing. Lord Dawson began by saying that it might seem strange to the audience, but he was a great lover of dogs, and was the happy possessor of two dogs; one of them practically never left him, either at work or play. One of these dogs had lately become a victim of a serious disease, the "yellow disease," the mortality of which had been 70 per cent. Nowadays, owing to the discovery of a new remedy, the recoveries amounted to 70 per cent. The support for the experiments on dogs came, he said, from the medical profession, and not from one section of it. This statement produced an uproar, but when the chairman succeeded in procuring silence Lord Dawson observed that the scientific position was a matter for experts, and it was only on ethical grounds that opposition to vivisection could be raised by the general public. Dogs and other animals had one advantage over human beings, in that they had no power of anticipation, no consciousness of duty to others left behind, and no family or social ties. It was not so much the physical suffering that troubled human beings in illness, but the thought that near and dear ones might suffer. The performance of an experiment on an animal was similar to an operation on a human being; he had never seen any material difference. When Lord Dawson had concluded, the chairman declared that nothing Lord Dawson had said altered his conviction that vivisection was wrong. Nevertheless, the medical profession will admire Lord Dawson for spontaneously taking upon himself the disagreeable task of facing a hostile audience which did not wish to be convinced. Another antivivisection meeting was the annual meeting of the Council of the British Union for the Abolition of Vivisection; this was presided over by its president, Dr. Walter R. Hadwen, who said that the whole opposition met by antivivisectionists was based on the argument of the usefulness of vivisection. Their opponents, he said, declared that it was useful, and the general public would ask what were a few guinea-pigs or dogs or cats to the salvation of the human race. It was claimed that only medical men could know anything about the question; they knew less than anyone about it, and were too busy getting in the "bawbees" to bother about any question of that sort. Antivivisectionists declined to ask for anything short of the total abolition of that "iniquitous crime." Other speakers protested against experiments with poison gas on animals, and a resolution calling for the closure of the Porton establishment was carried. A resolution was also passed calling on the Government to refuse to comply with the petition of medical and scientific bodies that stray dogs should be handed over for experiment. The third meeting was the annual public meeting of the British Union for the Abolition of Vivisection; this lasted two hours, but uproar appears to have continued all the time, and the meeting broke up without transacting any business. It was said that the interrupters were medical and other students; if so we can only regret their action, for though the provocation has been great, no good could be expected to come of disorder, which should be left to the rowdy element of the antivivisection organizations. Yet another meeting had been held a day or two before; this was called by the Animal Defence and Antivivisection Society to protest against the memorandum recently issued by the Medical Research Council asking for an amendment of the present law to enable the police to hand over stray dogs for experiment. The Duchess of Hamilton was in the chair, and the chief speaker was Miss Lind-af-Hageby, who has been engaged in the agitation for a good many years. Dr. John Shaw also spoke, alleging that vivisection had undermined the morality of the medical profession. Other speakers indulged in similar foolish remarks. It can only be regretted that all these societies are kept alive by the donations and bequests of misguided persons who believe in the assertions made by the agents of the societies, and give or leave money for the perpetuance of the agitation. So far as we can gather, the antivivisectionists, taking them by and large, have now rather given up the public defence of their old contention that vivisection is useless, and are basing their opposition mainly on the ground that the practice in unethical and immoral.

THE PREVENTION OF RABIES.

RABIES is so essentially an international disease that it was almost inevitable that it should attract the attention of the Health Organization of the League of Nations. A conference was summoned in Paris during the last week in May, and a large number of scientists of all nationalities met at the Pasteur Institute. Three main aspects of the disease were considered—the nature of the virus, the results of treatment, and the prevention of disease in

animals. The modern concepts of French and other workers of the nature of the causal organism of rabies have previously been stated in these columns, and the commission confirmed the belief that the virus was filterable, but decided to leave as *sub judice* the organism described by Levaditi and Manoulian; nor did it decide whether the familiar Negri bodies were stages of the organism or cell degenerations. Opinion as to the efficiency of the Pasteur treatment by the original dried cord method and by the glycerinated cord method was unanimous. Similarly, it was considered that a virus killed or attenuated with carbolic acid or ether produced a satisfactory immunity, but it is recommended that such vaccines should receive more extensive trial on a larger scale, and that inquiries should be made into the plurality of strains, and into the rabicidal action of the serum of man and animals during and after immunization. While refusing to propose important changes in sanitary legislation, the commission, when considering the vaccination of animals, expressed the view that it was desirable to give dogs prophylactic vaccination against rabies, using a single inoculation of killed or attenuated virus (as we have previously described), and repeating this inoculation at yearly intervals. This would, of course, necessitate some form of administrative supervision and inspection of vaccinated dogs. Dogs, even if vaccinated, known to have been bitten by a rabid dog should be destroyed; but it was thought that if they were only suspected of having been bitten they might be vaccinated, provided they were isolated for six months. Prophylactic curative vaccination of cats is not recommended in any circumstances. Other animals should be vaccinated only in areas where the disease is particularly prevalent; and vaccination after the animal has been bitten is recommended. The conference expressed the view that the only measures which will completely eradicate rabies are the restriction of the liberty of the dog, unless muzzled, to the premises of its owner, and the destruction of the ownerless stray. It is recommended that these measures should be embodied in the legislation of the various countries. It was exactly by these measures, of course, that rabies was eradicated from Great Britain, and should it be accidentally reintroduced—a remote contingency so long as all animals entering are subjected to a six months' quarantine—their re-enforcement will be necessary. Other countries are less fortunately situated, but it is obvious that any action to eradicate the disease in Continental countries must be concerted, and for this purpose no better agent than the League of Nations could be selected to unify the actions taken by different countries. This new spirit augurs well for the future, and it may be that we are within sight of the complete disappearance of a most infectious and deadly disease.

GOVERNMENT LYMPH.

THE disappointment felt by many medical practitioners at the refusal of the Local Government Board, and afterwards the Ministry of Health, to allow them to obtain small-pox vaccine from the Government Lymph Establishment for use in private practice has not infrequently been expressed in our columns for a good many years past. The matter has now attracted some public attention, and in an article on the recent small-pox outbreak in Hendon and Hampstead the *Times* expressed the opinion that this refusal was inconsistent with the zeal now being shown to persuade people to protect themselves; the article suggested that the Ministry of Health should take steps to defeat propaganda against "impure lymph" by placing at the disposal of any registered medical practitioner lymph prepared under official authority. The article drew a letter from Dr. S. Monckton Copeman, who originated the methods used at the Government Lymph Establishment for preparing glycerinated lymph, officially adopted some thirty years ago by the Local Government Board for public vaccination work. He expressed the view that the existing state of affairs was unsatisfactory. The official reasons for restricting the supply of lymph to public vaccinators were that any other course would be unfair to private traders (some of whom, we may remind the Ministry, deal in foreign produce); that the cost of extension would be prohibitive; that official returns of the results of vaccination could not be demanded from private practitioners; and that it was impossible to provide sufficient staff for inspection of the work of vaccination. The last objection, Dr. Copeman pointed out, has disappeared, as official medical inspection has practically ceased. All the other objections would be met if a reasonable charge were made for supplies of lymph to medical men other than public vaccinators. The income from the increased output would probably more than cover the cost of any additional overhead charges, official returns would not be necessary, and no valid objection could be urged on behalf of institutions or individuals interested in the manufacture and sale of vaccine lymph. On the other hand, many private practitioners are no doubt quite well satisfied with things as they are; our only concern is to point out that the objections made to the general supply of Government lymph are not insurmountable.

THE WRITER AND THE EDITOR.

THE relations between the editor and the contributor were the subject of an interesting debate, opened by Sir Richard Gregory, editor of *Nature*, at a recent meeting of the Circle of Scientific, Technical, and Trade Journalists. Discussing the question whether an editor is justified in suggesting the character of a review or in altering it when sent in, Sir Richard Gregory condemned with proper emphasis the "trimming" of a review to suit any commercial or other consideration. For, as he well said, an editor's prime responsibility is to his readers, who trust him to provide interesting and accurate matter. Reviewers, he finds, and so do we, differ greatly in their understanding of what should be meant by a review. One kind of review he particularly dislikes is that which gives little more than a list of the chapters and a brief indication of what each chapter contains; such a conspectus he thinks more suited for the advertisement columns. To him a good review is one which makes the reader feel that the subject thus opened up is interesting and worth further exploration, whether by buying the book in question or in some other way. A thornier matter touched upon by Sir Richard Gregory was the extent to which an editor could legitimately alter the style of a contribution. It must be assumed, he said, that punctuation might be rectified, but some contributors very much objected even to slight changes in phraseology or style. Further, the editor had the right to decide the title of the article, and he should take a stand against any author who indulged in grammatical barbarisms and objectionable phrases. Among the common phrases Sir Richard found objectionable were "for instance" in place of "for example"; "it goes without saying" for "it need scarcely be said"; and "phenomenal" for "remarkable." Lack of uniformity in the use of capital letters was another matter to which he took exception, contending that it was an editorial fault to permit different systems to be followed according to the fancy of different contributors in the pages of the same journal. He spoke feelingly when he said how rarely a quotation was perfectly correct, though it was, of course, not always possible for an editor to verify every quotation and reference. He also touched on the question of how far an editor was justified in inserting cross-headings. Should this be left to the

contributor? Bearing in mind how few authors had more than the vaguest knowledge of type-setting and blocks, and how commonly in authors' proofs unnecessary corrections were made which involved the overrunning of a number of lines—a costly proceeding—he asked how far an editor was justified in disregarding such corrections. Sir Richard Gregory maintained that the sound working rule was that an editor can do what he likes with an unsigned article without the contributor having any right to object, though out of courtesy he might refer some points to the author; but he doubted whether in ordinary circumstances an editor had a similar right to make definite changes in a signed article. Upon this point there can, we think, be little room for doubt. Without consulting the author an editor has no such right in any ordinary circumstances, but occasionally it may be impolitic to enforce the rule too rigidly. One case that occurs to us is that of an obvious oversight in an article received from a distant part of the world, where the plan ordinarily followed by a printer—namely, to query the passage in the proof—would cause great delay owing to the length of the post. But if, as occasionally happens, an author within easy reach does not answer queries, what then? Another case is where at the last moment some passage is found upon which an action for libel might be based; if the author cannot be reached the question arises whether he would wish his communication withdrawn, or the peccant passage omitted or modified. If the first alternative is feasible the difficulty disappears, but in any event an editor must not print anything he suspects to be libellous. Finally, Sir Richard Gregory threw out the suggestion that it might be well to institute a school for technical authors, so that they should learn what was easily possible and what was quite impossible or unreasonable in the matter of correction after an article had been set up. This last suggestion was taken up during the discussion rather more seriously than might have been expected, and it was ultimately decided to refer the matter to a subcommittee of the Circle with a view to the preparation of short instructions, covering both the writing of scientific and technical articles and the correction of proofs.

FOREIGN BODIES IN BRONCHI AND OESOPHAGUS.

THE article by Mr. Tilley on bronchoscopy and oesophagoscopy with which this issue opens will help to increase the general interest in these methods, especially in respect of their value for the removal of foreign bodies. The whole subject, it may be remembered, was very fully discussed by Professor Chevalier Jackson of Philadelphia in a paper read to the Section of Laryngology at the Annual Meeting of the British Medical Association at Bath, published in our issue of October 17th, 1925 (p. 686). Before this (July 26th, 1924, p. 145) Mr. Waggett had reported a case in which a tooth-plate one and a half inches long and over three-quarters of an inch wide was successfully removed, and the patient made a rapid recovery. In Mr. Tilley's paper we have a number of accurate clinical histories compiled by a trustworthy observer; they will stand as a permanent record, and the paper is a contribution of which the value will remain unaltered by the passage of time. Several lessons are to be learnt from the cases related; these concern those first called to see such cases rather than those skilled in the use of endoscopic apparatus, and they are lessons which at the present day have been learnt only too frequently by the occurrence of a disaster. It is always unsafe to disregard a patient's complaint that he has either swallowed or inhaled a foreign body, for the immediate symptoms are often slight and transient, and the silent period soon follows. Removal of the foreign body at this stage is likely to be comparatively easy and safe, whereas delay in summoning efficient aid may allow severe complications to arise, which come on insidiously, and may compel the operator to face unnecessary dangers and even insuperable difficulties. Leaving aside technical questions, which can only be mastered by those having the opportunities for practice in this very special work, Mr. Tilley has chosen his case-histories to illustrate these and other points of a general but all-important character. From their very nature such cases arise in the most unexpected and disconcerting circumstances, yet, efficiently treated, they form a singularly satisfactory class, and it is well once again to call general attention to the value of the oesophagoscope, the bronchoscope, and the x rays in this striking manner, and to emphasize the conditions which allow them to be employed to the fullest advantage.

PULMONARY SCHISTOSIS.

THE effect of the dust created in their work on the health of slate quarrymen, splitters, and dressers has for many years been a moot point. Medical men practising in Wales, and quarry managers, are stated to have denied that slate dust injuriously affects the lungs. In France treatises have been written on *La Schistose* producing symptoms—emphysema, asthma, congestive attacks followed by pleurisy or pneumonia—suggestive of excessive inhalation of a not very injurious form of dust. Now Dr. T. W. Wade[1] of the Welsh Board of Health adduces evidence, mainly statistical, to incriminate the industry as the principal reason why, in the Gwyrfai rural district (which includes Snowdonia), the mortality rate from tuberculosis is higher than the general rate in the country, and higher in men than in women. The phthisis developing late in life in slate workers, he insists, supports the view now generally held that siliceous dust must be looked to as the cause of the phthisis. He finds, further, that the effect on the lungs of the quarrymen is not statistically so marked as on the hand trimmers, who work in sheds in which a thin haze of dust floats. On the other hand, the charts show that, in addition to this old-age mortality peak, a high mortality peak exists for both males and females in the young adult period of life. Dr. Wade is unable to explain this, although in two quinquennial periods—one before and the other after the war—the male and female rates from tuberculosis of the respiratory system were approximately double those of the rate for England and Wales. It seems a pity that other departments, such as the Home Office, with which the enforcement of preventive measures lie, were not associated with the inquiry from the first, as the present report contains no dust determinations, no results of the physical examination of the workers, or of x-ray photographs or *post-mortem* examinations. Dr. H. H. Thomas, petrographer of the Geological Survey, found that the most numerous particles were micaceous, and that in the sample submitted to him quartz came next. The majority of particles were very minute—about 1 micron—few reaching 5 microns. Chemical analysis showed that free silica was rarely present in a proportion of more than 60 per cent.

A NEUROLOGICAL JOINT MEETING.

A COMBINED meeting of the Section of Neurology of the Royal Society of Medicine and of the American Neurological Association will be held at the house of the society at the end of July. There will be a reception on the evening of Monday, July 25th, at 9 p.m., and on the following morning short papers will be read. On Wednesday, July 27th, at 9.30 a.m. a discussion on the cerebellum will be opened by Dr. F. Tilney, Dr. H. A. Riley, Dr. L. J. Pollock, Dr. L. E. Davis, Dr. A. J. Mussen, Dr. T. H. Weisenburg, and Dr. Harvey Cushing. On Thursday morning a discussion on sensory disorders in organic disease

[1] A report of an investigation into the alleged high mortality rate from tuberculosis of the respiratory system among slate quarrymen and slate workers in the Gwyrfai rural district. By T. W. Wade. Ministry of Health (Welsh Board of Health). 1927. Price 1s. net.

of the nervous system will be introduced by Professor J. S. B. Stopford, F.R.S., Dr. Wilfred Harris, Dr. Gordon Holmes, and Dr. S. A. Kinnier Wilson. In the afternoon short papers and demonstrations on pathological subjects will be given, and at 5 p.m. the Hughlings Jackson Lecture will be delivered by Dr. Charles L. Dana; in the evening there will be a banquet. Those who wish to read papers or show cases should communicate with Dr. W. J. Adie, joint honorary secretary of the Section of Neurology, at 1, Wimpole Street, London, W.1.

THE OXFORD OPHTHALMOLOGICAL CONGRESS.

THE Oxford Ophthalmological Congress will be held this year on July 7th and two following days. It will be opened by an address given by the Master, Mr. Philip H. Adams, B.M., F.R.C.S., on Thursday, July 7th, at 10 a.m.; the rest of that morning will be devoted to a discussion on the results of the operative treatment of glaucoma, to be opened by Dr. William H. Wilmer, ophthalmologist in chief to the Johns Hopkins Hospital, Baltimore. In the afternoon Professor F. Lagrange of Bordeaux will give an address on the best procedure to adopt for fistulization of the glaucomatous eye. A number of demonstrations will be given in the scientific and commercial museums in the afternoon, and the annual dinner will be held that evening in the Hall of Keble College, where the congress has its headquarters. On the morning of Friday, July 8th, Professor K. K. Lundsgaard of Copenhagen will give the Doyne Memorial Lecture, on the pneumococcus in connexion with ophthalmology. In the afternoon there will be a clinical meeting at the Oxford Eye Hospital. On the morning of the last day of the Congress (Saturday, July 9th) a series of addresses will be given in the Department of Human Anatomy. The full programme can be obtained from the Honorary Secretary, Mr. A. Bernard Cridland, F.R.C.S., Salisbury House, Wolverhampton.

SWISS CONFERENCE ON GOITRE.

WE have already announced that the Swiss Goitre Commission has arranged for a conference on goitre, to be held in Berne at the end of August; we have now received some further details. The conference will be opened in the aula of the University on the morning of August 24th by the president, who will give an address on the general distribution of goitre; this will be followed by a discussion on the pathological anatomy of endemic goitre, to be opened by Professor L. Aschoff of Freiburg, Professor C. Wegelin of Berne, and Dr. David Marine of New York. In the afternoon the pathologic physiology of the thyroid will be considered by Dr. Plummer of Rochester, U.S.A., Professor von Eiselsberg of Vienna, and Professor de Quervain of Berne. The whole of August 25th will be given to the question of the etiology and epidemiology of endemic goitre; the opening addresses will be contributed by Professor Bérard of Lyons, Lieut.-Colonel R. McCarrison, I.M.S., of the Pasteur Institute, Coonoor, India, Professor Galli-Valerio of Lausanne, and Dr. E. Bircher of Aarau. On August 26th, the last day of the conference, the prophylaxis of endemic goitre will be the subject of discussion, and in the afternoon a cinema film illustrating cretinism will be shown. Those members interested in the surgery of goitre may stay on till Saturday, August 27th, when Professor de Quervain will hold a demonstration in the surgical clinic. As will be seen, the conference will deal with no matter other than goitre. Further information can be obtained from the president, Dr. H. Carrière, Service fédéral de l'Hygiène Publique, Berne.

IT may be remembered that last autumn the Committee of Representatives of the Royal Society, the Royal Colleges of Surgeons of England and Ireland, and the Universities of Edinburgh and Glasgow, awarded the Lister Medal—founded to recognize distinguished contributions to surgical science—to Professor von Eiselsberg of Vienna, who will give an address at the Royal College of Surgeons of England at 5 p.m. on Thursday, July 7th. There will be a reception from 4 to 5 o'clock, and the specimens added to the museum during the year will be on view.

A FORTNIGHT ago we stated that Professor Pavlov underwent an operation on May 27th for gall stone; as he is nearly 78, and has been in indifferent health for several months, some apprehension was felt as to whether, in his debilitated state, he would be able to withstand the operation. We are glad to announce that, though after the operation he suffered from bronchitis for a time, this passed off, and a fortnight later he was judged to be on the high road to recovery. Dr. Horsley Gantt, writing to us on June 9th, said that he had seen Professor Pavlov on the previous day, when it was expected that he would be able to get about again within a week.

IT may be well to remind members who propose to attend the Annual Meeting of the British Medical Association in Edinburgh next month that the Hotels and Lodgings Committee has engaged all the available rooms in the city. Dr. Drever, the Scottish Medical Secretary, 6, Drumsheugh Gardens, Edinburgh, has undertaken the work of allocation, and members requiring rooms should communicate with him without delay. Very few single rooms are available in hotels, but there are some in boarding houses and hostels, and there are plenty of double rooms. Members proposing to attend the meeting who have made their own arrangements for accommodation are requested to notify Dr. Drever.

Nova et Vetera.

PARISH REGISTERS.

IT is generally supposed that the institution in the year 1538 by Thomas Cromwell of parochial registers, like Edward VI's foundation of grammar schools, was an attempt to fill a gap left by the abolition of the monasteries. Both suppositions have little foundation. The monasteries only concerned themselves with the registration of deaths of important persons, or at least of such as were wealthy enough to have left money to secure prayers for the repose of their souls; and the educational activities of the monks in the sixteenth century have been very greatly exaggerated. Had the enactment of Henry VIII's minister, and that made later under Elizabeth, been properly observed we should now have had in our possession a complete record of deaths, marriages, and births (or baptisms) for nearly four centuries. Unfortunately the duties thus thrust upon the clergy were unremunerated, and parishioners successfully resisted the imposition of registration fees. The bishops and consistories on whom, in 1597, Elizabeth placed the onus of keeping transcripts of the parish registers also in too many cases neglected their duties, and so it came about that by the year 1801, when the first census was taken, only 812 registers dating from 1538 were in existence in the 11,000 parishes of England. However zealous bishops, priests, and deacons may have been in the performance of their spiritual duties, they failed lamentably in the carrying out of their civil obligations. Even those poor 812 out of 11,000 registers are no longer all in existence, for a return made in 1834 showed that even that small number had decreased owing to the negligence of the clergy in the interval. Such as they were, the parish registers of England and Wales and the bills of mortality of the

City of London (BRITISH MEDICAL JOURNAL, October 8th, 1926, p. 645) formed the only basis on which estimates of the public health could be made for nearly three centuries, until the passing of the Acts for the civil registration of births, deaths, and marriages in 1836.

Luckily for the antiquarian and the social student there are extant a good many registers or their transcripts which, if not dating from 1538, nevertheless go back to the sixteenth century. Those for the parishes of Appledore and Eboney in East Kent begin in the year 1563-64 and are nearly perfect down to 1812. Fortunately for us these have fallen under the notice of that excellent antiquarian and student of medical history, Dr. William Cock of Appledore, who has just published a pamphlet containing his notes and reflections.[1] Dr. Cock's family have lived in Appledore for generations, and he has that sympathy for the land and its people which confers upon him the gift of making such dry bones live, so that his quotations and comments on the local records are full of interest, but of necessity many of them are connected with local topography and history only.

We are apt to regard the peaceful old villages of the English agricultural districts as having stood where they are since the Norman Conquest at least, the only changes being in the nature of rebuildings. These notes, however, and other local investigations of the same kind bring home to us the many sweeping changes that have occurred in the situation of roads and houses, as well as in population, in many an ancient village or "town" in the agricultural counties.

Appledore village is on the edge of Romney Marsh and much of the parish consists of marsh land where, until the introduction of quinine, ague was rife. Dr. Cock attributes the waves of poverty, which have left their marks in the register, to this scourge. There are just as many gnats as ever, and the marsh is no drier than it was; it seems therefore probable that to quinine is partly due the disappearance of malaria, although there must have been other factors at work here, as elsewhere, which are even yet not accurately known.

Appledore was, and is, too small to support a medical man, but it has at sundry times been the centre where one has lived and practised in the country around. Thus it is recorded in 1700: "Sep. 20. John Allen, a young man, our Surgeon and Physitian buried." Seventy years later one of his successors named William Durand, uncontrolled by any medical council or ethical committee, advertised himself in a Canterbury paper in the following terms:

> "Wm. Durand, Surgeon and Apothecary, begs leave to inform the Public that he has taken a Shop at Appledore, in Kent, where he proposes to practise Surgery and Physick; the experience which he has obtained in his Profession during a regular Apprenticeship in London, which he regularly served under a Gentleman of great practice, will, he presumes to flatter himself, recommend him to the Favor of the Inhabitants of this part of the Country; and those who think fit to call in his Assistance, may depend on his utmost Care and Assiduity in the Discharge of his Profession."

Such an advertisement was probably becoming unusual in 1770, and it is likely that the practitioners already established in the neighbourhood viewed it with disfavour. Durand seems to have established himself, however, and lived in Appledore twenty-two years, for his death is recorded in the register in October, 1792. Daniel Price, who published a quarto book on sheep farming in 1809, described himself as "Surgeon of Appledore." He seems to have been a practitioner of the Sangrado school, who lived (and died) up to his principles. He used to bleed himself much and often; he finally died from syncope caused by haemorrhage, and was found dead with his lancet in his hand. One wonders how many patients he had sent before him down the same road, by the same means.

We recommend all our readers who are interested in the short and simple annals of the poor—for it is of them that the notes mostly treat—to send for copies of this pamphlet and thus at once enable the Appledore village hall to be built, and get their money's worth in the antiquarian lore of Dr. Cock.

[1] *Notes from the Transcripts and Registers of Appledore, Kent.* By F. William Cock, M.D., F.S.A. 1927. Price 1s. Sold for the benefit of the Village Hall Fund.

RESEARCH AND THE COMMUNITY.

STEPHEN PAGET MEMORIAL LECTURE TO THE RESEARCH DEFENCE SOCIETY.

AT the annual meeting of the Research Defence Society on June 21st the first Stephen Paget Memorial Lecture was delivered by Professor JULIAN S. HUXLEY, M.A., who took for his subject "Research and the community." Lord LAMINGTON, the President of the Society, and afterwards Viscount KNUTSFORD occupied the chair.

Professor Huxley passed rapidly over research in physics and chemistry, and devoted himself to the biological aspects, taking as his first example the value of research in agriculture. He said that as agriculture extended it brought with it two fundamental difficulties. With an increase of the density of a crop in a given area it became much easier for enemies of the crop to multiply and spread. The second difficulty was due to the increase of travel and transport facilities, which brought animals and plants into new areas where they were freed from the normal checks to their multiplication, and accordingly did damage. Dr. Tillyard, the eminent entomologist of New Zealand, who visited this country last year, told him that the introduction of the common blackberry into New Zealand had led to the growth of nothing less than jungles of impassable thicket. Such introductions were often made with the best intentions, but because the subject had not been sufficiently studied the consequences were sometimes unexpected and serious. The best way of coping with plants and animals in new situations might be to introduce the natural parasites. Without research on an intensive and extensive scale in these fields a great deal of agriculture—especially tropical—would become impossible. Institutes of applied biology were needed to study the whole relation between animals and their environment. Proposals were afoot to exterminate squirrels in the New Forest and pelicans on the American coast because of the damage they did, but any interference of this kind should only be taken as the result of careful research, lest it made matters worse. The phenomena attending plagues of rodents were beginning to be understood; apparently some factor connected with the weather allowed the animals to work up to a maximum of density, and then epidemics occurred which nearly wiped them out, but then the cycle began again. Another value of research in agriculture was from the point of view of breeding. Mendelism was the general law, and theoretically at least, with knowledge and patience, it was possible to build up animals and plants more or less to order, since their hereditary constitution was composed of a great number of independent units which could be shuffled and re-combined by selective mating.

Pure medicine ought to have regard to the broader aspects of biology, especially in connexion with the question of heredity. It had been found by the selective breeding of mice that strains might be obtained much more resistant or much less resistant than usual to cancer, and the same might hold good in the human species, not only with regard to cancer, but to other diseases. A knowledge of heredity was of first-class importance to medicine. Heredity and education were complementary in building up the community. Practically every great nation was changing its hereditary make-up, the composition of its racial stock. Wholly new characters or different combinations of old characters were appearing. Research, even to the extent of national stocktaking on a large scale, was needed in racial and social hygiene. Remarkable effects, which might or might not be biologically or socially desirable, were being produced through the crossing of races. Certain races under the British and other flags were actually dying out, and it seemed to be agreed by investigators that this was happening to some of the Melanesian races through psychological causes, because they had not the will to live or reproduce. An imperial bureau of anthropology was just as clearly needed as the imperial bureaux of entomology and agriculture recently established.

Coming finally to medical aspects of research, Professor Huxley mentioned that the expectation of life was now nearly double what it was in the early times of the Roman

Empire. All the discoveries, most of them recent, which had led to this prolongation of life as well as to diminution of suffering had been made possible through the methods of science—that is, observation and experiment, the two alternating, one incomplete without the other, but experiment always the final arbiter. Experiments could be made in various ways, in test-tubes in the laboratory, on animals, or on human beings, and it did not matter from the point of view of advancing knowledge in what way they were made. In the discovery of chloroform the experiments were first made on man, and various details afterwards worked out on animals. In regard to antisepsis and asepsis, he read Lister's published letter written in 1875, in reply to one from Queen Victoria's secretary, setting forth his experience of the value of animal experiment. *Pasteur's work, which had been of enormous benefit both* to human beings and to animals, was only made possible by research upon the latter. He mentioned also the proved value of vaccination against small-pox, the working out of the Schick test in diphtheria, and the discovery of insulin. Just at the time that insulin was made public a young colleague of his own, with the promise of a brilliant career, had to relinquish all hope of it on account of diabetes; within six months he was preparing to take up his work again. In the work on yellow fever the final experiments were done on human volunteers. It was observation and experiment which was showing how to get rid of sleeping sickness, malaria, and hookworm disease. The spread of malaria was one of the contributory causes of the downfall of Greece and Rome, and disease was the most serious single factor with which our empire in India was menaced. Knowledge and research were the conditions under which the complex civilization of our wide and heterogeneous empire was maintained. Without knowledge there could be no control. It was right to demand that all the avenues to knowledge should be open, for it was never known along which avenue new knowledge would come. Among other instances he mentioned the Schafer method of artificial respiration, which was the result of experiment by that eminent physiologist on half a dozen dogs. Much had been done for animals themselves as the result of animal experiment; it was enough to mention rabies, anthrax, and glanders, diseases which had also a human background. The opponents of the Research Defence Society had every right to insist on adequate supervision of experiment, but he believed that Government inspection was efficient, and that in fact no abuses had been proved. It was impossible to think that the problem of cancer would be elucidated or the work on the virus of sleepy sickness completed without further experiment. The Research Defence Society seemed to stand in the public eye for a body which existed to resist definite attacks made upon research on animals; that was important, but it had a wider function: it had to fight against apathy, ignorance, and bureaucracy and red tape, and no less against the exploitation of the results of research—gained with great labour and difficulty by scientific men,—for base ends.

At the close of the lecture Miss LIND-AF-HAGEBY, of the British Union for the Abolition of Vivisection, asked permission to put certain questions to Professor Huxley. The questions she wanted to ask were: Did the Research Defence Society recognize any ethical restraint on research? Did it deny that great pain and suffering were caused to animals in British laboratories? And if it denied that such pain and suffering were caused, would it exert itself to secure the opening of the laboratories to inspection by accredited representatives of humane societies?

Lord KNUTSFORD from the chair said that these were scarcely questions arising out of the lecture. For his own part he thought there ought to be as little pain as possible inflicted in vivisection, that every possible step ought to be taken to avoid pain, and that the laboratories should be properly inspected. But he also pointed out that any pain inflicted by experiment was small compared with the pain involved in the preparation of animals for food. He then proposed a vote of thanks to Professor Huxley, and asked Miss Lind-af-Hageby if she would be good enough to second it, which, amid laughter, she did.

Sir DAVID FERRIER presented the treasurer's report on the work of the society, which, he said, thanks mainly to a generous legacy left by the late Dr. John Hall, was now relatively well off. The report of the committee expressed thanks to the British Medical Association for so successfully organizing the conference on animal experimentation on April 4th last. During the year the membership of the society had been increased by about eighty members. The new vice-presidents welcomed were Lord Meston, Sir Theodore A. Cook, Dr. Alfred Cox (Medical Secretary of the British Medical Association), Lieut.-Colonel F. E. Fremantle, M.P., Sir Dawson Williams (editor of the *British Medical Journal*), and Sir Squire Sprigge (editor of the *Lancet*). The new members of the committee were Professor C. Lovatt Evans and Dr. F. W. Goodbody.

Canada.

[FROM OUR SPECIAL CORRESPONDENT.]

PROVISION FOR MENTALLY DEFICIENT.

THE care of the mentally deficient in Canada generally has been receiving a considerable amount of attention. A Royal Commission was appointed to investigate conditions in Nova Scotia, with the assistance of the Canadian National Committee for Mental Hygiene. Recommendations have been made *inter alia* for the appointment of a provincial psychiatrist, the establishment of psychiatric clinics, and the erection of a provincial training school for mentally deficient children, and legislation has been introduced for the carrying out of these recommendations. In this connexion the report of the provincial health officer for Nova Scotia is of interest, since it shows that the state of some of the local asylums is far from satisfactory. An attempt, however, is now being made in the penal institutions to study age in relation to recidivism. It is pointed out that "the moral regeneration of an individual without an accurate record concerning his antecedents cannot be rationally attempted," and attention is called to the present system, which has little tendency to prevent recidivism. More rational methods in dealing with offenders against the law are advised. In New Brunswick a mental hygiene council has been organized, and steps have been taken to present to the Provincial Government various aspects of the problem, including the need for special efforts to provide proper institutional care for the feeble-minded.

The Verdun Protestant Hospital in Montreal shows an ever-increasing list of incurable cases, and there is urgent need for more equipment and buildings. There will be some relief when the new wing at Bordeaux becomes available for the dangerously insane, who will be concentrated there from the various institutions of the province; but with the rapid growth of Montreal (estimated at 50,000 per annum) the Verdun institution is in urgent need of enlargement.

In Manitoba the provincial psychiatrist is undertaking a survey of school children in the province three years or more below standard in school grades, or who present other signs of mental deficiency. In the city of Winnipeg the work is being carried out in conjunction with the school medical officers and the outdoor clinic of the Psychopathic Hospital. This report is expected to provide guidance both for the Government and school authorities.

CHARGES OF MALPRAXIS.

Two cases of medico-legal interest have recently been reported in Manitoba. The first was an instance of death of a child 4 years old whilst under chloroform for a minor operation. The operator, who gave the anaesthetic himself, was charged with manslaughter. Expert evidence was adduced to show that it is sometimes impossible to tell whether a child is unfit for anaesthesia or not, and that chloroform was still a recognized anaesthetic in spite of the more general use of ether. Some criticism, however, was made of the fact that absorbent cotton-wool was used on which to drop the anaesthetic, instead of gauze, although the physician had been accustomed to the use of wool for over thirty years. He was acquitted.

In the second case a physician was prosecuted by the

parents of a child who had died of asphyxia neonatorum soon after birth. The doctor had arrived at the house about thirty minutes after being sent for, but had been refused admittance because the child was born before he came. In giving their verdict the jury fixed no blame on the parents, but rebuked the physician for not having forced his way into the house against the will of the parents and grandmother!

Campaign for Montreal Hospitals.

A five-day campaign was conducted in the city of Montreal for funds in aid of the two leading English general hospitals—the Montreal General and the Royal Victoria—as also of the Royal Victoria Maternity Pavilion. The financial conditions of these institutions had reached a stage at which a serious effort was necessary to pay off deficits and to assure them of future support. The objective aimed at was four million dollars, but at the end of the campaign it was announced that this amount had been exceeded by 735,000 dollars, and, as several more subscriptions came in later, the total will probably be close on five million. This gratifying result was due largely to the extraordinary enthusiasm and vigour of a group of leading business men; while the response came from the public generally, it was the large corporations whose contributions made the fund so rapidly and completely successful.

England and Wales.

St. Thomas's Hospital Medical School: Distribution of Prizes.

The Duke of Connaught, President of St. Thomas's Hospital, visited the medical school on Tuesday, June 21st, for the purpose of distributing the prizes. His Royal Highness was met by Sir Arthur Stanley (treasurer) and Sir Cuthbert Wallace (dean), and proceeded to the Central Hall, where he inspected a guard of honour furnished by the Medical Unit of the University of London O.T.C., after which he unveiled the memorial erected to those of the hospital who fell in the great war. This memorial, placed at the end of the Central Hall, is a large carved oak panel bearing the names of one nurse, seventy-four students, and nine employees, the actual war memorial of the hospital being St. Thomas's House, the students' residential club recently opened in Lambeth Palace Road, of which an account appeared in our issue of April 30th (p. 808). The Dean prefaced his report on the year's work by referring to the sad loss the school had suffered in the death of Mr. J. T. Adams and Mr. Billingshurst. As regards the medical school, the number of students was greater than it had been since 1921, while the school had received its share of academic honours and maintained a high average of excellence. In sport things had not gone quite as well as last year, but it was not possible to win everything every year! He hoped on the next occasion to be able to report the opening of the new students' laboratories. The Duke of Connaught, having presented the various scholarship prizes and medals, was invited by Sir George Makins to present to Mr. Chisholm Williams, F.R.C.S. (a former student of the school), the bronze medallion of the Carnegie Hero Fund, together with a cheque representing the first instalment of a pension awarded him by the trustees of the fund in recognition of his services to radiology. Mr. Williams and the late Dr. Barry Blacker had been pioneers in the investigation of the clinical uses of x rays, both for diagnostic or therapeutic purposes, and both operators had suffered, Blacker being probably the first man to die as a result of the action of the rays. While Mr. Williams had suffered less severely, he had, nevertheless, been so disabled that he was unable to practise. X rays had claimed many victims, but the misfortunes of the pioneers had led to more adequate measures being devised for their protection. Mr. Williams was heartily cheered as he received the award from the Duke of Connaught, who said it gave him particular pleasure to make that presentation. They all admired what Mr. Williams had done, and regretted that he should have suffered. It had also been a pleasure to him to distribute the prizes and, by attending the hospital, give some indication of the great interest he took in everything connected with it. It was gratifying to note that the numbers in the school were so large and that St. Thomas's House was being found useful. His Royal Highness, in congratulating those who had won at sports, said physical exercise was most valuable because it went a long way towards not only making a man healthy, but enabling him to "play the game." He had had the honour of being the president of the hospital for a number of years, and as time went on his interest and pride in the great work and glorious traditions of St. Thomas's increased. Mr. Boyson (senior almoner) proposed a vote of thanks to the Duke, and in seconding this Dr. A. E. Russell (senior physician) expressed the hope that the happy association between the hospital and members of the Royal Family would continue in the centuries to come as it had existed in those that had passed. His Royal Highness, accompanied by the treasurer, members of the Grand Committee, and the staff, then attended the Nightingale Garden Party.

Treatment of Rheumatic Children in Birmingham.

We learn from Dr. H. H. Sampson, chairman of the Medical Board, that the Children's Hospital, Birmingham, has undertaken the medical supervision of the rheumatic children in Birmingham in co-operation with the school medical service. An office has been established at the hospital, and the almoner is responsible for the after-care work and for arranging the periodical examination of these children. A printed paper of instructions on the care of their children is given to the parents. There is no special rheumatism or cardiac clinic, but the cases are distributed between all the physicians of the hospital. Beds are provided in the hospital for children in the acute phase of the disease; when that has passed they are transferred to Moseley Hall Convalescent Hospital (a continuation hospital of the Children's Hospital), there to await admission to Baskerville, a resident hospital school under the control of the Birmingham Education Committee. By this arrangement a certain number of children are provided with prolonged institutional care covering a period of twelve months.

National Association for the Prevention of Tuberculosis.

The thirteenth annual conference of the National Association for the Prevention of Tuberculosis will be held in London from June 30th to July 2nd; it will take place in the Great Hall of the British Medical Association's house, and will be opened at 10.30 a.m. on Thursday, June 30th, by Mr. Neville Chamberlain, Minister of Health. An address will then be given by Sir John Robertson, C.M.G., medical officer of health for Birmingham and professor of public health in the University of that city; his subject will be the relative value of present lines of attack of tuberculosis. In the afternoon a discussion on housing, with special reference to home conditions, will be opened by Dr. H. R. Kenwood, C.M.G., Emeritus Chadwick Professor of Hygiene in the University of London, who will be followed by Sir Oscar Warburg (London County Council), Captain R. L. Reiss (Garden Cities and Town Planning Association), and Sir William Younger, Bt. (member of the Royal Commission on Housing for Scotland). In the evening the annual meeting and reception will be held, when the Marchioness of Titchfield will speak on the future campaign of the association. On the second day (Friday, July 1st) a discussion on housing in relation to industrial conditions will be opened by Professor Edgar L. Collis, M.D. (University of Wales), and Sir Thomas Oliver, M.D. (professor of medicine, University of Durham). The afternoon of that day and the whole of the last day will be devoted to visits to the Preston Hall Industrial Settlement, Maidstone, and the Burrow Hill Colony, Frimley, and also to inspections of housing schemes in Hammersmith, and of the Welwyn and Letchworth Garden Cities.

Welsh National Medical School.

When last we dealt with the controversy which has been going on about the status of the Welsh National Medical School it was stated that negotiations were to be continued

between the University and the College, and that a further report was to be made to the July meeting of the University Court. Last week a conference was held at Cardiff between representatives of the College and of the University, when a friendly discussion took place, but no final decision was reached. A special subcommittee, representative of both sides, was, however, appointed to continue negotiations and present a report to another meeting, which is to be held as early as possible.

BRISTOL ISOLATION HOSPITAL.

The new buildings added to the Bristol Isolation Hospital at Ham Green were opened on June 16th by the Lord Mayor. There had, he said, been great progress during the last forty years in the provision made for persons suffering from infectious diseases. Before 1892 patients who could not be treated in their own homes were removed to two wooden huts, providing twelve beds. In that year a hospital was built at Novers Hill; though some thought its erection was unnecessary its value was speedily demonstrated. Then the Ham Green estate was purchased, and by the use made of it both for zymotic diseases and for tuberculosis the position in the city had been revolutionized. The chairman of the health committee said that the treatment of infectious diseases had been so much improved that the average stay in hospital was now shorter. It was tantamount to an increase in the number of beds, but it had been necessary to make provision for tuberculosis, and the 136 beds for the treatment of that disease were practically always full. Since 1919 the size of the estate at Ham Green had been increased from 92 acres to 330, so that it was now possible to supply all the water needed by the institution, to complete the milk supply, to provide nearly all the meat required, as well as the fresh vegetables. The extensions give the isolation hospital an additional 56 beds, bringing the total available to 190 for a population of 383,000. The principal new building is a pavilion containing four large and airy wards, the south wing being devoted to single-bed wards. A nurses' duty room and other essential accommodation is provided, and covered verandahs have been built on the south side for use in suitable weather. A new administration block has also been erected on a piece of ground facing the main road, with suitable accommodation for the staff. The cost of the scheme amounts to £36,029.

PAY BEDS IN LONDON VOLUNTARY HOSPITALS.

The special committee appointed by the Prince of Wales, President of King Edward's Hospital Fund for London, to inquire into the question of pay beds at voluntary hospitals, has begun to receive evidence. The members of the committee are Viscount Hambleden (chairman), Sir John Rose Bradford, Sir Bernard Mallet, Mr. V. Warren Low, and Professor Winifred Cullis. All communications should be addressed to the Secretary, King Edward's Hospital Fund for London, G.P.O. Box 465A, 7, Walbrook, E.C.4.

TRAFFIC FATALITIES IN LONDON.

In a recent report the Commissioner of Police for the Metropolis has noted that traffic fatalities in London during 1926 were slightly over 1,000. At an inquest on June 9th, Dr. F. J. Waldo said that it was thought that the number of motor vehicles on the road would be doubled during the next four years. Dr. Waldo appeared to think—probably correctly—that this would increase the number of deaths from accident, though not of necessity proportionately to the increase in motor vehicles. He pointed out that under the Coroners (Amendment) Act, 1926, the cost of inquests would be doubled. It would be illegal to sit without a jury in all road and air accidents. Moreover, Dr. Waldo made it a rule to order *post-mortem* examination in all road accidents, in view of possible claims for compensation. The average cost of an inquest in London at present was £5. At present the number of ambulance stations in London is thirteen. He thought others should be established.

CENTRAL MIDWIVES BOARD.

The Central Midwives Board for England and Wales held a penal session, followed by an ordinary monthly meeting, on June 2nd, when Sir Francis Champneys presided. The standing committee dealt with a further letter from the county medical officer of health for Durham (see BRITISH MEDICAL JOURNAL, May 21st, p. 934) respecting the resolutions of the Board at its last meeting in connexion with the question of the suspension and disinfection of midwives attending infectious cases. The medical officer of health asked for further information, and the Board agreed to reply:

1. That under rule F.1 a midwife must be suspended from practice when necessary for preventing the spread of infection and that, in the Board's opinion, the local supervising authority, being the body which is conversant with the facts of each particular case, is the proper body to decide when suspension is necessary.
2. That under Rule E.6 a midwife liable to be a source of infection cannot attend another maternity patient unless she has been disinfected to the satisfaction of the local supervising authority (unless the local supervising authority relieves her from that obligation), and that, in the opinion of the Board, the local supervising authority is the proper body to prescribe the manner in which it shall be satisfied that adequate disinfection has taken place.
3. That the spread of infection should not be risked merely because midwives may suffer through suspension from practice. The local supervising authority should compensate any midwives who suffer through such suspension.

In reply to Dr. Statham of the Royal Infirmary, Bristol, on the subject of vaginal examinations, it was agreed to inform Dr. Statham:

That the Board considers that the question of vaginal examinations has two aspects, (*a*) that of practice, (*b*) that of training. It agrees that as regards (*a*) unnecessary vaginal examinations are to be avoided and that this should be embodied in teaching, but as regards (*b*) it is not safe that those who undertake the conduct of confinements should be unfamiliar with the method, or deprived of the knowledge which in many cases can only be gained by internal examinations. The progress of a labour can only be observed by the changing conditions ascertained by more than one examination. The Board notes that in the extern department vaginal examinations are regularly practised.

The honorary secretary of the Wiltshire Branch of the British Medical Association had forwarded the following resolution;

That this meeting approves of ante-natal examination, and is anxious that any movement to encourage it should be supported in every way, but is of opinion that more harm than good will be done if an attempt is made to carry out the work in the manner suggested by the form issued by the Central Midwives Board for use by midwives.

A copy of a form approved by the Medical Advisory Committee of the Branch, which it considers sufficient for the purpose, was enclosed. It was agreed to reply:

That in the opinion of the Board the training prescribed by the Board's rules will give midwives the knowledge necessary to keep the notes of their ante-natal visits which are indicated in the form approved by the Board. The Board appreciates the fact that there are in practice some midwives who may not at present be able to keep all the notes prescribed, but it is hoped that any such midwives will receive instruction in the matters in regard to which at present they lack sufficient knowledge.

The best thanks of the Board were accorded to Dr. S. G. Lukes on his retirement, for his services as examiner.

Scotland.

THE LISTER CENTENARY CELEBRATIONS IN GLASGOW.

WE have received a reprint from the *Glasgow Medical Journal* of the report of the proceedings in honour and memory of Lord Lister, which were recorded at the time in our issue of April 9th with considerable fullness. Perhaps the most interesting feature of that celebration which strikes us as we look over the pages of this reprint is the number of surviving pupils of Lister who took part in the commemoration. In particular the Clan Cameron mustered in great strength, Sir Hector Clare Cameron, Professor Emeritus Murdoch Cameron, and Dr. Irving H. Cameron of Toronto all made welcome contributions to the oratory of the meeting. The last named referred to Lister's two voyages across the Atlantic. On the first occasion (in 1876) he went to the international congress in Philadelphia; he was then in his fiftieth year and was still fighting for the general acceptance of the antiseptic system. His second visit was in 1897, when he went to Toronto to resign the office of President of the British Association, and to attend the annual meeting of the British Medical Association in Montreal, where he was

received with every honour as the man who had revolutionized surgery. The present occupant of Lister's professorial chair, Professor Archibald Young, proposed at the evening reception of the University a vote of thanks to the speakers, on which occasion, after touching on the religious ceremony of thanks in the cathedral church, which is so near a neighbour of the Infirmary, he laid stress on the great interest which the presence and speeches of those who had actually known and worked under Lister had for the succeeding generations of surgeons. This reprint with its illustrations, some of which were reproduced in our report, forms a pleasant souvenir of the great occasion which it commemorates.

A Border Practitioner's Reminiscences.

Local patriotism is a healthy sign in the national life, and we congratulate Selkirk on its *Book of Remembrance*,[1] in which is included so much evidence of pride in the town and in its history. In this pamphlet that veteran Dr. J. S. Muir gives, under the title "Sixty years agone," a highly interesting account of his experiences as a practitioner in the country around Selkirk. Many will sympathize with him in regretting that the horse has been superseded by the motor car, for there is a feeling of affection and sympathy between horse and rider which is necessarily absent in the relation of car and driver. Moreover, a horse may bring you safe home through a snowstorm or when you have lost your way, when the best of motor cars would be useless. We congratulate Dr. Muir on his abiding enthusiasm for the profession he adorns, and wish him many more years in the charming border town of which he writes.

Welfare of the Blind in Scotland.

The Scottish Board of Health has issued a circular of "advice to blind persons," describing the ways in which persons afflicted or threatened with blindness can now be assisted. The Board has also issued a pamphlet on the welfare of the blind for the information of "all ophthalmic surgeons, medical practitioners, hospitals, eye institutions, and nursing associations," as well as other persons or bodies likely to come into touch with blind persons. Children below 5 years of age may, if their homes are unsuitable, be cared for in a nursery school, maintenance being provided by the local authority under the Blind Persons Act, (1920). For blind persons between the ages of 5 and 18 education authorities are empowered to provide education, and, if it is given in a residential school, the local authority meets the cost of maintenance when the parents are not in a position to do so. Training is provided by education authorities at recognized centres in Edinburgh, Glasgow, Aberdeen, and Dundee. Employment after training may be found in institution workshops at Edinburgh, Glasgow, Aberdeen, Dundee, Inverness, and Paisley, while blind persons may also become enrolled in a home workers' scheme. Unemployable blind persons should be visited by a member of the staff of one of the outdoor societies, of which a list is given. Blind persons become eligible for old age pensions on reaching the age of 50 years, and a claim form may be obtained at any post-office. A residential home for aged or infirm blind women is provided by the Royal Blind Asylum and School, Edinburgh, and a home for men by the Royal Glasgow Asylum for the Blind.

Centenary of the Perth Royal Asylum.

The 100th annual report of James Murray's Royal Asylum, Perth, for the year ending March 31st, 1927, was submitted to the meeting held on June 13th. The asylum was founded by James Murray, who died in 1814. He had inherited a large fortune from a half-brother, and being unmarried, bequeathed the greater part of it "for the purpose of applying a certain part of the trust estate in the purchase of ground for, and the erection of, an asylum for the reception of lunatic persons in the said city of Perth and its neighbourhood." This design on the testator's part followed a Government inquiry instituted in 1813 to improve the terrible and notorious fate of the mentally afflicted throughout the country. James Murray, the founder, was a nephew of Andrew Marshall, whose researches at Bethlem Hospital resulted in the book on *The Morbid Anatomy of the Brain in Mania and Hydrophobia*, published in 1815, and it is probable that the founding of an asylum was directly instigated by the uncle. The asylum was opened in 1826, the architect being William Burn of Edinburgh, who also designed the first house of the Crichton Royal Institution at Dumfries. The first physician of the institution at Perth was William Malcolm, M.D., a practitioner in Perth, who acted as sole physician until 1836, when he was authorized to appoint a resident physician, Dr. Pierides. The Murray Asylum was originally built to accommodate 80 patients, but as early as 1838 additional wings were added for 60 extra patients. In 1848 the neighbouring property of Pitcullen Bank was purchased for the purpose of providing accommodation for private patients, but when the parochial patients were removed to Murthly Asylum in 1864 the Murray Asylum sold Pitcullen Bank, but only to repurchase it in 1907. The report, by Dr. W. D. Chambers, physician-superintendent, on the work of the asylum for the year 1926-27 shows that at the end of the year there were 163 patients in residence. The admissions numbered 68, an admission rate of 43 per cent. of the average population. Of the admissions 44, or 64 per cent., were on a voluntary basis. Attention is drawn to the importance of rest in bed in the open air, which is to a large extent provided by verandahs and shelters in the gardens of the institution. The use of ultra-violet radiation in the same connexion is also mentioned. Attention is drawn to the value of psychotherapy in its simpler forms of suggestion and persuasion, but it is noted that in spite of the large proportion of voluntary, and therefore presumably slight, cases among the admissions, it is rare to receive a resident patient in whose case anything so extensive as complete psychoanalytic would be helpful. With regard to discharges, 50 patients left the hospital during the year, of whom 22 were recovered, 23 relieved, and 5 not improved.

Edinburgh Scheme for Mental Defectives.

At a meeting of the Edinburgh Chamber of Commerce, on June 16th, it was stated that land at Gogarburn had been acquired for the purpose of a mental hospital, at a cost of £36,000. It was now proposed to make provision for 500 mentally defective persons immediately, and eventually for 1,000. An estimate had been obtained, and approved by the General Board of Control, for administrative buildings and stores, to cost approximately £40,000, and the next step would be to erect two wards to accommodate 100 patients. The Directors of the Chamber of Commerce expressed the view that the District Board of Control, before embarking upon expenditure of such magnitude, should bring the matter prominently to the notice of the ratepayers, who would have to bear the heavy burden which such a scheme involved.

Ireland.

Royal Medical Benevolent Fund Society.

From the report presented to the annual meeting of the Royal Medical Benevolent Fund Society of Ireland, held recently in the Royal College of Physicians, Dublin, it appears that the number of grants was eighty-one, as compared with eighty-five in the preceding year. The amount so disbursed in grants was £1,762, as compared with £1,747 in 1925-26. The average amount of grants has risen to £21 15s. 1d. The recipients of the grants comprised eight medical men, eleven orphans, and sixty-two widows. The audited balance sheet of the general fund showed an income from all sources of £1,974, as compared with £2,390 in 1925-26. Receipts from dividends and interest are down by £41, and the income tax refund was less by £13 14s. 3d. Under the head of donations and bequests there was a falling off of £221 10s. Subscriptions paid through the central treasurer, although there was a small increase in the number of individual subscribers, fell off by £21, due to smaller receipts from

[1] *The Book of Remembrance*, Selkirk, 1927. (7½ × 9¾, pp. 57; Illustrated.)

hospital collections, while those paid through branch treasurers were less than in the preceding year by nearly £20. On the other hand, receipts through the British Medical Association amounted to £106 10s. 6d., against £54 4s. 0d., an increase of £52 6s. 6d. This sum of £106 10s. 6d. is made up of subscriptions collected through the Association, £30 5s. 6d.; grant from the Association's Charities Fund, £50; and from the Medical Insurance Agency £26 5s. 0d. For these contributions the committee expressed its gratitude. Once again the Irish Medical Association gave £10, and the Dublin Clinical Club £5 5s. The committee entered the year with a carry-forward of £1,114, and it closed it with a balance to next account of £1,248. It is thus living within its income, but the falling off in the amount received from investments and in subscriptions affords cause for anxiety. At the beginning of the year the Osborne Fund was still in debt to the general fund to the amount of £4 8s. 2d. This debt has been wiped out, and the balance to the credit of the fund in the general balance sheet is £86 14s. 0d. No grants have been charged against this fund, but the committee will have to consider the question of renewing such charges during the current year. The committee, while thanking the subscribers for their support, asks each member to aid by canvassing for subscriptions and pressing the claims of the fund as opportunity may offer. The grants, small though they may be, mean a great deal to the recipients. With the money available the committee does what it can to aid the needy members of its own calling, and to help the widows and orphans of its professional brethren. There is no other fund in Ireland directly concerned with this work, and the apathy of the many medical men who contribute nothing to its support is deplored.

CONFERENCE OF THE INSTITUTE OF CLEANSING SUPERINTENDENTS.

The annual conference of the Institute of Cleansing Superintendents, held during the past week in the Mansion House, Dublin, was attended by many delegates from English and Scottish cities. Mr. James Jackson, O.B.E., salvage superintendent, Birmingham, was installed president for the third year in succession. President Cosgrave welcomed the conference to Dublin, and in the course of his address said that the people of Ireland had come closer to the realization of the fact that prevention of disease was in effect a national insurance, and that it led to a diminution in the sum total of physical suffering and to the prolongation of life. He also referred to the death rate in Dublin fifteen years ago, which, he said, was one of the highest at that time in Western Europe. Within the last four years the reduction was something like two per thousand. Dr. R. P. McDonnell, F.R.C.S.I., Deputy Chief Medical Adviser, Department of Local Government and Public Health, Ireland, read a paper in which he observed that the necessity for public cleansing did not exist in the rural communities, as farmers could always be relied on to find a suitable means of disposing of the domestic and stable refuse. In the urban areas communal action was needed to secure for the citizen conditions that would not react to the detriment of his health or comfort. The establishment of a well organized cleansing department was, therefore, the first duty of every urban authority. To the public health service the officials of the cleansing staffs were indispensable; without them they would be powerless to carry on the fight, and many of the triumphs of modern sanitation owed much to the help they had given. The prompt and efficient removal from the thoroughfares of the germ-laden contents of refuse bins was a factor in the modern crusade against epidemic disease. Dr. McDonnell went on to deal with dry closets and ashpits, and said that unfortunately they were still to be found in the small towns and villages. The people had but the most elementary ideas of the laws of hygiene, and it was regrettable that hygiene did not find a place in the curriculum of the schools. Ashpits, he was glad to say, had virtually disappeared from Dublin; but they were still to be found in almost every town and village in the country. The whole method of dust and refuse removal called for improvement. The extermination of the fly should be the aim of the cleansing superintendent.

Correspondence.

TRAUMA AS A CAUSE OF AURICULAR FIBRILLATION.

SIR,—With reference to Dr. Harris's letter of May 28th, it is clear that since April 30th he has made a definite advance in his conception of auricular fibrillation. He no longer maintains that "there has not been one shred of dependable evidence produced which would suggest that trauma may induce fibrillation in a healthy heart"; for he now quotes Sir Thomas Lewis's statement—that fibrillation, started in a healthy heart by means of electric stimuli, may persist even for thirty to sixty minutes after the stimulus has ceased. It almost looks as if we shall soon be in entire agreement.

Perhaps I was wrong in suggesting that Dr. Harris held that "fibrillation in itself was evidence of myocardial damage." He vigorously denies the soft impeachment, but surely he gave me every reason for concluding that such was his view, since on April 30th he wrote: "wherever we find auricular fibrillation there we also find a damaged heart," and also, "in order to induce fibrillation it is essential that the heart must be damaged beforehand." I fail to see in what way I have misrepresented him.

Dr. Harris affirms that the important question from the medico-legal or practical point of view is whether trauma can or cannot induce fibrillation in a *healthy* heart. This is not correct. What is really of moment from the medico-legal aspect is whether trauma may not prove the exciting or determining factor in the production of fibrillation in any heart—pathological or otherwise. Whether trauma can induce fibrillation in a *healthy* heart is of scientific interest only. It is satisfactory to note that Dr. Harris acknowledges the possibility of fibrillation in such a heart, and—of still more significance—admits that fibrillation, once begun in a healthy heart, may persist after the cessation of the exciting stimulus.

His only difficulty now is in accepting our opinion as to the integrity of the hearts of the four patients whom we class as "apparently normal so far as can be determined by ordinary clinical methods." This phrase appears to be distasteful to him—he calls it "meaningless." But a man is in truth more bold than wise who will guarantee the integrity of any individual, from skin to core.

After carefully reading Dr. Harris's letters one is led to infer that he has arrived at his conclusions by the process of disregarding both the subjective evidence of the patients and the clinical findings advanced by us in our initial communication and subsequent correspondence.

I think he will agree that the following fairly represents his conclusions, up to date, in regard to our cases: First, their hearts were diseased; secondly, in any event, we are not justified in assuming any causal relationship between the trauma and the fibrillation; and thirdly, the fibrillation was probably present before the trauma.

In fact, the above only lacks one further contention—"the finishing touch"—that the patients never fibrillated at all.—I am, etc.,

JOHN HAY.

Liverpool, May 31st.

AURICULAR FIBRILLATION.

SIR,—With reference to Dr. Milner Moore's "personal experience" (BRITISH MEDICAL JOURNAL, June 11th, p. 1083) is it not in keeping with familiar experience that, clinically, there are two types of delirium cordis, *alias* auricular fibrillation—the one benign, the other malign? The former unimportant, as being relatively innocent; the latter important, because it tends to develop circulatory failure, its malignity in exact proportion to the degree of this tendency. As to the former, let me quote Sir James Mackenzie (*Diseases of the Heart*, fourth edition, p. 202): "I have already said that there are a great many individuals with fibrillation who lead useful energetic lives and whose capacity for work is little, if at all, impaired by the new rhythm."

It is interesting here to learn that in 1912 Dr. Moore consulted Sir James, who "at first did not recognize the

disease" (though it should have given a typical sphygmogram with the polygraph, if the finger could detect a delirium cordis), but finally decided that the complaint before him was auricular fibrillation—and this on the strength of the electro-cardiograms obtained. The pronouncement leaves us in the dark as to the type of the disorder, harmful or innocent, but I incline rather to infer that the diagnosis arrived at was of the more definite (serious) malady. This was in 1912, and the special interest attaching to the date is that by 1924 we know that Sir James had changed his opinion concerning the serviceableness of the electro-cardiograph, which by then he had found to be of "little or no help" in his investigations into "the functional capacity of the heart or heart failure" (BRITISH MEDICAL JOURNAL, January 19th, 1924, p. 105). This adverse opinion he does not hesitate to accentuate in the fourth edition of his book (1925, p. 428): "Already the history of the electro-cardiogram, brief as it is, shows how vain and futile have been many of the interpretations of the records taken from the human heart." Yet surely the physician's essential quest is the presence or absence of heart failure, whether in actual being or in the approach; for what have we, as practical therapeutists, to do with mere abnormality, manifesting itself only as a freakish behaviour, which does not impair functional capacity? In the opinion of Sir James Mackenzie, then, the electro-cardiograph will be useless for the purpose of differentiating between the two types of auricular fibrillation.

It remains to ask whether, failing the electro-cardiograph, the polygraph will serve our purpose. As to this, I would say that I have published my reasons in full for believing that the present interpretations of the polygraphic tracings are incorrect and, if so, the conclusions also which have been drawn therefrom. For the present, then, we must fall back upon the older methods of clinical investigation and seek from symptoms and signs to gauge the capacity of the heart to meet the demands which are being presented by the circulation of the blood in each particular case. This may seem rather dull, but should it be? Are the potentialities of symptoms and signs exhausted? Is the Hippocratic method to be shelved finally? Nay, rather, is it not certain that, in the investigation of any and every new line of research, the final court of appeal will always be the Hippocratic *argumentum ad Aegrum*, whence we shall look for the verdict "*bonum*" or "*malum*" as the case may be?—I am, etc.,

London, W.1, June 11th. HARRINGTON SAINSBURY.

DRUGS FOR SLEEPLESSNESS.

SIR,—No one with first-hand knowledge of the prevalent practice in the treatment of sleeplessness can, I imagine, be surprised that Sir Maurice Craig has promptly subjected Sir William Willcox's views to criticism in the light of his own experience. But there is more involved than comparison of results obtained under two different methods of inquiry. There are the further questions, first, how to estimate the clinical significance of defective sleep, especially in the early stages of mental breakdown (whether sleeplessness is regarded as cause or symptom is a matter of indifference in the present discussion); and, secondly, what place should be given to the prompt use of hypnotics?

If sleeplessness is looked on as a matter of primary importance it is likely that its treatment will be regarded in a much more serious light than appears to be customary. Sir Maurice Craig claims freedom, and the curious thing is that this claim has always had to be made in the case of hypnotics. Every hypnotic has been "scientifically" condemned, and the condemnation has always been accompanied by a certain suggestion that the prescriber as well as the patient is, or is likely to become, an odious person. Whisky—the night-cap—is probably the most widely used hypnotic in this country, and yet every doctor's library contains volumes on the evil effects of alcohol on the human system and the social order. The fact remains, however, that popular opinion, including the non-vocal but convincing testimony of personal habit, even among medical men, remains unaffected by scientific opinion, by teetotal clamour, and by high taxation, and most people accept the lines of Robert Burns as the proper conclusion of the whole matter:

> "Freedom and whisky gang together,
> Take aff your dram."

But why this freedom? The answer is quite unambiguous. It is in order to ask "the medical profession to treat defective sleep far more seriously than has been the custom in the past." Sir Maurice Craig, it seems to me, is justified in his effort to clarify the true issue, and in doing so he has some right to claim to put his personal experience before the profession, not merely—nor even chiefly—as testimony to the value of the drugs more immediately under notice, but to point to the serious nature of the maladies in the treatment of which he has found them useful, and to warn the profession of the danger of neglect, through unfounded fears, of measures for their prompt and efficient treatment. The practical object he has in view is to assist in reaching an adequate appreciation of the values that properly belong to the practical, as well as the theoretical aspects of the subject.

When one considers the number of disastrous incidents which constantly come to light, mostly traceable to failure to attach adequate clinical significance to defective sleep, or to use efficient remedies for it, one welcomes an attempt to awaken interest in the subject.

The sole object of this letter is to endeavour to fix attention on what I conceive to be Sir Maurice Craig's intention, and although my personal experience has run on somewhat different lines, I cordially place myself by his side in the general point of view he has presented.—I am, etc.,

London, W.1, June 19th. JOHN CARSWELL.

SIR,—I must apologize for further trespassing on your valuable space, but feel that a reply is needed to the letter of Sir Maurice Craig in your last issue.

It contains the astonishing statement that he is fully in agreement as regards the toxicity of sulphonal and trional, but apparently the toxicity of the barbitone group of drugs is disputed.

There is overwhelming evidence that on human beings the barbitone group of drugs are, weight for weight, much more toxic than the sulphonal groups. The Registrar-General's returns for England and Wales show for the twenty years 1906-25 inclusive a total number of 253 deaths from the barbitone group of drugs, while the total number of deaths from poisons of the sulphonal group is only 53 for the same period.

The British Pharmacopoeia Committee of the General Medical Council, after careful deliberation, gave in the last edition of their work a maximum dosage of 10 grains for barbitone and 30 grains for sulphonal, figures which to my mind give an approximate idea of the relatively higher toxicity of veronal as compared with sulphonal. All authorities are agreed as to the still greater toxicity of other higher barbitone compounds, such as luminal, dial, allonal.

I have on several occasions seen dangerous coma result from 50 grains of veronal, which may be regarded as an average fatal dose. In 1913 I read at the International Congress of Medicine in London what I believe was the first paper published in this country on "Veronal poisoning," and since that time have given the subject my closest attention, and have had a very extensive clinical as well as toxicological experience of the use of the barbitone group of drugs.

I have not the slightest doubt that the barbitone group of drugs possess potent toxic properties on man, and I beg of the medical profession to exercise great care and caution in the prescription of these drugs.

Sir Maurice Craig asks: "Where are the addicts, and what are they doing?" My answer is that many of them are dead and buried, as the result of fatal veronal poisoning and suicide from other causes. It is something more than a coincidence that in a large proportion of the veronal fatalities there has been to my personal knowledge definite evidence of previous addiction to the drug.

I have met with a number of persons suffering from veronal addiction in my own practice, and many of my

medical friends with whom I have discussed the subject have had a similar experience. The subjects of addiction to this group of drugs are often brain-workers and people of high intellectual grade. In addition, I have very strong grounds for believing that veronal addiction, like other forms of drug addiction, is relatively common amongst the pleasure-seeking class of the night-club type.

I have on several occasions seen dangerous nervous symptoms, such as ataxy, anarthria, diplopia, etc., result from the daily use of the drug in therapeutic doses. Some of these cases were quoted in my paper, and others have observed many similar cases.

I am fully aware that persons suffering from active mental disease can often tolerate large doses of hypnotic drugs over relatively long periods, and that it may be necessary and advisable in such cases to use the barbitone group of drugs daily over long periods, provided that the patient is under close medical observation. This may explain the wide discrepancy between the experience of Sir Maurice Craig and myself.

I stated in my recent paper (which unfortunately Sir Maurice Craig has not read) that

> the barbituric acid compounds "are rapidly acting and fairly certain hypnotics. It is for this reason that they are so commonly used. A single therapeutic dose is usually followed by a satisfactory period of natural sleep, and no marked after-effects follow when the therapeutic action has passed away, which should be after six to twelve hours."

The view that these drugs may be given in therapeutic doses daily over long periods to persons who are not suffering from active mental disease is, in my judgement and experience, most dangerous and misleading teaching.—I am, etc.,

London, W.1, June 20th. W. H. WILLCOX.

MINERS' NYSTAGMUS.

SIR,—Appearance of the articles dealing with miners' nystagmus in your issue of June 18th prompts me to send you the following paragraph taken from some notes (already in print) based on observations made by me during a short visit in the early part of this year to the United States:

"*Miners' Nystagmus.*—Opportunity was seized while at Pittsburg of gaining acquaintance with the coal-mining industry. Here, also, *more medical services are provided than in this country; but the* most striking difference in underground practice is the illumination provided. There was no need for waiting on leaving the cage to 'get your eyes'; the walls of the workings were white, and reflected the light from the lamps, stone dusting being always done with limestone or gypsum. The electric safety lamps used gave more light than ours, and were different in shape, being worn in the cap with the battery attached to the waist. This is the position which of old the miner chose for his naked candle, and still chooses in naked-light pits. No further reason need be sought for the entire absence of nystagmus among American coal-miners. One miner said that he and his son while mining in Yorkshire had suffered with eye movements, but that both had lost their troubles within two months of taking up mining work in America."

—I am, etc.,

EDGAR L. COLLIS,
Cardiff, June 18th. Member of Miners' Nystagmus Committee.

SIR,—I wish cordially to support the plea of Dr. Freeland Fergus in the JOURNAL of June 18th (p. 1092) for a thorough investigation of miners' nystagmus. There seems no other disease in which is to be found such a tangle of contradictory observations and beliefs. Even the official definition contradicts the term it should define: "The disease known as miners' nystagmus, whether occurring in miners or others and whether the symptom of oscillation of the eyeballs be present or not." The consensus of ophthalmological opinion is that bad illumination is the cause of the trouble, but Dr. Fergus shows that improved illumination is often followed by the onset of symptoms.

Dr. Robson in his article says ". . . the pathological entity round which this complex revolves is involuntary oscillation of eyeballs." Dr. Fergus writes on the previous page: "cardiac instability is much more frequently present than rotation of the eyeballs." Dr. Robson adds to the confusion when he notes that "subjective symptoms without objective signs may be the chief determining characteristic."

The absence of *post-mortem* examinations is a startling revelation: yet material has been provided by suicides ascribed to this mysterious disease. It appears from these articles that research hitherto carried on has been worse than useless, and that the only course is to scrap all our present beliefs, disregard all previous observations, and start afresh.—I am, etc.,

Southsea, June 21st. W. S. INMAN.

PALATE OPERATIONS.

SIR,—Sir Robert Woods, in your issue of February 26th, writes an interesting note on aids to palatal sufficiency after cleft palate operations, but he twice makes the statement that a cleft palate operation may be quite "good" and "successful" and yet leave a "hiatus behind the palate" either "literally huge" or "so great as to look quite hopeless." It is difficult to reconcile the two portions of the statements—for how can any operation be deemed to be successful if its primary object is not attained? As I have pointed out (*Der Wolfsrachen und Seine Behandlung*, 1913, *Stomatology*, 1912 and 1924, *Facial Surgery*, 1924), the primary object of any cleft palate treatment is to enable the posterior margin of the soft palate to approximate to the posterior pharyngeal wall; it is infinitely more important to attain this than to close the cleft in the palate.

Some of my patients who have fully functional soft palates after operation, but in whom, for one reason or another, I have not touched the cleft in the hard palate, speak, even without a plate, with most extraordinary distinctness. Anyone can "close" any cleft by utilizing all the available tissue in a lateral direction at the expense of the antero-posterior direction—at least the "hole in the palate" looks closed to the parents and friends; but it is not closed, it is merely *transferred* from the palate to the oropharynx. This mere transference of the cleft from one position to another is brought about too often, I think, by the rigid adherence to the Langenbeck operation. The antero-posterior measurement from the hard palate to the pharynx differs considerably in different patients. When it is not long and there is sufficient tissue, the Langenbeck is a perfectly good operation; where, however, it is longer *than usual*, and/or the tissue available is less than normal, then the Langenbeck operation gives bad results, a short or a rigid soft palate inevitably resulting, with consequent loss of function. In the latter type of case either a "*velum*" operation only should be done—with subsequent provision of a hinged artificial palate—or a skin-grafted flap operation. In very wide clefts, in order to avoid using up too much tissue in a lateral direction, a preliminary partial Brophy operation is also often a necessity, the indication being that the lower jaw fits up inside the upper jaw. Used with discrimination, I have never seen other than the most beneficial effects follow this operation. In any case there should be *no tension; tension and function* in any plastic operation are incompatible. I agree that the treatment of these short and functionless palates (after unsuccessful operation) is very difficult.

The paraffin wax injection suggested by Sir Robert Woods might help considerably, I should imagine, if it does not interfere with the function of the superior constrictor of the pharynx. I have usually contented myself with lengthening the palate by flaps from the pillars of the fauces or by having a solid obturator made, attached to an extension from a dental plate, on to which the superior constrictor may close, and I must say that I think the latter plan gives the better functional speech result. In planning any cleft palate operation I usually tell students that they should choose that form which will best please the child in ten years' time, not that which will best please the parents at the moment.—I am, etc.,

University of Otago, April 27th. H. P. PICKERILL.

THE SCHICK TEST.

SIR,—A ward maid at the Croydon Hospital, at the time Schick-negative and quite well, was found on taking a swab to have in her throat virulent diphtheria germs, which killed a guinea-pig in thirty-six hours.

It would appear that we must look for the dangerous carrier amongst the Schick-negative persons. The Schick-positive are not so dangerous, as if infected their sore throats at once betray them.—I am, etc.,

G. GILBERT GENGE, M.D.,
Physician, Croydon General Hospital.

June 7th.

INTRATRACHEAL INJECTION OF IODIZED OILS.

SIR,—The estimation of the dangers of introducing iodized oil into the trachea and bronchi by Drs. Archibald of Montreal and A. L. Brown of San Francisco (BRITISH MEDICAL JOURNAL, June 4th, p. 1023) may serve as a warning against the adoption of this means of examination without the consideration of the dangers which may arise.

The selection of suitable cases will rest with the physician and will exclude cases of pulmonary tuberculosis in which there is haemorrhage or pyrexia, and all suppurative cases in which there is fever. When absolutely necessary, however, such cases might be examined by the introduction of lipiodol diluted to half strength by means of almond or pea-nut oil; the risk of the injection causing untoward symptoms would be considerably lessened and the intensity of the radiographic shadow not seriously decreased.

For some time I have adopted the radiological methods elaborated by Dr. J. V. Sparks and communicated by him to the Röntgen Society in April, 1927. The injection of the iodized oils is controlled by means of fluoroscopy before the radiograms are taken. The screening must include the site of the introduction of oil, more especially if the intercricothyroid route be selected. The injection completed and the exposures made, some minutes are allowed to elapse, during which time the patient should, if possible, sit up. A screen examination of the oesophagus and the stomach should then be made, and the detection of any trace of the iodized oil in these organs should be an indication for immediate lavage.

The introduction of iodized oil into the trachea and bronchi is an excellent diagnostic procedure in selected cases, and I think that the slight risks which undoubtedly exist can be considerably minimized by the closest co-operation between the physician and the radiologist, and more particularly by the technique of the latter; in no examination is more skill required, and the actual taking of the films is a part, and the less important part, of the problem before him.—I am, etc.,

E. J. H. ROTH, M.R.C.S., L.R.C.P.,
D.M.R.E.Camb., Chief Assistant in the X-ray Department, St. Bartholomew's Hospital.

London W.1, June 6th.

INFLUENZA AND ALBUMINURIA OF PREGNANCY.

SIR,—The universal opinion that acute nephritis is caused by a toxin may possibly fall as a result of Dr. Ambrose Owen's admission that compression of the kidney is or may be a determinant of albuminuria. That such a causal nexus exists in influenza—in spite of the cough, which when persistent wracks the patient, and, as the manometer shows even in the normal, causes such a rise of intra-abdominal pressure and must do so more than ever in pregnancy—he will not allow. In influenza a toxin is at work: compression of the kidneys is not "*the* cause of albuminuria in the cases under consideration." The deduction, vitally important, is that in other cases it may be.

It seems at the moment impossible to explain acute nephritis. One of the first questions to answer is: What is the relationship, if any, between "albuminuria" and "acute nephritis"? The attribution of the latter to a toxin—it matters not which sort—is easy and satisfies most. How curious to note that in scarlet fever acute nephritis usually occurs many days after the specific toxaemia has disappeared; and that in many cases of nephritis no antecedent infection can be traced. We are not yet conversant with all the forces of the body which conjointly maintain health, or which, departing for the moment in some respect or other from the normal, either as a result of environmental change or of change arising within, determine a pathological phenomenon of magnitude. We have a long way to go yet before we understand the cause even of elementary and insignificant deviations from normal.—I am, etc.,

Rugby, May 26th. R. H. PARAMORE, F.R.C.S.Eng.

TREATMENT OF HALLUX RIGIDUS.

SIR,—Mr. Cochrane's view that the functional end-result of treatment of hallux rigidus is in a large number of cases unsatisfactory (June 18th, p. 1095) is widely accepted by those who take the trouble to observe their end-results. His endeavour to supplement the measures available by the introduction of a capsulotomy is praiseworthy, but the value of an otherwise excellent article is reduced by the indefinite account of the indications and limitations of the operation. We cannot regard his procedure as "an effective substitute" for other operations.

It has long been my belief that one of the causes of failure in the treatment of hallux rigidus is the very generally accepted view that it is, in itself, a clinical entity. It is not. It is merely an expression of metatarsophalangeal arthritis, which, like arthritis elsewhere, may be due to any one of a score of causes. To attempt to treat such a group of diseases by a single routine bone operation is as intelligent as to attempt to treat every arthritis of the knee by excision of the joint.

It is my custom to classify arthritis here, as elsewhere, into traumatic, "degenerative," and infective types. The traumatic arthritis is almost invariably due to the stubbing of the great toe by a short boot. Spasm of the short flexor muscles results, contracture of the ligaments and capsule follows, and finally bone changes may occur. In the earliest stage of muscle spasm a bone operation is an improper procedure, and no more is necessary than to protect the joint from further injury. But it must be insisted that the common practice of applying a metatarsal bar to the very boot which is causing the condition does not constitute protection. The first essential is not a bar, but a boot of correct length, and the correct size of boot can only be determined by measuring the feet with a bootmaker's measure-stick, which is as essential to an orthopaedic surgeon as a stethoscope to a physician. In my hospital orthopaedic clinics measurement of feet and boots is a routine procedure, and very interesting and instructive facts are to be elicited. One frequently finds patients—especially children and women—wearing boots one or two sizes too small. When the correct size of boot is worn (three sizes larger than the number indicated on the measure-stick) all symptoms disappear. It is very common to find patients with feet of unequal length, with a unilateral hallux rigidus affecting the longer foot. Measurements show that, although the boots are the correct size for the shorter foot, they are too small for the longer foot.

The second stage of the traumatic type of hallux rigidus, where capsular contracture is commencing, may respond to manipulation under anaesthesia, followed by protection as above. But, as would be expected by analogy with other joints, there is a later stage of capsular contraction where manipulation is ineffectual and an open operation is demanded. It is here that Mr. Cochrane's procedure will find its scope. I have on several occasions practised a similar operation in this type of case, but before actually dividing the capsule I have performed a muscle slide of the short flexor muscles, similar in principle to the operations of Steindler for claw-foot, Souttar for paralytic flexion of the hip, and Max Page for Volkmann's contracture. After operation the toe is put up, usually in plaster, in the corrected position, and movements are instituted in a few days. The result of a muscle slide should be more permanent than that of a simple tenotomy. The results have been satisfactory when the cases have been judiciously selected. My present routine is to attempt manipulation and protection first, and to go on to muscle slide and capsulotomy later, if palliative treatment should fail.

In the final stage, where the pathological changes have gone on from capsular contraction to cartilaginous erosion

and osteophyte formation, a bone operation is clearly indicated, whether it take the form of Mayo's operation, Kellar's operation, or a modified procedure. I have usually found that complete correction can be obtained without capsulotomy, if a bone operation is performed.

Other types of traumatic arthritis include the arthritis following fractures of the metatarsal head, base of the phalanx, and sesamoids: there is the type associated with flat-foot which, as a result of irritation of the tarsal joints, has been complicated by muscle spasm, most evident in the peronei, but also present in other muscles of the foot and toes. There is, moreover, the degenerative form of true osteo-arthritis of the joint, and many types of infective arthritis may occur in which the prominent physical sign is rigidity of the great toe. One has seen gouty, tuberculous, and gonococcal "hallux rigidus." The term "tonsil foot" has been applied to the hallux rigidus of young adults which is secondary to distant foci of infection, and every surgeon knows the resistant rigidity of the great toe which may arise in rheumatoid arthritis. There can be no routine treatment for all these affections—appropriate forms of therapy are to be adopted as elsewhere in the body.

In conclusion I would reiterate that rigidity of the great toe is merely a physical sign of arthritis, and that there are many forms of arthritis, each demanding its specific treatment. Arthritis of this joint should not be regarded as a peculiar and isolated condition, but treatment should be governed by the principles which apply elsewhere. In so far as Mr. Cochrane's article stimulates this view, by the application of a well known operation to the particular joint in question, I welcome it.—I am, etc.,

R. WATSON JONES, B.Sc., M.Ch.Orth.,
F.R.C.S.Eng.,
Honorary Assistant Surgeon, Orthopaedic Department,
Liverpool Royal Infirmary.

June 19th.

MEDICAL MEN IN PARLIAMENT.

SIR,—Dr. Vernon Davies's argument that membership of Parliament should be a full-time job would, if pushed to its logical conclusion, restrict entry to Parliament to professional politicians. If politics is to be a profession, training for it should, as in any other profession, begin early, and the amateur politician, coming into politics from other occupations, who constitutes nine-tenths of the present House, would vanish. The professional politician has never been looked upon with too much favour in this country, and a House consisting entirely of professional politicians seems to me a nightmare. But Dr. Davies really supports the main argument of my address when he states, quite accurately, that members who have interests and occupations outside Parliament form the large majority of the House. All that I contended was that in the clash of sectional interests which make up the House as at present constituted, medicine is very inadequately represented. Of course, medical men entering Parliament must be prepared to make large sacrifices both of time and money, as I sufficiently stressed in my address, but that a very abundant measure of professional practice can be combined with parliamentary work has been demonstrated very fully by the numerous eminent lawyers who adorn the House. Dr. Davies's argument that a man retired from practice can reflect medical opinion equally well with those in active work will not, I think, convince anyone; he is obviously himself only half-hearted in advancing it. May I in a small personal explanation say that my conception of my duties has *not* been to restrict my participation in parliamentary work to the "safeguarding of the interests of my University," although these are naturally of paramount importance to me, but I have considered myself as in some degree representing medicine as well, and have, where possible, taken a share in defending its interests. The House is rightly intolerant of men butting in on subjects of which they know little, and I have confined myself in debate to educational and medical subjects on the whole.

In answer to Dr. Nathan Raw's courteous note, I may point out that your summary of my address—excellent as that summary was—was necessarily somewhat truncated, and that I had no intention of conveying the impression that our present committee was the first of its kind. But in the new Parliament of 1924 the medical members were probably more split up into parties than was the case in 1918, and in 1924 serious doubts were expressed as to whether it would be possible to sink party differences upon professional matters, and whether it would be in fact desirable to reconstruct the committee under the then conditions. Experience has shown that this was entirely feasible, and the committee has been extremely active throughout the present Parliament.—I am, etc.,

House of Commons, June 20th. E. GRAHAM LITTLE.

THE FAMILY DOCTOR.

SIR,—Eloquent idealism and practical suggestiveness will attract attention to the lecture by Dr. C. E. Douglas, published in your issue of June 18th (p. 1120). That the mainspring of general practice is ethics, not cash, is, at least as sound philosophy as that of Romeo's apothecary, and few will maintain that the authors of the National Health Insurance system had the greatness of mind to appreciate this sober fact. Dr. Douglas breathes a prayer that it may some day be possible to hark back to the fundamental truth, that the doctor's work is the treatment of disease and nothing else. May I venture to place this pious wish in conjunction with a quotation from the report of the Royal Commissioners. "The ultimate solution," they think, "will lie in the direction of divorcing the medical service entirely from the insurance system."[1] Were this divorce accompanied by (1) restriction of the State medical service to the genuinely necessitous poor, and (2) a system of insurance against the financial risks of sickness, it would remove from general practice the greatest of the deteriorating influences which Dr. Douglas sees in his vision of the present, and help enormously to clear the way from the glories of the past to the achievements of the future.—I am, etc.,

Wandsworth, S.W., June 20th. ROBERT CARSWELL.

SIR,—I would, as a panel doctor who has worked under the insurance since its inception, like to register a protest against Dr. Douglas's statements about insurance practitioners. If he is a panel doctor he, of course, knows best the type of work he does. If he is not a panel doctor I cannot congratulate him on his good taste. Every inquiry that has been made into the working of the Act has been eloquent on the excellence of the doctors' work.

When I think of the old club system from which we have escaped I feel emancipated, not degraded. My experience differs from Dr. Douglas's. I have never met any doctor who was not in medicine for what he could honestly get out of it. It may be that the Mecca of altruism lies in the East, and even in Fifeshire, but I "hae ma doots."

I cannot see that any noble and altruistic mind would hold such a poor opinion of the great majority of the rest of his fellow doctors.—I am, etc.,

Dennistoun, June 18th. JAMES COOK.

The Services.

INDIAN MEDICAL SERVICE.

ANNUAL DINNER IN LONDON.

THE annual dinner in London of the Indian Medical Service was held on June 15th, when Major-General R. W. S. Lyons was in the chair, and ninety officers and two guests were present. At the dinner this year the chairman had on the table in front of him a gold cup of elegant pyramidal form, which had been presented by the members. It bore on its base the names of the founder and of the honorary secretaries, and of all the officers who have presided at the annual dinners since the Indian Medical Service Fund was founded in 1897, through the exertions of the late Colonel Sir Peter Freyer. At the first and second dinners the late Sir Joseph Fayrer, Bt., F.R.S., was in the chair, and his name is followed by a long and distinguished list. The dinner is an agreeable social function, when old friends meet, and for long there were no speeches

[1] Report of the Royal Commission on National Health Insurance, para. 138, p. 65.

Recently the practice of a few speeches has crept in, but it is intended that they shall all be short. On the present occasion the toast of "The Indian Medical Service" was proposed by the chairman in a reminiscent speech, and acknowledged by Major-General T. H. Symons, C.S.I., Director of the Service, by Major-General W. H. Ogilvie, C.B., Director of Medical Services, India, and by Air Vice-Marshal D. Munro, C.B., C.I.E., who began in the I.M.S., but was not long ago transferred to the Royal Air Force Medical Service, of which he is Director-General. After speaking of the affection in which he still regarded his old Service, he concluded by proposing the toast of "The Honorary Secretaries," Colonel J. J. Pratt and Colonel John Anderson, C.I.E., who both replied briefly. The valuable services rendered by the honorary secretary in India, Lieut.-Colonel J. K. S. Fleming, were specially acknowledged. The following is a list of the officers present:

Major-Generals: Sir R. H. Charles, G.C.V.O., K.C.S.I., B. H. Deare, C.I.E., G. F. A. Harris, C.S.I., Sir P. Hehir, K.C.I.E., C.B., C.M.G., H. Hendley, C.S.I., W. H. Ogilvie, C.B., C.M.G., J. B. Smith, C.B., C.I.E., T. H. Symons, C.S.I., O.B.E. *Air Vice-Marshal:* D. Munro, C.B., C.I.E. *Colonels:* H. Ainsworth, Sir H. E. Banatvala, C.S.I., J. K. Close, J. Crimmin, V.C., C.B., C.I.E., C. M. Goodbody, C.I.E., D.S.O., J. A. Hamilton, C.M.G., A. W. M. Harvey, A. J. Macnab, C.B., C.M.G., R. A. Needham, C.I.E., D.S.O., J. J. Pratt, H. Austen Smith, C.I.E., R. G. Turner, C.M.G., D.S.O., F. Wall, C.M.G., C. N. Wimberley, C.M.G. *Lieutenant-Colonels:* J. Anderson, C.I.E., W. M. Anderson, C.I.E., F. A. Barker, O.B.E., G. T. Birdwood, J. T. Calvert, C.I.E., R. Markham Carter, C.B., A. W. Cook-Young, D. G. Crawford, J. M. Crawford, O.B.E., H. R. Dutton, R. H. Elliot, J. Entrican, C.I.E., G. H. Frost, J. Fuller-Good, H. Greany, E. V. Hugo, C.M.G., J. B. Dalzell Hunter, O.B.E., J. G. Jordan, H. C. Keates, H. Kirkpatrick, J. C. G. Kunhardt, Clayton Lane, W. B. Lane, C.I.E., C.B.E., W. T. McCowen, G. E. Malcolmson, W. A. Mearns, F. O. N. Mell, C.I.E., A. Miller, T. R. Mulroney, F. O'Kinealy, C.I.E., C.V.O., A. S. M. Peebles, V. Heathcote Roberts, Sir L. Rogers, C.I.E., F.R.S., E. R. Rost, O.B.E., F. B. Shettle, O.B.E., S. Browning Smith, C.M.G., R. Steen, T. G. N. Stokes, Ashton Street, W. A. Sykes, D.S.O., H. H. Thorburn, C.I.E., W. H. Thornhill, D. P. Warliker, H. G. L. Wortabet, A. C. Younan. *Majors:* C. H. P. Allen, F. J. Anderson, *M.C.*, L. A. P. Anderson, C. L. Bilderbeck, Sir T. J. Carey-Evans, *M.C.*, N. H. Hume, W. D. Keyworth, F. J. Kolapore, S. H. Middleton-West, *M.C.*, C. Newton-Davis, *M.C.*, M. J. Quirke, J. Scott, D.S.O., O.B.E., R. S. Townsend, *M.C.* *Captains:* E. Cotter, P. A. C. Davenport, G. R. McRobert, R. C. Malhotra, O.B.E., C. M. Nicol, S. R. Prall, T. H. Thomas, H. Williamson.

The guests were Sir Dawson Williams, C.B.E., *British Medical Journal*, and Dr. E. C. Morland, the *Lancet*.

AGE OF RETIREMENT.

A ROYAL WARRANT, dated June 10th, has been issued by the India Office amending the Warrant of June 13th, 1919, in respect of the age of retirement of I.M.S. officers holding administrative appointments. The essential clause of the new Warrant is as follows:

"Our Will and Pleasure is that General Officers shall be placed on the Retired List at the age of 60 instead of as heretofore at the age of 57. It is Our Further Will and Pleasure that the provision whereby a General Officer holding an administrative appointment may be continued in employment for not more than one year in any special case where it appears to Our Governor General in Council to be for the good of Our Service, shall be cancelled."

DEATHS IN THE SERVICES.

Colonel Edward North, C.B., Army Medical Service (ret.), died at Worthing on June 6th, aged 70. He was born at Ropley, Southampton, and was educated at St. George's; he took the L.R.C.S.Ed. in 1879, and the F.R.C.S.Ed. in 1883. He entered the army as surgeon in 1880, attained the rank of Colonel in 1906, and retired in 1910. He served in the South African war of 1900-1902, when he took part in the operations in Cape Colony, including the action of Colesberg on January 1st, 1900; in the Orange Free State, later the Orange River Colony, including the actions at Paardeberg, Poplar Grove, Dreifontein, Houtnek (Inoba Mountain), Vet River, Zand River, Bethlehem, and Wittebergen; and in the Transvaal, in the actions at Johannesburg, Pretoria, Diamond's Hill, and Elands River; was mentioned in dispatches in the *London Gazette* of April 16th, 1901, and received the Queen's medal with five clasps. After his retirement he rejoined for service in the great war (1915-17), was again mentioned in dispatches, and received the C.B. in 1917. He was unmarried.

Colonel Henry Octavius Trevor, Army Medical Service (ret.), died at Torquay on June 3rd, aged 67. He was born at Nether Stowey, Bridgwater, and was educated at St. Thomas's; he took the L.S.A. in 1880, and the M.R.C.S. in 1881. Entering the army as surgeon in 1882 he became colonel in 1911, and retired in 1917. He served in the Burmese campaign in 1885-87 (medal with clasp); in South Africa from 1899 to 1902 (Queen's medal with clasp, King's medal with two clasps); and as A.D.M.S. in the recent great war. He was a younger brother of the late Surgeon-General Sir Francis Wollaston Trevor, K.C.S.I., Army Medical Service, who died on November 16th, 1922.

Major Charles Hildred Brodribb, I.M.S. (ret.), died, after long years of illness, at Penmaenmawr, North Wales, on May 27th. He was born on October 30th, 1876, educated at St. Mary's Hospital, and graduated M.B. and B.S.Lond. in 1900; he took the M.R.C.S. and L.R.C.P.Lond. in the same year. After serving as house-physician, house-surgeon, and clinical assistant in the throat department at St. Mary's, as senior house-surgeon of Scarborough Hospital, and as house-surgeon and anaesthetic and clinical assistant at Tottenham Hospital, he entered the I.M.S. in 1903. He became major on February 28th, 1915; he was placed on the temporary *non*-effective (half-pay) list on account of ill health in 1922, and retired in the same year. During the war he served as surgical specialist to the 5th and 9th Divisions of the Indian Army.

Captain John Furse McMillan, R.A.M.C. (ret.), died suddenly at Sandown, Isle of Wight, on May 31st, aged 67. He was born at Southmolton, Devon, on August 24th, 1859, educated at the Middlesex Hospital, and took the M.R.C.S. and L.R.C.P.Lond. in 1882. After serving as house-physician at Middlesex Hospital, and as a surgeon in the P. and O. Company, he entered the army as surgeon on August 1st, 1885, was placed on half pay on account of ill health on September 22nd, 1894, and retired on September 22nd, 1899. He served in one of the Balkan wars as director of the hospital at Raschka, and as physician of the arrondissement of Studenitza, Serbia.

Universities and Colleges.

UNIVERSITY OF CAMBRIDGE.

AT congregations held on June 18th and 21st the following medical degrees were conferred:

M.D.—C. J. Penny.
M.Chir.—F. W. Roques.
M.B., B.Chir.—R. D. Alexander, E. J. Greenwood, T. S. Dewey.
M.B.—F. W. Law.

UNIVERSITY OF LEEDS.

THE Council has conferred the honorary distinction of Emeritus Professor on Sir Berkeley Moynihan, Bt., P.R.C.S., who recently retired from the Chair of Surgery.

VICTORIA UNIVERSITY OF MANCHESTER.

THE Council have accepted the resignation of Miss Muriel M. Nutt, M.A., Demonstrator in Bacteriology.

The following appointments have been made: *Lecturer in Bacteriology*: Mr. A. W. Downie, M.B., Ch.B.Aberd.; *Demonstrator in Anatomy*: Mr. J. M. Yoffey, M.B., Ch.B.Manch.

The Turner Medical Prize has been divided between Muriel M. Edwards and Josephine Walmsley.

UNIVERSITY OF DUBLIN.

THE election of three representatives to the Dail has resulted as follows: Professor William Thrift, Fellow of Trinity College, Sir James Craig, M.D., F.R.C.P.I., King's Professor of Medicine, and Professor E. A. Alton, Fellow of Trinity College. The electorate numbered 2,069; the total poll was 1,589; the "quota"—under proportional representation—was 328. There were four candidates for three seats. The result leaves the representation of the constituency precisely as it was in the last Dail.

QUEEN'S UNIVERSITY, BELFAST.

PROFESSOR R. J. JOHNSTONE, M.P., has been appointed to represent the University on the General Medical Council, vice Colonel Sinclair, C.B.

Dr. J. B. Moore, F.R.C.S.I., senior surgeon to the Mater Infirmorum Hospital, Belfast, has been co-opted a member of the Senate.

ROYAL COLLEGE OF SURGEONS OF EDINBURGH.

AN extraordinary meeting of the College was held on June 14th, when Dr. A. Logan Turner, President, was in the chair.

The following were elected honorary Fellows in celebration of the centenary of the birth of Lord Lister, which will be commemorated in Edinburgh during the Annual Meeting of the British Medical Association next month: The Earl of Balfour, K.G., O.M., Sir William Watson Cheyne, Bt., Professor Harvey Cushing (Boston, Mass.), Professor Tuffier (Paris), Professor John Stewart (Halifax, Nova Scotia), Sir Robert W. Philip, M.D., President-elect of the British Medical Association, Dr. George M. Robertson, President, Royal College of Physicians, Edinburgh.

Obituary.

A. H. FREELAND BARBOUR, M.A., B.Sc., M.D., F.R.C.P., LL.D.

THE death occurred on June 11th, at his residence in Edinburgh, of Dr. A. H. Freeland Barbour. Dr. Barbour's death took place with a happy absence of any suffering. He had been in ordinary health and the best of spirits, and was engaged in signing letters when he suddenly fell forward and expired.

The reputation given to the Edinburgh Medical School by the genius and personality of Sir James Y. Simpson has ever been a stimulus to his successors in the department of obstetrics and gynaecology. The names of Sir A. R. Simpson, Sir J. Halliday Croom, Dr. Brewis, Dr. Berry Hart, Dr. A. H. Freeland Barbour, Dr. Milne Murray, Dr. J. W. Ballantyne, and Dr. Haultain are all written large in the history and development of gynaecology and obstetrics. Dr. Barbour was the last survivor of this distinguished group of men who flourished together in Edinburgh for many years, and whose united labours did much to enhance the reputation of the Edinburgh Medical School. Although he had retired from active professional work for some years, Dr. Barbour continued to take a keen and active interest in all matters connected with the university and other medical institutions in Edinburgh, and he was looking forward with great interest to the meeting of the British Medical Association in Edinburgh next month. Although he had never been of very robust constitution, his many friends had every reason to hope that he would long be spared to help them by his ready support and advice. He was not only a distinguished and honoured member of the medical profession, but his death will be mourned by a very wide circle, since his interests were catholic and his friends outside the profession correspondingly large in number.

DR. A. H. FREELAND BARBOUR.
(From a portrait by P. de Lazlo.)

Dr. Barbour was the youngest son of the late G. F. Barbour of Bonskeid and Gryffe, and was born in Edinburgh, where he was educated, graduating M.A. in 1874, B.Sc. in natural science in 1877, and M.B. with honours in 1879. From this time he devoted his attention to obstetrics and gynaecology, attracted to it doubtless in large measure by his association with his brother-in-law, the late Professor A. R. Simpson, whose assistant he shortly afterwards became in succession to Dr. Berry Hart.

After studying at various clinics in Germany, France, and Italy, he threw himself whole-heartedly into the preparation, with his lifelong colleague and friend Dr. Berry Hart, of the famous *Manual of Gynaecology*, which, when first published in 1882, marked a distinct epoch in British gynaecology. In the preface the authors stated that in writing the book they had tried to keep before their eyes the great principle that the anatomy, physiology, and pathology of the pelvic organs formed the foundation of good clinical work. The want of such a textbook had been long felt, and it met with an instantaneous and well merited success; it may be said to have been the first scientific textbook in modern gynaecology, and on it many of its numerous successors were modelled. Embodying the views not only of the Edinburgh school, which the authors represented, but also those of America and the Continent, the book included a bibliography of recent literature on each subject treated, and a wealth of illustration which had hardly ever been attempted in a medical or surgical textbook. It was received among gynaecologists with acclamation, and attracted world-wide attention to the Edinburgh Medical School, which the names of Simpson, Syme, and Lister had already made famous. It ran through six editions, was translated into French, Italian, Spanish, and even Chinese, and was for many years the standard gynaecological textbook at home, in the Colonies, and in America.

In 1884 Dr. Barbour presented a thesis for the degree of M.D. on "Spinal deformity in its relation to obstetrics." This was awarded a gold medal, and was published later as a monograph with 36 lithographic plates. This work was the outcome of original investigations applied to much unused material in the medical museums of Edinburgh and elsewhere. Continuing his studies on the anatomy of labour, Barbour published, in 1889, the first edition of his *Atlas of the Anatomy of Labour, as Exhibited in Frozen Sections*. The final and much enlarged edition of this work appeared in 1896. He devoted an enormous amount of time and care to it, and it will be a lasting monument of his scientific zeal, skill, and industry. Its publication was received with the most generous appreciation both at home and on the Continent, where work on similar lines had already been done by Braune, Schroeder, and others. His latest book, *Gynaecological Diagnosis and Treatment*, was written in collaboration with his former assistant, Professor B. P. Watson, now of Columbia University, New York, and is still a popular student's manual.

In addition to these major treatises, Dr. Barbour wrote many valuable papers, which appeared from time to time in the *Transactions* of the Edinburgh Obstetrical Society and other periodical publications, and all bore the mark of his original and scientific mind.

As a teacher he had a long and distinguished career in Edinburgh, and no department of his work brought him greater enjoyment or called forth in him a deeper interest. He was appointed university assistant to Professor Sir A. R. Simpson in 1882, and became later an extramural lecturer on midwifery and gynaecology, worthily maintaining the high traditions of the Extramural School in his own depart-

ment. He also served a full term of office as gynaecologist to the Royal Infirmary, and as physician in the Simpson Memorial and Royal Maternity Hospital. He had a singular aptitude for clear and striking exposition of subjects upon which he spoke, and many generations of students will remember with gratitude his lucid and interesting bedside clinics. Dr. Barbour's great powers of holding the attention of his hearers were also well illustrated in the lectures he delivered from time to time to working men. These dealt with subjects such as "The body as a machine," and "The most wonderful pump in the world," and formed admirable little discourses on physiology. The *Primer of Midwifery* which he wrote for nurses displayed the same clearness of thought and exposition. On the institution of a lectureship on gynaecology in the university, when Sir A. R. Simpson retired he appointed Dr. Barbour to this post, which he held during the term of Sir Halliday Croom's professorship of midwifery. After the retiral of the latter, and before the appointment of Dr. B. P. Watson, Dr. Barbour for one year delivered the lectures to the university class both in obstetrics and gynaecology.

Dr. Barbour served a term of office as President of the Royal College of Physicians; and when he resigned his ward in the Royal Infirmary he was made honorary physician to the gynaecological department. Numerous honours from foreign institutions had come to him, and he was a corresponding Fellow of the Royal Academy of Medicine of Turin and of the Obstetrical Society of Leipzig. In 1906 the University of Toronto conferred upon him the LL.D. degree of that university.

Dr. Barbour was a man of deep religious conviction and wide and warm sympathy. He took a special interest in the students with whom he came in contact, and in the "nineties" of last century entered enthusiastically into the work which was carried out for them by his friend Professor Henry Drummond. He was recently president of the Indian Association, and was a warm friend of all students of Eastern races studying in Edinburgh. He was a constant supporter of St. George's United Free Church, in which his brother-in-law, Dr. Alexander White, was minister. In foreign missionary enterprise Dr. Barbour took a special interest, and his name was for many years associated with the Scottish Auxiliary of the Chinese Mission of the English Presbyterian Church, in the presidency of which he succeeded his father.

Medical research remained always very near his heart. The Freeland Barbour Fellowship, managed by the Royal College of Physicians, was founded by him in memory of his father, for investigations conducted in the laboratory of the Royal College of Physicians at Edinburgh. In the University of Edinburgh, also, he founded a Freeland Barbour Fellowship, to be awarded in each alternate year to the graduate who had taken the highest place in anatomy, physiology, and pathology, in order that he might be able to carry out research in the subject of midwifery. In the University of Toronto he had also founded a scholarship. Medical institutions, such as the Royal Infirmary of Edinburgh, the Royal Hospital for Sick Children, the Maternity Hospital, and many others, benefited greatly from his judicious munificence.

In 1889 Dr. Barbour married Margaret Nelson, elder daughter of the Hon. George Brown of Toronto. He is survived by his widow and by two sons and three daughters.

The interment took place in the Dean Cemetery, Edinburgh, on June 15th, and was attended by a large number of representatives, including Sir Alfred Ewing, Principal of the University of Edinburgh, the Fellows of the Royal College of Physicians, who wore their academic robes, and representatives from the Royal Infirmary and other institutions in which the late Dr. Barbour had been specially interested.

The following well known foreign medical men have recently died: Dr. EDMOND ROUFFART, founder of the Belgian Society of Gynaecology and Obstetrics, member of the Royal Academy of Medicine, and formerly Senator of Brussels, aged 71; Professor GIUSEPPE MARCARINI, an eminent surgeon of Genoa; and Dr. PETRINI-GALATZ, formerly professor of dermatology at Bucarest.

Medical Notes in Parliament.

[FROM OUR PARLIAMENTARY CORRESPONDENT.]

THE chief business of the House of Commons this week has been to pass the Trade Disputes and Trade Unions Bill through its remaining stages. The Government reserved June 24th for the report and third reading of private members' bills, one of them being the Midwives and Maternity Homes (Scotland) Bill.

In the House of Lords, on June 20th, Lord Cave outlined the Government's scheme for a reformed Second Chamber with half the numbers of the present House, some to be elected by the Peers from their own number and the rest to be nominated by the Prime Minister for a period of twelve years. On Tuesday the Bishop of Liverpool, by moving the second reading of the Liquor (Popular Control) Bill, initiated a debate on temperance, in which Lord Dawson of Penn joined.

A meeting of the Parliamentary Medical Committee has been called for June 30th, and Dr. Cameron, of the Metropolitan Asylums Board, may then address the Committee on vaccination.

On June 21st Mr. Rhys Davies presented a bill making further provision with respect to procuration, trading in prostitution, and kindred offences, and to disorderly houses and other premises. The bill would also extend and amend the Extradition Act, 1870, The Children (Employment Abroad) Act, 1913, and the Criminal Law Amendment Act, 1922. The bill was read a first time.

Liquor Control Bill.

Speech by Lord Dawson of Penn.

In the House of Lords, on June 21st, the debate was resumed on the second reading of the Liquor (Popular Control) Bill, introduced by the Bishop of Liverpool. It proposed to give to boroughs with over 50,000 inhabitants, and licensing districts, the right of deciding periodically whether they are to have no change from the present system of competitive ownership of the liquor trade, or whether the trade is to be reorganized under a system of public control somewhat on "Carlisle" lines, or whether the sale of intoxicants is to be abolished.

Lord Dawson of Penn said that the most drastic proposal of the bill was the option of prohibition. That was not necessary to the fabric of the bill, and was put in to satisfy the extreme temperance reformers, who had made no secret of their intention to withhold their support from the measure if it did not contain that option. If it were adopted there would be no opportunity for going back if it turned out to be a mistake. It might be too soon to say whether prohibition had or had not been successful, but so far as it had gone it seemed to show the need for caution before touching it in any way. In countries where it had been adopted it had produced bootlegging and more drinking among the young than existed before. A fresh view ought to be taken of the liquor question and the matter approached in a fresh way. Duress was the curse of this bill. If by common agreement the causes which were known to be increasing temperance were fostered, a result would be obtained in ten years which would not be gained in a generation by any other means. There was a serious danger of temperance reformers being the greatest obstacles to reform. There was ample evidence that the country was becoming more temperate. It was only necessary to go to the theatres, the cinemas, to the big restaurants, and to the bank holiday resorts to see that the amount of actual drunkenness was extremely little. He had never seen in recent years drunkenness of so terrible a character in this country as he had seen in prohibition countries. The evidence with regard to disease due to alcohol showed a steady improvement, so much so that the provisions made in the hospitals years ago were found to be no longer necessary. But there could be a great deal of harmful drinking without actual drunkenness and disease, and he was with the supporters of the bill entirely in saying that there was too much drinking still, and that efforts should be made to hasten the movement towards greater temperance. There were grounds for encouragement in observing the habits of a large and important section of the community—the people with moderate means, who gathered in popular restaurants which had a full licence. A full inquiry three years ago showed that of the people who congregated in certain big restaurants 75 per cent. had no alcohol at all, and, of the 25 per cent. who did drink, no less than three-quarters were drinking either light wine or beer, and only one-quarter whisky or port. That was a very striking testimony to the progress of temperance and of real sobriety. He had made it his business, when he knew this debate was coming on, to inquire whether these figures had become better or worse. The answer was that in one restaurant the number of people who took liquor had gone down from 25 to 17 per cent., and in another it had fallen to 7 per cent.

In all investigations as to the progress or not of sobriety, it was the best and the fair way to make a division between the

age of 35 and under 35. After 35 people's habits were formed, and if a man became a drinker by then he was very likely to go on. What really mattered in this country was What were people doing who were under 35? He adopted that method in his next inquiry, and went among the clerk class. Taking the clerks over 40, he found that 21 per cent. were abstainers, and 40 per cent. of those under 40 were abstainers. That was in keeping with his own observations. The clerk class in this big city, especially the younger ones, drank remarkably little. If inquiries were made of those responsible for the young soldiers the same thing would be found. For instance, at Aldershot these young men came from their heavy drill in the morning about 11.30 or 12, and went helter-skelter to the canteen. Five out of six of them went to the dry canteen. It was an interesting fact that those who went to the dry canteen always asked for something sweet, showing that for the young sugar was a very good substitute for alcohol. He asked some of his friends in the army recently, and they told him, "It is absolutely true that the young soldier does not drink; you have only got to look at him to see that."

He had made it a point in the last few weeks of asking his business friends as to the drinking over business. It was quite true that it was far too rife. It was an essentially damaging form of drinking, because it involved drinking on an empty stomach, just like the cocktail habit; but it was going out, and was far less frequent than before.

In his inquiries he realized that he had not got down to the unskilled labour class, so he set to work, with some coadjutors well qualified in finding out what people did and did not drink, because in any big hospital the medical officers got to know what an answer meant, whether it was "Yes" or "No," pretty quickly. The records of something between 1,500 and 1,600 people of the unskilled labour class were examined. The results were so striking, and so much better than he expected, that he handed the papers to an actuarial friend. He (Lord Dawson) divided the total into abstainers, the temperate, and the imperfectly temperate. He was up against the difficulty as to what to make the threshold of temperance. He chose the figure 2, by which he meant to denote two drinks. He took the standard of a pint of beer or one glass—not a full one—of whisky. He found that if he took people under 35 and added together the temperate people and the abstainers they amounted to 90 per cent., and the imperfectly temperate were 10 per cent. There was a change after 35, when the temperate people and the abstainers came to 71.5 per cent. and the imperfectly abstaining people to 28.5 per cent. Taking abstaining people alone, under 35 there were 51 per cent., and over 35 only 22.5 per cent.

It was open to people to say that the reason why the percentage of temperate persons was less after 35 was that people grew into drink. That was a fallacy. People did not become drunken or intemperate if once they had acquired temperance habits up to 35. It was comparatively rare for intemperance to break out after that age, except under stress of circumstances wholly outside the present consideration. That gave food for thought, and showed that our people were becoming steadily more sober in their attitude towards alcohol. It was really an outrage to call this country a non-sober country.

It was said that the diminution of drinking was due to restricted hours and higher prices. He agreed that restricted hours promoted temperance. He would support the continuation of the restriction of hours, provided that it was made uniform in all districts; but the influence of higher prices was not worth talking about. Did a man stop drinking because he had no money? He made his wife go without money. If drink had got such a hold on him he would not stop because of the price. What had produced the change to which he had referred was better housing; this was shown by the fact that so soon as better housing was obtainable there was an improvement in respect to drinking. The next fact was the increasing love of fresh air and the constant desire on the part of the people to be out in the country. Then there was the greater companionship of men and women; but he would put above all others the very great love of physical fitness at the present time. The women had become more athletic owing to the adoption of more sensible clothing, and that had created a desire for physical fitness. Advantage should be taken of all those forces which he had mentioned. Education should be fostered, and the improvement of houses should be continued, and the chances of those who were less well off to enjoy games and outdoor sports should be increased.

If all these things were done for ten years, and if health lectures were given all over the country, then, not by fanatics preaching against the evils of this, that, and the other, but by people teaching what health meant, what good food meant, and what the disadvantages of alcohol really were, as well as its advantages, an appeal would be made to the convictions of the people, and far greater success would attend any campaign for temperance than by the provisions of a bill such as that before the House.

The Earl of Onslow said that the Government were heartily in concurrence with the wishes of the supporters of the bill, and were no less desirous than they for judicious reform. They could not, however, at the present time assent to a measure which involved the reopening of the controversial question of the amendment of the licensing laws. The report of the Southborough Committee on disinterested management had only been in the hands of the Government a short time. There were other matters connected with the licensing laws, not dealt with in that report, which it would be necessary to consider before any Government could give a pronouncement on the subject.

The debate was eventually adjourned.

Shop Acts, 1920 and 1921.

At the meeting of the Shops Committee on June 16th, evidence urging that the Early Closing Acts should be made permanent was given by representatives of the Joint Parliamentary Committee of the retail repairing boot trade (employers and employees). The witnesses declared that their trade was one in which boots, dusty and germ laden from the streets, came into direct contact with the worker. Consumption was rife amongst the operatives, as also were gastric troubles. The witnesses stated that their organization had taken medical surveys of consumptives in the trade. The Boot Trade Benevolent Society had recently made arrangements with a convalescent home for the treatment of consumptive cases. Of the deaths among boot and shoe trade operatives an average of 23.7 per cent. were due to tuberculosis.

Mr. Huntrods, president of the Incorporated Society of Pharmacy and Drug Store Proprietors in Great Britain, in a letter, argued that the necessary calls on pharmacy proprietors out of hours were very few, and that doctors had the prerogative under the National Health Insurance Act of supplying patients with really necessary medicine.

The Committee adjourned till June 30th, which will be its last public meeting.

Public Health in India.

On June 17th the House of Commons considered the Indian Estimates in Committee. Mr. Wardlaw Milne said conditions in India were better than ever before. The number of people who died of famine or starvation was infinitesimal. Immense work had been done—largely by British enterprise and under British leadership—for the relief of famine areas, by the promotion of irrigation schemes, and to deal with outbreaks of plague and cholera. Mr. Saklatvala referred to what he termed the crushing infantile death rate in Bombay. Mr. Pilcher said that the white population in Bombay, which was a tiny, infinitesimal minority, had done everything it could to improve the shocking slum conditions which existed in the city. Early marriage, when the girl was only 13 or 14, was the practice in India; it was believed that a child must be born of such a marriage as soon as possible, and that as many children as possible should be born. These were the root causes of the misery, not only in India but in China.

Mr. Johnston said that in Bengal 71 per cent of the males died before they reached 30. Malaria was rampant, and even if those attacked did not die they were weakened by it. It was questionable whether one man in a thousand of the agricultural population of India went to sleep at night after having eaten one decent meal during the day. Earl Winterton, in a brief reply at the end of the debate, said it had been agreed that when the estimates were taken again he should make a general statement on Indian matters. An amendment to reduce the vote was rejected by 173 votes to 45, and the debate was adjourned.

Poisoning of "Vermin."

On June 17th the Protection of Animals (Amendment) Bill was considered in Committee; the bill amends the Protection of Animals Act, 1911, which makes it an offence to put down poison. Dr. Shiels moved two amendments, the first of which substituted for the word "vermin," which may, under the bill, be destroyed by the laying of poison, the words "insects and other invertebrates, rats, mice, and other small ground vermin." He said that on the second reading he objected that "vermin" was too vague. He understood that his amendment was agreeable to the promoters of the bill. His second amendment was to include wild birds among creatures to be safeguarded from poison. Both amendments were accepted, and the bill passed through Committee.

Vaccination of Small-pox Contacts.—Answering Mr. Groves, on June 20th, Sir Kingsley Wood said that of patients recently admitted to the small-pox hospitals at Dartford and Yeading only one (as to the diagnosis of which there was some doubt) was vaccinated after removal to hospital. In this case the vaccination was unsuccessful. None of the patients were vaccinated after they were discovered to be suffering from small-pox. Two of the patients were vaccinated after contact with a case of small-pox, but in both instances too late to protect them from the disease.

The London Lock Hospital.—Answering Dr. Fremantle, on June 16th, Mr. Chamberlain said the London Lock Hospital was a voluntary one, and the general management of voluntary hospitals did not come under his review. Any grants to this hospital for specific services were made by local authorities, principally by the London County Council. The Council had given notice to withdraw its grant as a preliminary to a general review of its

rrangements for the venereal disease service. He had concurred i this proposed action. If the board of management asked for an iquiry into the general management of the hospital he would onsider the request.

Notes in Brief.

Answering Dr. Vernon Davies, Commodore King said that 101 oldiers were invalided for valvular disease of the heart in 1926. If these, 37 were under 21 years of age. During the present year o date 29 had been invalided, of whom 10 were under 21.

The Minister of Health doubts whether the time is ripe for a ommittee to inquire into the effect on the human system of noise nd vibration. Some aspects of the question are receiving attention rom the Industrial Fatigue Research Board.

Great Britain was free of foot-and-mouth disease from April 6th o June 16th, the longest period of freedom since 1921.

Thirty-nine cases of typhoid fever were notified in Gravesend luring the five weeks ended June 11th. A representative of the linistry of Health has visited the town.

Asked about the arrangements for aerating distilled water before upply to ships' companies, Colonel Headlam said the water was prayed through special roses into tanks.

The Minister of Health is considering whether the warning 'Unfit for babies," on tins of condensed skimmed milk should be nade more conspicuous.

The Minister of Health is not prepared to amend the law so as o make it illegal for the vaccination of children to be a condition n a tenancy agreement.

The statistics received by the Ministry of Health show a considerable decrease since 1911 in the death rate from tuberculosis in each of the six counties of North Wales.

Answering Dr. Vernon Davies, on June 20th, Sir W. Joynson-Hicks said the Government had not yet considered the unanimous recommendation of the Medical Research Council that the section of the Dogs Act, 1906, which forbids the use of stray dogs for research, should be repealed.

Answering Dr. Vernon Davies, on June 20th, Sir Samuel Hoare, in a written reply, said that 14 men were discharged from the Royal Air Force for diseases of the heart in 1926. Of these, 4 were under 21 years of age, and 2 of the 4 had a definite history of rheumatism. In 1927 to date 8 had been discharged, 2 under 21 years of age.

On June 21st Mr. Wellock withdrew the allegation he had made in a previous question that British military authorities were providing brothels for troops in China.

On June 21st Mr. McNeill told Captain Crookshank that holders of off-licences were not permitted to sell single half-bottles of spirits to their customers, even in case of illness. Certain members had put down for the Committee stage of the Finance Bill a clause proposing amendment of this law.

Medical News.

WE have received an illustrated pamphlet, entitled *Scotland's Wonderland*, describing Messrs. MacBrayne's steamship tours through the Western Highlands and Islands of Scotland. It gives a very complete account of the method of visiting these beautiful and romantic spots, together with the times and fares of the steamboats. It should be of great use to members of the British Medical Association who wish to extend their visit to Edinburgh in July. A copy can be obtained post free from Messrs. David MacBrayne, 119, Hope Street, Glasgow.

THE first annual Macalister Lecture of the London Clinical Society will be delivered by Sir Thomas Horder, Bt., M.D., at the London Temperance Hospital, Hampstead Road, N.W., on Thursday, July 7th, at 8.45 p.m. The subject of the lecture will be diet and dietists. A cordial invitation to the lecture is extended by the society to any medical practitioner.

MR. B. G. PETERS, M.Sc., has been appointed by the Grocers Company to a Grocers Research Scholarship in sanitary science, tenable in the division of medical zoology at the London School of Hygiene and Tropical Medicine.

THE DUKE OF CONNAUGHT, who for twenty years has been president of the Westminster Ophthalmic Hospital, will lay a commemoration stone in the entrance hall of the new building in Broad Street, Bloomsbury, on Thursday next, June 30th, at 4 p.m. The building has as yet only reached the first floor, but will eventually have eight stories; it is to be ready for occupation by March 25th, 1928.

THE Bearsted Memorial clinical theatre at the London Hospital will be opened by Viscount Bearsted on Wednesday, June 29th, immediately after the distribution of prizes.

A LECTURE entitled "Training defective children to become useful citizens," by Maria Montessori, M.D.Rome, D.Litt., will be given under the auspices of the London School of Medicine for Women, in aid of the Royal Free Hospital Centenary Fund, at the Æolian Hall, Bond Street, W., on Tuesday, July 5th, at 5.15 p.m. The chair will be taken by Lady Barrett, C.B.E., M.D., M.S., dean of the Medical School. Tickets for reserved seats (7s. 6d. and 5s.) may be obtained from the Medical School, 8, Hunter Street, W.C.1. Admission 2s. 6d.

DR. B. DUNLOP asks us to announce that on July 26th the Malthusian League (120, Victoria Street, S.W.1) will celebrate its fiftieth anniversary by a dinner at the Holborn Restaurant, and the public is invited to apply for tickets (10s. 6d.). Among the speakers will be Mr. H. G. Wells, Mr. J. M. Keynes, and Mrs. Annie Besant, who was the first secretary of the society.

THE Fellowship of Medicine and Post-Graduate Medical Association announces that Dr. C. M. Wilson will give a clinical demonstration at St. Mary's Hospital on June 29th, at 2 p.m., and at 1.30 p.m. that day Mr. Cairns Forsyth will give a surgical demonstration at the Royal Waterloo Hospital. On June 29th Mr. A. D. Griffith will give a demonstration in ophthalmology at the Royal Eye Hospital at 3 p.m. All these demonstrations are free to members of the medical profession. An all-day intensive course will be provided by the staff of the National Hospital for Diseases of the Heart from July 4th to 16th, and the daily sessions will start at 10 a.m. and continue until 4 p.m. As the course is limited to twenty, early application is desirable. For those desiring instruction in medicine, surgery, and the specialties the Prince of Wales's General Hospital undertakes an intensive two weeks' course from July 11th; the clinical practice of the hospital is open to those taking the course, and on each of the Saturdays visits may be paid to the mental hospital at New Southgate and the fever hospital at Homerton. From July 11th to 30th inclusive a course in proctology will be available at St. Mark's Hospital. Two demonstrations weekly (Wednesdays and Saturdays) will be given at the Park Fever Hospital from July 13th to 30th inclusive. From July 4th to 30th the West End Hospital for Nervous Diseases will hold a late afternoon course daily at 5 p.m. Copies of all syllabuses and the *Fellowship Journal* may be had from the Fellowship of Medicine, 1, Wimpole Street, W.1. A general course of work is also provided at the associated hospitals, for which a comprehensive ticket is issued and a separate programme published.

THE new Queen Alexandra wing of the Ealing King Edward VII Memorial Hospital was opened by Princess Mary, Viscountess Lascelles, on June 8th. The new wing, erected at a cost of £25,000, consists of two large wards of twenty beds each, with the requisite sanitary block, sixteen additional bedrooms for the staff, and one new private ward.

THE foundation stone of the Nicoll memorial wing of the Queen Mary's Hospital for the East End was laid by the Lord Mayor of London on June 8th. The extension will provide accommodation for thirty-two extra beds, of which twenty will be allotted to casualty patients. It is intended to serve as a memorial to the late Dr. P. J. S. Nicoll, for many years chief honorary medical officer and vice-chairman of the hospital. The additions are estimated to cost £35,000.

THE President of the French Republic has conferred the Order of Chevalier of the Legion of Honour upon Dr. Eleanor Hodson, of Canterbury, in acknowledgement of the service she rendered France as a member of the British League of Help. Dr. Hodson has already received the French Médaille d'Honneur.

MANY of our readers know of the medical visits (Voyages d'Etudes Médicales) to French health resorts arranged year by year by the Faculty of Medicine in Paris; there will be such a visit this year to the Eastern Pyrenees. The party will assemble at Balaruc on September 1st and go on that evening to Lamalou. A dozen resorts will be visited and the party will reach Luchon on September 9th; it will separate on the following day at Superbagnères. The greater part of the journey will be made by motor car. Further particulars can be obtained from Madame Juppé-Blaise, Federation of the Health Resorts of France, 19A, Tavistock Square, London, W.C.1.

THE late Mr. Lewis Spokes Richards of Edgbaston has bequeathed £1,000 each to the Birmingham Children's Hospital and the Royal Orthopaedic and Spinal Hospital, Birmingham, and £500 each to the Birmingham Eye Hospital and the Birmingham Ear and Throat Hospital. Under the will of Mr. William Bedlam of Littlehampton, who died in March last, the Littlehampton and District Hospital receives £1,000 and the Crawley Cottage Hospital £300.

A TOTAL of 6,787 cases of puerperal fever was notified in Germany in 1926, as compared with 7,003 in 1925; the incidence is highest in Hamburg.

TWELVE cases of trichinosis with two deaths occurred in Germany, exclusive of Mecklenburg-Schwerin and Hesse, in 1926, as compared with nine cases in 1925. Eight occurred in the Coblentz district, two in Bavaria, and two in Saxony.

THE cases of small-pox reported in the United States in 1925 numbered 41,643 with 702 deaths. In the last eight years Illinois alone has had over 30,000 cases, representing a community loss of no fewer than three million dollars. In the ten-year period 1916–25 Massachusetts had 253 cases of small-pox, with a community loss of 25,300 dollars.

Letters, Notes, and Answers.

All communications in regard to editorial business should be addressed to ***The EDITOR, British Medical Journal, British Medical Association House, Tavistock Square, W.C.1.***

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the BRITISH MEDICAL JOURNAL alone unless the contrary be stated. Correspondents who wish notice to be taken of their communications should authenticate them with their names, not necessarily for publication.

Authors desiring REPRINTS of their articles published in the BRITISH MEDICAL JOURNAL must communicate with the Financial Secretary and Business Manager, British Medical Association House, Tavistock Square, W.C.1, on receipt of proofs.

All communications with reference to ADVERTISEMENTS, as well as orders for copies of the JOURNAL, should be addressed to the Financial Secretary and Business Manager.

The ***TELEPHONE NUMBERS*** of the British Medical Association and the BRITISH MEDICAL JOURNAL are *MUSEUM 9861, 9862, 9863,* and *9864* (internal exchange, four lines).

The ***TELEGRAPHIC ADDRESSES*** are:

EDITOR of the BRITISH MEDICAL JOURNAL, *Aitiology Westcent, London.*

FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements, etc.), *Articulate Westcent, London.*

MEDICAL SECRETARY, *Mediscera Westcent, London.*

The address of the Irish Office of the British Medical Association is 16, South Frederick Street, Dublin (telegrams: *Bacillus, Dublin*; telephone: 4737 Dublin), and of the Scottish Office, 6, Drumsheugh Gardens, Edinburgh (telegrams: *Associate, Edinburgh*; telephone: 4361 Central).

QUERIES AND ANSWERS.

FACIAL ACNE.

"F.R.C.P." asks for advice in treatment of acne of the face in a young woman. Manganese, autogenous and mixed vaccines, unguentum iodi denigrescens, and ultra-violet light have been tried without success.

RECURRENT EPISTAXIS.

DR. O. W. D. STEEL (Llanbister, Penybont) asks for suggestions for the treatment of a girl, aged 7, who has suffered for two years with bouts of nose bleeding. At first the interval was three months, now it is only five weeks. Each attack lasts four days and there are three or four haemorrhages in twenty-four hours, chiefly by night. A year since she was seen by a rhinologist, who removed adenoids, but could find no local lesion to account for the bleeding. The coagulation time of the blood is normal. She has had calcium and adrenaline. Her father suffers from chronic bronchitis, eczema, and nasal polypus. Hitherto the haemorrhage has not been so severe as to cause anaemia. The fear and apprehension are doing harm, for she can tell when the bleeding is about to come on. She suffers nearly every spring from pneumonia.

TREATMENT OF BURNS.

DR. M. K. ROBERTSON (Kew Gardens, Surrey) writes with reference to Professor Fraser's lecture on burns (JOURNAL, June 18th, p. 1089): I find that before I see a burn it has always been covered with carron oil, olive oil, flour, or, as in a case I saw last week, a mixture of all three. Can anyone give me a satisfactory method of removing this oily mess, so that I may try one of the more modern methods?

BOOKS ON CHEMISTRY.

A MEMBER of a firm of food manufacturers asks whether any manual has been published within recent years on the lines of Attfield's *Chemistry: General, Medical, and Pharmaceutical* (1904).

*** Few of the more recent books on chemistry resemble Attfield's in its method of treating the subject. The expansion of chemistry and its cleavage into diverse branches have rendered Attfield's method incompatible with the newer plan of teaching, which has necessarily become more narrowly academic than before. Unless our correspondent obtains a comprehensive book such as Thorpe's *Dictionary of Applied Chemistry*, he may find it necessary to buy more than one, and may find the following deserving of examination: *Pharmaceutical Chemistry*, Bentley and Driver (Oxford University Press); *Chemistry, Inorganic and Organic*, Bloxham (Churchill); *Modern Inorganic Chemistry*, Mellor (Longmans, Green).

LETTERS, NOTES, ETC.

UNITED HOSPITALS' SPORTS.

THE fifty-sixth annual meeting of the United Hospitals' Athletic Sports was held at the Crystal Palace on the afternoon of June 15th. The weather was fine, the ground in good condition, and there was a fair attendance. Among those present were the President of the club (Dr. H. Morley Fletcher), Dr. Arthur Voelcker, who presented the prizes, Mr. E. B. Turner, who acted as timekeeper, Dr. Anderson, Deputy Medical Secretary of the British Medical Association, Dr. Scott and Mr. Stratford, secretaries of the Metropolitan Counties Branch. Dr. Anderson and Dr. Scott assisted in judging. The chief events, with the winners, were as follows:

One Mile.—R. A. P. Hogbin (Guy's); time, 4 min. 40⅘ sec.
100 Yards.—W. Hertzog (Guy's); time, 10⅗ sec.
Long Jump.—R. St J. Honner (London); 22 ft. 1 in.
Half Mile.—H. B. Stallard (St. Bart's); time, 2 min. 4 sec.
Putting the Shot.—W. Hertzog (Guy's).

The *Princess Louise Cup*, for the best individual performance, was presented to W. W. Craner (London) for winning the Quarter Mile race in 52 seconds.

The Cup given by Dr. C. F. T. Scott to the Metropolitan Counties Branch of the British Medical Association, to be presented to the best all-round athlete, was won by W. Hertzog (Guy's).

The Relay Race was won by St. Bartholomew's, and the Tug-of-war by the London Hospital.

MEDICAL GOLFING SOCIETY.

THE Medical Golfing Society held its annual summer meeting on June 16th at Walton Heath. All competitors were the guests of Lord Riddell and thoroughly appreciated his kind hospitality. There were over 100 entries. The competitions resulted as follows:

[illegible]. P. Kolesar.
—E. Playfair.
–V. E. Negus.
Kenneth Goadby tied with A. W. Soper. *Best last nine*: H. D. Gillies.

Class II.—First Prize: H. A. Chodak Gregory tied with G. Dawson. *Best last nine*: H. L. Hatch.

Foursomes.—These were won by J. O'Malley and W. Tindal Atkinson.

ILLUMINATION FOR FINE WORK.

AT the end of last year the Home Office published a report describing an inquiry made by Mr. H. C. Weston and Mr. E. K. Taylor on the lighting of printing rooms where hand composing was carried on. This was fully noticed in our issue of December 4th, 1926 (p. 1065). Mr. Weston has recently given an addres[s] at a combined meeting of [illegible]ng Society and the Joint Industrial [illegible]ades of the United Kingdom, in whi[illegible] The investigations, he said, were preparatory to the formulation of definite standards of artificial illumination for specific processes. The work chosen as suitable for the first experiments was type-setting by hand. Different illuminations on composing frames were taken, and the effect upon the speed and quality of the work noted. The test extended over a couple of days, and the compositors were employed in setting 7-point type (similar to that used in th s note). One fact which emerged was the effect of inadequate illumination in producing unnecessary fatigue; at the feebler illuminations the number of typographical mistakes was greater in the afternoon than in the morning, but this was no longer the case when the illumination was raised to a certain level (14 foot-candles). With an illumination of 7 foot-candles the rate of output was 10 per cent. below that obtained with a higher illumination. The best illumination for type-setting was found to be 20 fc[illegible] [illegible] frames and with this lighting the [illegible] to that obtained in g[illegible] machines was scarcel[illegible] type operator needed [illegible] if the matrices on the linotype and the small closely arranged figures on the drum of the monotype machine were to be seen easily an illumination of 20 foot-candles was not excessive. In one experiment tinted light was used, the fitting consisting of a white enamelled opaque bowl surmounted by a trumpet-shaped pale blue glass, intended to give approximately daylight correction without the coldness of north light. The compositors declared this method of lighting to be the best they had tried so far as restfulness and absence of glare were concerned, but they found it difficult to see old type, owing to the relative absence of shadows. Mr. Weston urged that the provision of adequate and suitable lighting in factories and workshops would benefit industry rather than impose an additional burden upon it. He agreed, however, that a certain number of industrial processes involved work of so fine a character that no kind of illumination would enable them to be carried out with entire efficiency and comfort, and in such cases the illuminating engineer could do no more than install really good lighting, and the ophthalmologist must be relied upon for further help in reducing strain associated with the work. In some industries the operatives had been provided with magnifying spectacles specially prescribed. Men with normal sight, however, did not appear to require magnifying glasses, and there is, or was, a reluctance on the part of compositors to resort to glasses, owing to the impression that they would be taken as evidence of failing sight and consequent unfitness. The fallacy of this idea, Mr. Weston urged, was apparent, and the use of glasses, when necessary, ought to be regarded as a natural and valuable means of maintaining, and even increasing, productive capacity.

VACANCIES.

NOTIFICATIONS of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals, will be found at pages 42, 43, 46, and 47 of our advertisement columns, and advertisements as to partnerships, assistantships, and locumtenencies at pages 44 and 45.

A short summary of vacant posts notified in the advertisement columns appears in the *Supplement* at page 272.

THE
British Medical Journal.
THE JOURNAL OF THE BRITISH MEDICAL ASSOCIATION.

EPITOME

OF

Current Medical Literature.

JANUARY TO JUNE, 1927.

F. W. W. GRIFFIN, M.D.,
SUB-EDITOR.

London:
PRINTED AND PUBLISHED AT THE OFFICE OF THE BRITISH MEDICAL ASSOCIATION,
TAVISTOCK SQUARE, LONDON, W.C.1.

INDEX TO THE EPITOME FOR VOLUME I, 1927.

READERS in search of a particular subject will find it useful to bear in mind that the references are in several cases distributed under two or more separate but nearly synonymous headings—such, for instance, as Brain and Cerebral; Heart and Cardiac; Liver and Hepatic; Renal and Kidney; Cancer and Carcinoma; Epithelioma, Malignant Disease, New Growth, Sarcoma, etc.; Child and Infant; Bronchocele, Goitre, and Thyroid; Diabetes, Glycosuria, and Sugar; Eye, Ophthalmia, and Vision, etc.

The Figures in this Index refer to the Number of the Paragraph, NOT the Page.

A.

ABADIE, C.: Vaso-constrictor and vaso-dilator drugs in therapeutics, 686
Abdominal incisions, rupture of, 338
Abdominal pregnancy. *See* Pregnancy
Abortion, treatment of, 380
Abortions, febrile, treatment of, 19. *See also B. abortus*
Abscess, latent cerebral, following mastoiditis, 293
Abscess of the frontal lobe following sinus disease, 455
Abscess of liver complicating appendicitis, 252
